NO. 1

Editorial

THE DEATH OF JAMES HEDDON.

We have just received notice that James Heddon, one of the best-known bee-keepers of 20 years ago, died at his home in Dowagiac, Mich., on Dec. 7 last. A biographical sketch will appear in our next issue.

GLEANINGS BEGINNING ON ITS 40TH YEAR.

A GLANCE at the bottom of the first cover page of this issue will show that GLEANINGS is now entering on its 40th year. The editor is also reminded that he is now entering on his 27th year at the editorial helm of this journal. Our managing editor, Mr. H. H. Root, has for 9 years selected most of the copy from our correspondents in the field.

SPECIAL ISSUES FOR 1912.

We call the attention of our readers to the fact that this issue, our "Beginners' Number," is the first one of a series of six special numbers. We are endeavoring to collect articles written by specialists that will furnish exceptionally valuable reading along the lines suggested. With this in view we are soliciting these articles from well-known authorities; for, although we have on hand more material than we can use for some time to come, it is always our aim to place before our readers the best that can be obtained.

The rest of the special numbers will occur as follows: February 15, "The Bee-keeper and the Poultry-man;" March 15, "Bee Culture and Horticulture;" May 1, "Preparing Colonies for the Harvest;" July 1, "Honey Harvesting and Marketing;" September 1, "Wintering."

In addition to these special numbers we are glad to announce a series of articles from no less an authority than J. E. Crane, of Middlebury, Vt., entitled "The Experiences of a Foul-brood Inspector." This series is illustrated, and we are sure it will prove valuable, not only to the foul-brood inspectors over the country but to all bee-keepers as well. Mr. Crane has had a long experience, and his position as an extensive producer of honey enables him to sift the wheat from the chaff as capably in these articles as he does in his regular department. There are eight articles in all, the first of which will probably appear in the February 1st

issue, the rest following in continuous order, with the exception, possibly, of the special numbers.

OUR COVER PICTURE.

THE picture on the cover of this number is suggestive of a beginner making his first start with bees. Notice the box containing the three-frame nucleus that he has just bought. One of the frames he has already transferred to the hive in readiness; the second one is just being lowered into position, while the third is still in the shipping-box. Those of our readers who made their start from a nucleus (and, in fact, those who started with a full colony) can remember the eagerness with which they watched for the arrival of those first bees, and the thrill they had in seeing them begin at once to fly in and out of the new hive. Of all the different lines of outdoor work taken up by suburbanites, or even residents of cities, we believe there is none more entrancing than that of caring for a few colonies of bees.

The extensive producers who may be styled professional bee-keepers, and who number their colonies by the thousands, can not afford to overlook the efforts of the amateur; for more than once such amateur, owing to his boundless enthusiasm and love of the revelation of nature which bee-keeping affords, has stumbled on to some new principle. Without beginners there can never be experts, for no man has yet been born with an inherited knowledge of bees and bee-keeping.

COMMON MISTAKES BEGINNERS ARE APT TO MAKE THE FIRST YEAR.

In any line of business there are some things that must be learned by experience; but in bee-keeping especially there are some difficulties that a beginner encounters that do not form much of an obstacle to one who has kept bees for a few years. While it is impossible to make a list of *all* the troubles that perplex beginners, and while explanations regarding them do not always take the place of the knowledge gained by real work in the yard, it is, nevertheless, profitable now and then to consider some of the mistakes that are most commonly made.

We will first take up the list of those that

are encountered at this time of the year.

First, a beginner, as he goes out among his outdoor-wintered colonies after the first warm fly day, on seeing the number of dead bees in front of the entrances naturally concludes that he is going to lose all his bees before spring. As a matter of fact, there is sure to be *some* mortality; and the stronger the colony the greater the number of dead bees that will be found.

Or we will suppose that Mr. Beginner has his hives in the cellar. Even when conditions are ideal, and he has complied with all the rules for safe wintering, he will find what appears to be an abnormally large number of dead bees on the cellar bottom; and again he is sure he is going to lose all of his bees. The fact is, there is bound to be a good many even when conditions are normal—especially toward spring. If he begins to tinker with his bees to see what is the matter, he will make matters ten times worse than they were.

Some over-enthusiastic novice may be inclined to open up his hives of outdoor bees every now and then to see how they are coming on. If they have been properly fed and properly housed, he will do well to leave them entirely alone.

Perhaps he is afraid they have not enough stores, and then he will try to feed them liquid syrup, which they will not take if the weather is at all cold. If the syrup is left on top of the cluster they will take it down the first warm day, and then they will fly out at the entrances to find more, only to become chilled and die on the ground. Feeding should not be practiced during winter except to give cakes of hard candy, queen-cage candy, or combs of sealed stores.

Sometimes a beginner on a cold day, looks down into his hive and finds a ball of bees only a little larger than his double fist, even in some of the best colonies. "My, oh my!" he concludes, "this will never do;" and so, perhaps, he will attempt to unite. He does not know, perhaps, that the strongest colonies—the very best that he or any one else may have—can compress themselves into a space almost as small as the double fist providing the weather is very cold.

Many a beginner makes the mistake of placing his hives on an exposed knoll where the cold prevailing winds can strike them. Apiaries should always be protected by being placed in an inclosure formed by a barn, out-buildings, fence, or shrubbery—any thing that will break the force of the wind.

In the spring of the year, one starting in bees reads what is said about spreading brood in order to get more brood. He undertakes to do work of this kind with insufficient knowledge of the requirements. The novice and most experienced bee-keepers should not undertake to disturb the positions of the combs in the early season. As a general thing it will do more harm than good.

Reading that bees should be stimulated in the spring by feeding, some beginners will feed when the weather is too cool or

when honey is coming in from fruit-bloom. No feeding should be practiced at either time.

Many beginners make the mistake, after having read all the bee-books, and keeping bees for a couple of years, of supposing that they "know it all" when they don't. Such people usually wander into the stage of inventing bee-hives or bee-feeders. They should understand that most veterans who know most about the business do not waste any time in trying to improve (?) on the basic principles put forth by father Langstroth. The fact is, nearly all the so-called improvements on the Langstroth frame and hive have been a step backward rather than forward. If our beginner friend clearly understands this, perhaps he will not get it into his head that he is going to revolutionize hives and appliances.

Another trouble with the beginner is that he is apt to be too impatient to get his crop of honey. He reads of some one's great success, or possibly hears his neighbor telling about putting on a super on such and such a day and taking off 32 full sections a little later, and he is perplexed because he can not get the same results. His bees seem to be working so steadily and so industriously that he can not understand why they don't go into the super on business intent; and at the very start he is apt to get discouraged, feeling that all the reading which he did has not prepared him for even this first emergency. He finds that the books recommend the use of "baits" in the supers to get the bees started, and he wonders whether a bait consists of a bunch of flowers, the sweet perfume of which would be attractive, or what. On reading further he finds that "baits" are unfinished sections containing some honey left over from the year before, or, possibly, merely sections with the comb pretty well drawn out. As he has just started, and has nothing left over from the year before, he wonders where he is going to get his bait. Meanwhile, the bees keep on flying merrily, but refuse to notice the tempting white sections above them with their starters of comb foundation.

WHY BEES DO NOT ENTER SUPERS.

As explained in the questions and answers under Heads of Grain in this issue, there are several reasons why bees do not go above for storing honey; and it may be any one of them or a combination of several. In the first place, it must be remembered that the tendency of the bees is to place honey as close as possible to the brood. It is much handier there, and far more convenient for winter. Estimates vary as to the actual amount of honey which bees consume themselves during a year; but assuming that it is 300 lbs., it is plain that the surplus honey—that is, that which is stored in the sections—forms only a relatively small percentage of the honey really brought into the hive. The super, then, is to the bees what the savings bank is to mankind—a storage-house for the surplus wealth accumulated during a period of prosperity. A colony that is not strong

and prosperous, therefore, is not capable of storing any great amount of surplus; and what they do store they prefer to place as near as possible to the brood in combs that the queen does not occupy, owing to the small number of nurse bees in the colony.

A colony with a failing queen rarely does much in the super; for if the queen lays less and less, the bees keep putting more honey in the cells left vacant by the hatching brood, and, finally, the queen has very little room to lay. Bees are creatures of habit; and when once they get started to storing honey in the brood-combs it is more difficult to get them to go to work above.

It is often the fault of the season that bees do not work in the supers; for unless the honey comes in with a rush so that the bees are able to store much more than they can possibly use they can not be induced to go into the sections. A beginner is often deceived in thinking that his bees are working hard, when, in reality, they are working only a little, or perhaps merely playing or loafing. During a good honey-flow, when a colony is working well, the heavily loaded bees have no time for play, and they drop down on to the alighting-board and immediately crawl into the hive in such numbers that it is impossible to count them. At such times the field bees forget every thing except work; and they are so busily engaged that they have no thought, except the one mad desire to bring in more and more. Under these conditions, unless they get sidetracked on to swarming there is generally very little difficulty in getting them into the super provided the brood-combs are pretty well filled with brood, so that there is not much room for the storage of surplus honey there.

THE SWARMING PROBLEM.

Some beginners are perplexed because their bees won't swarm, and others because they swarm too much. It is a question whether the beginner, the first year at least, should attempt any form of artificial increase; for the natural-swarming method is the best for one who lacks experience; and one swarm in a season is all that should be allowed. The books describe fully a number of good plans for preventing after-swarms—that is, all swarms after the first one, which is called the "prime" swarm.

GETTING HONEY AT THE EXPENSE OF COLONY LIFE.

After the honey-flow the most costly mistake that the beginner can make is to leave his colony or colonies, as the case may be, in poor condition for winter. A rather weak colony, composed mainly of worn-out bees, is not likely to live through the winter, no matter how securely the hive is protected, nor how well supplied with stores the combs are. If there is no fall honey-flow, of if the queen does not keep up brood-rearing long enough to insure a good force of young bees to go into winter quarters, some feeding is necessary; and here it is that the beginner often blunders. He is not well enough post-

ed on methods of feeding as given in the books, and perhaps his first difficulty occurs soon after beginning to feed. He is astonished to find that the bees become very irritable, and commence fighting, apparently, among themselves. The real situation is that the feed, instead of being supplied in the evening, is given in the morning; and during the excitement other bees from some other hive or from some bee-tree in the locality are attracted, and robbing is the result. Wholesale fighting begins, and many bees are killed. At this time they are so cross it is almost impossible to do any thing with them; and even dogs or horses that get in their way are apt to be stung. During a dearth of honey great care is necessary to prevent spilling any syrup or leaving any exposed sweets around to invite robbers.

DO NOT WINTER IN A CLOSED ROOM ABOVE GROUND.

If a colony is wintered in a place where the temperature changes very much, the bees must have an opening to the outside air. In other words, the inside of a barn or granary is not a fit place for a colony of bees in the winter unless the hive is placed close to the outer wall and an opening made for the alighting-board so that the bees may fly when the weather is suitable. In a cellar where the temperature does not change very much, seldom going below 40 degrees nor above 50 F., it is not necessary to have the outside entrance; but for best results the room should be darkened.

Colonies that are wintered on their summer stands out of doors need some protection where the temperature in winter goes down to zero; but the outer packing material must be protected from the rain, so that it may not soak through and then freeze. Old carpets, sacks, etc., thrown over a hive are worse than useless unless covered with a water-proof box which will keep the packing dry.

Summing up the whole question, we may say that all mistakes commonly made by beginners may be classed under two heads: First, failure to bring the colony into the right condition by the time the main honey-flow begins; second, failure to have the colony in the right condition for winter. Mistakes under the first head mean a loss of the crop; and those under the second mean the loss of the bees themselves. Both are costly, and both are preventable; and it is profitable for any bee-keeper to "go slow" in order to learn how to prevent such trouble before making a large increase in the attempt to produce larger and larger crops of honey.

A very common mistake of some *prospective* beginners is to imagine that the flowers in their back yard, consisting of a few roses, dahlias, sweet peas, etc., are going to yield enough honey to fill their hives. Such people should know that a single colony of bees requires acres of good bee forage in order to store any surplus. The ornamental flowers of the garden yield practically no nectar.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

LOUIS SCHOLL'S "Honey vs. Other Sweets," page 747, would be a fine thing to have copied in local papers.

C. A. NEAL, page 766, asks where he can buy rock candy. Sears, Roebuck & Co., Chicago, quote it at 65 cts. for 5 lbs.

D. W. MILLAR, p. 718, talks about European foul brood, and then says, "We do not consider this contagious." If it isn't contagious, it isn't European foul brood.

THANKS, Mr. Editor, for your invitation to eat pie with you, p. 746. At a banquet the talking comes usually after the feast. Let's reverse the order, and talk before cutting the pie.

A. W. YATES, those "little drops falling like rain," p. 717, were only water separated by the bees from the syrup. Don't you for a minute think bees will throw away good stuff they have once started with. [Right you are.—ED.]

REV. GEO. W. FULLER, *Review*, 339, reports that in York State, last year, he found lice on a number of bees, each bee having from one to eight lice. Heretofore the bee-house has never flourished in this country when brought across the sea.

DEVAUCHELLE, *L'Apiculteur*, 412, fully endorses the view expressed by you, Mr. Editor, page 712, about Abbe Pincot's enlarged bees. Abbe Pincot says they are 13mm. in length, while his unimproved bees are 12mm. Devauchelle's bees, reared in ordinary cells, are 14mm. long!

J. G. CREIGHTON wants to know the origin of the first golden queen. I think Doolittle obtained his from Italians by constant selection of the brightest-colored bees. I believe others have been obtained from Cyprian or other stock—perhaps with some crossing. [If we are not mistaken, friend Doolittle was not the first to bring out the golden Italians. We hope the man who did it will speak up.—ED.]

SOME have complained that foundation has dropped out when wedges were used. Stephen Anthony has overcome the difficulty by cutting each wedge in 3 pieces, using two of these pieces to each frame, starting about $\frac{3}{4}$ inch from each end.—*Review*, 345. [One difficulty with many is that the precaution to drive the wedge *below* the surface of the wood its *entire* length is not observed. The wedge should always go the full depth of the groove.—ED.]

DR. PHILLIPS had barrels of slumgum attacked by moths. Just what I should expect here if the barrels were warm enough and exposed enough. But we were not talking about slumgum on p. 582. To be sure, you asked a question on that page in which I think you had reference to brood-combs; and as that has not been answered,

I'll be liberal enough to answer it here. You asked, "Is it not true that, when these combs have been frozen, after a long severe winter, they will develop the moth-worm without ever going back into the hives again if left exposed in a building?" In this locality a brood-comb that has been exposed to a winter's freezing, if left standing in the apiary in a hive without any bees throughout the summer, will not be troubled with moths one time in a hundred. My assistant says she doesn't remember a single case. I can't say how it would be in a building. But neither slumgum nor brood-combs are involved. Let's see just what is the material for that pie. I said, in effect, p. 582, "I venture the guess that S. D. House never had an egg laid in sections after they were taken from the hive—at least that, I think, is the case here." So please bear in mind that neither slumgum nor brood-combs are to go into that pie—only sections. Now I'll tell you on what I base that guess. For years I have had each year hundreds if not thousands of sections, with combs partly or fully drawn out, that were stored in the shop. The moths could easily get them if they so desired. They were put there in the fall and stayed there generally till June, sometimes through the entire summer, and I do not remember ever to have seen a single one of those sections troubled with moth-worms, and I have good eyes too. If, now, my experience is entirely exceptional, and every one else, especially S. D. House, says such sections are destroyed by worms, you needn't mind cutting the pie. I'll eat the whole of it and look pleasant while eating it. [Are you not making a distinction, doctor, without a difference? For example, what is the difference between a comb in a brood-frame and a comb in a section? Both may or may not have had brood in them. But let us assume that there *is* a difference. If you will turn back to our original statement, page 547, Sept. 15, you will see that we were talking about the possibility of moth-millers laying eggs "in his combs or in his nice comb honey after either has been taken from the hive." In your comment on this, page 582, you said sections. The natural inference would be you included in your guess combs either in the sections or brood-frames. Now, then, doctor, if the moth-miller will attack or lay eggs in combs after they have been frozen or fumigated, why should she not lay eggs in combs built in sections?

As we look at it, your proposition or "guess" will be an unsafe one to let go unchallenged before the bee-keeping public. Don't you believe there is plenty of proof now to show that it would be wise to err on the safe side—at least so far as our instructions to the public are concerned. The individual, of course, can do as he pleases.—ED.]

NOTES FROM CANADA

J. L. BYER, Mt. Joy, Ont.

Arthur C. Miller's article on page 664, Nov. 1, is interesting; but in some things he mentions, many of us will assume the "Missouri" attitude before being convinced. Certainly cotton for fuel does not act in the way friend Miller says when used with our bees. What a good thing that we have "locality" to fall back on! As to winter temperature within the hive, outside of the cluster, being within one or two degrees the same as outside the hive, is a question, but he may be right. If such is the case, one would wonder why bees winter so much better with abundance of packing than they do in single-walled hives, in our cold climate.

If all goes well I intend to test the matter myself this coming winter, during zero weather, as some of my hives are so constructed that a thermometer can be taken from the inside of the hive without unduly disturbing the cluster.

The advisability of compensation for colonies destroyed by inspectors is a question that comes up every once in a while when the foul-brood laws are under discussion. The following, from the *British Bee Journal*, written by that well-known author, D. M. Macdonald, hits the nail fairly on the head, according to my view of the question: "I have always been an opponent of compensation in any form. Of what value, I ask, is a putrid mass of vile-smelling matter? The most rabid must admit that it is represented by a cipher. So also must be a collection of combs fast hastening to this unenviable condition. Why, the party who eradicates disease or the cause thereof is the one who should be compensated."

The foregoing may be a bit too radical, so far as heading off European foul brood is concerned, because in some cases it might be economy to the state to compensate, where slightly infected colonies were destroyed, to prevent the spread of the disease; yet, in the main, Mr. Macdonald's views are reasonable, as colonies rotten with foul brood represent no money value outside of the wax that is in the combs. On the contrary, they are apt to be even worse than useless, and a menace to the welfare, not only of the owner, but his neighbors as well.

The Ontario convention was well attended, and in every way a success. From over the line we had the different ones mentioned in a former issue, as well as Mr. Geo. B. Howe, of Black River, N. Y. The convention was strictly a *business* one, and it was a question in the mind of some if this feature was not overdone a bit. While we may argue (as the writer has often done) that details of management, etc., should be discussed in local conventions, yet the fact seemed apparent at our late convention that many come to get information who are not as yet interested in freight rates, coopera-

tion, and a host of other questions that the more seasoned bee-keepers no doubt rightly think should be paramount. This fact was made clear by the lively discussion that followed any subject or question that would occasionally crop up concerning actual management connected with the apiary. To my mind it seems clear that we must be careful in future conventions, and not jump too quickly from one extreme to another, else there be danger of cutting out the attendance and interest at our meetings. This should never be allowed, as there is no question but that the social side of such gatherings must be taken into consideration.

It is an old saying, "All things come to those who wait;" but this fall, in our particular vicinity, the man who waited for his bees to have a flight before putting them in the cellar "got left" unless he did the work early in November.

At the east yard the bees had a good flight Nov. 6, and the 280 colonies were put inside on the 8th and 9th. Here in York Co. we had only 40 to go inside; and as the cellar is not of the best, we like to wait till late in November before putting the bees inside. On the 11th they had a partial flight; and on that day, wherever bees were outdoors, both east and west of us, they had a grand flight, as the day was warm and clear. Here with us it was quite warm but very cloudy all day. Little things like this show how it is possible for much different results in beekeeping in localities only a few miles away from each other.

However, we waited in vain for a warm day before putting these 40 colonies in the cellar; and about Dec. 1, when the thermometer showed nearly zero, the bees were put inside without having had the flight we were hoping for. After being in the cellar for less than a week the weather turned warm, and has been warm for over a week now; and at this date, Dec. 11, all the frost is out of the ground and some plowing has been done. One day the bees outside flew nicely, and only the thought of the *heavy* hives in the cellar prevented us from carrying out those 40 for a flight. This carrying out colonies in the winter for a flight sounds all right on paper, but is a different thing in practice when the hives weigh 70 lbs. or more each, unless you get the "other fellow" to do the work. When my son and I started to carry them in we had planned carrying them out on the first warm day; but by the time we had them in the cellar we had *changed* our minds, for we felt that *two* operations of that kind are enough for a lot of bees in one season. All things considered, I am of the opinion that, for our latitude, outdoor wintering is the best, and this opinion I note is being shared more fully by many men who are in the business extensively.

Bee-keeping Among the Rockies

WESLEY FOSTER, Boulder, Colo.

BEE INSPECTION DURING 1911.

Full reports have not been received from all counties; but more than twelve thousand colonies were inspected, of which something in excess of 10 per cent were found diseased. The expense to the counties and the State has been about \$2000.

THE HONEY SITUATION.

Colorado at the present time has been about cleaned up on comb honey, but we are well supplied with extracted. The latter is selling now for $7\frac{1}{2}$ to 9 cts. in 60-lb. square cans. Comb honey sells locally in small lots at about \$3.00 per case of 24 sections for No. 1 grades. The price tends to go above this figure, as the smaller beekeepers with but a few cases of honey are getting pretty well cleaned up.

BANKING HIVES WITH DIRT.

Some of the bee-men near Rocky Ford are banking dirt up around three sides of the hives, and they claim to have good success. The Arkansas Valley country is very dry in winter, and this method might succeed there when it would fail almost anywhere else. The objections to this method are that the hives would tend to be dampened by the dirt, and then the hives and bottoms would be more subject to decay. Otherwise this wintering method might work all right.

A STARTERING-MACHINE.

Mr. D. S. Jenkins, of Las Animas, is the inventor of a machine which will cut, and in one operation insert in a section honey-box, a starter of any desired size. The Las Animas bee-keepers in that vicinity who have used it have discarded every other make, whether a combined machine or not. His is simplicity itself, and does not cost 25 cents for material. Mr. Jenkins has made and sold several for \$2.50 each. He uses an auto in his bee-work, and this, too, is largely of his own manufacture. He says one has to become accustomed to the machine for startering sections before being able to use it successfully.

TALKS ON BEES AT THE PUBLIC SCHOOLS.

The Colorado Agricultural College is conducting a series of farmers' institutes in the Arkansas Valley, Colorado. The writer is giving talks on bee management and foul brood at the institutes, and on the habits of the honey-bee, before some of the high schools and public schools. Courses in agriculture and domestic science are being carried on in many of the schools, and these classes are especially interested in the honey-bee and its product. In some places the whole school is dismissed while our corps of speakers are in town, and in other places we go to the schools and speak there. Institutes are being held at Wiley, Lamar,

Las Animas, Cheraw, Rocky Ford, Swink, La Junta, Fowler, Boone, Fountain, Sugar City, and several other towns.

WHAT OF THE NEW YEAR?

Some time ago my wife was looking through the bee-journals, hunting for her husband's bee material and remarks thereon by the other correspondents, when she said, "You bee writers don't do much else than nod back and forth at each other in your departments."

It struck me as being rather apt, even if my wife did say it. The reason, no doubt, is principally because of lack of better material. Each one of us who tries to keep his department going should have an experiment station in operation to furnish actual results as a basis for his results. It would do away with a lot of guesswork and mere ideas on certain subjects. But as we can not do this except as our own apiaries are experiment stations, we shall have to keep right on in the way we are going, with a constant endeavor to improve our methods and the material we furnish.

COLORADO BEE INSPECTION IN 1912.

Plans are being made to do thorough inspection in every county in Colorado where bees are kept if the county commissioners will set aside enough money to pay a county deputy inspector to work under the direction of the State Entomologist's office. Most of the counties are coöperating in this way; and if all will help, great good can be done. The bee-keepers in each county not having a local inspector should call a meeting of the bee-men at some time when the commissioners are in session, and appoint a committee to see the commissioners or else have the bee-keepers see them in a body. The writer, if notified, will gladly meet with the bee-men and take up the matter with the commissioners, explaining the way the new law operates, and the means of getting the most benefit from it. It is important to get this started soon, as the commissioners want to know some time in advance as to the expenses they will be called upon to vote for different kinds of county work, and the bee-keepers should not be at the tail end of the appropriations. The State funds are not sufficient to keep me in the field more than six or seven months; and when there are a dozen or more county inspectors at work the office work takes a great deal of time. However, I shall be able to put in one or two weeks in each county, working with the county deputy inspectors.

Let us all make an extra effort to get foul brood under control in Colorado. It can be done if we make an extra effort. In the future our work will consist in seeing that cleaning up is done. Inspection avails nothing if treatment is not given promptly.

Conversations with Doolittle

At Borodino, New York

THE APIARIST'S USE FOR AN AUTOMOBILE.

"Did you see the editor's request, page 709, December 1, that those having automobiles tell something of their experience with them in bee-keeping for the benefit of the GLEANINGS family? If I am correct, you were one of the pioneers in using the auto in connection with our industry; and as I am thinking of purchasing one I should be pleased to have you tell us about it."

"I bought my first automobile in June, 1903—a 3½-horse-power Pierce motorette. Automobiles were then in their infancy; yet this little machine could climb any of our hills, carrying a load of 400 to 500 pounds. As it was not intended for any thing but carrying two persons, I made a rack to fit on behind the seat; and with this, and the seat Mrs. D. occupied when both of us went, I could load on 350 lbs. of honey, or as many hives or supers as would stay on when going and coming to or from the out-apiary, five miles away. As I then weighed from 260 to 270 lbs., it will be seen what a power there was in that little 3½-horse-power motor. In September, 1905, I sold this motorette, considering it too small for my use with the bees; and as I was so well pleased with the material and workmanship I bought another Pierce car, this having a folding seat in front. This was styled an 8-horse-power Stanhope; but to show its power and capacity I will say that I have carried four grown persons and six children in it, besides myself, at Sunday-school picnics, and, at other times, from 600 to 800 lbs. of crated section honey, to our railroad four miles away, over a hilly country, when shipping my honey to the New York market. By opening up the front seat I could pile on nearly as many hives and supers as could be drawn by wagon, and take them to and from the out-apiary in less than half the time required to traverse the distance with a horse. Those having GLEANINGS for August 1, 1906, can find a picture of me with my load of supers just arriving from the out-apiary.

"But the great beauty of the automobile for the bee-keeper consists in the driver having perfect control in all of the essentials of apiary work. With my auto I can drive right into the bee-yard; and with the distance I have between the rows of hives, the auto can be brought right up to the back side of any hive; heavy supers, freed from bees by the use of the bee-escapes, set right from the hives to the auto, with a carrying swinging motion, with scarcely a bit of the lifting needed when loading on a wagon, as the auto is of about the same height as the supers on the hive. The motor may meanwhile be left running slowly, so that moving on to the next hive is only a matter of touching a lever; and in a very few minutes the load is on, the hives closed up in good shape, and we are off, without a sting or any worry from the bees whatever.

"Then the driver of this load of precious sweets is always master of the situation, if he is a capable driver, no matter what he meets on the way home. Once a hog was the cause of frightening my horse, and again a traction engine, so that it was only by a hair's breadth that the load of honey was not demolished. The auto never shies nor gets scared, no matter how many ghosts jump out in unexpected places.

"Another thing which really gives me lots of comfort is, the flies never bite and torment the auto, as they are sure to a horse during the season for moving honey. This season is always in fly time; and to control the horse when flies are very troublesome is not always the easiest thing to do where the road is very rough and stony; and a horse often gets its tail over the lines in the fight to relieve itself from these tormentors. It is needless to say that the auto overcomes all of these many difficulties.

"The auto can be made to go at snail's pace where the load requires the most careful driving, and, where good, a fifteen-miles-an-hour jog is just as safe and reasonable as the former. Thus a load can be moved with an auto, without tying or binding when moving, which is always a safe precaution with a horse and wagon.

"Another thing about the auto which pleases me nearly as much as does driving it right into the middle of the apiary, without fear of stings or the unhitching of horses, is this: After finding what this auto would do I built an auto store-room, honey-room, and small workshop combined, with movable partitions, painting the same a dark color so as to ripen the honey when stored therein through the heat brought about by the absorption of the rays of the sun. Now, instead of having to carry the honey from the wagon to the honey-room, the auto load of honey is run right into the honey-room. This saves a whole lot of lugging which was necessary with each load when returning with the horse-drawn wagon. Again, when marketing with horse-power the crates of honey must be carried from the honey-room to the wagon standing outside, and the load, when completed, securely tied or bound on, owing to the smooth surface of the nicely polished cases. The auto is backed right into the honey-room, between the piles of nicely crated honey, when, with the swinging motion, the honey is conveyed from these piles into the auto; and when the load is on, the driver pulls the lever, and he with the load moves right out from the honey-room to the railroad station or car conveying it to where it is consigned.

"To save any tying when carrying polished cases of honey to market, I have properly shaped pieces of lumber put in the auto where needed, to give a very slight tip or pitch toward the center, so that all crates will gravitate toward the middle of the load, which is even better than tying."

WHAT A LIFETIME OF EXPERIENCE HAS TAUGHT ME.

Some Advice for the Especial Benefit of the Beginner.

BY ISAAC F. TILLINGHAST.

Born on the even half-century mark, January, 1850, it is now over sixty years since I first opened my eyes to the beauties of this diversified world, and began the study of nature. Among my earliest recollections is a row of Week's patent hives. My father kept them in his front yard suspended between horizontal pieces of scantling attached to posts, the lower end of each hive being cut on a slant, and its bottom-board suspended at each corner by a wire hook, the idea being to facilitate the removal of litter of all kinds, and to prevent the bee-moth from gaining entrance. At the top was a surplus-honey chamber, about one-fourth the size of the brood-chamber, opening at the side, and furnished with two square surplus boxes, each having glass ends in front, and four communicating-holes through which the bees entered from below. These boxes held about ten pounds each of comb honey; and whenever a colony filled them during the season, it was considered a record or maximum yield.

As soon as old enough I began to take charge of the bees, and to study their habits. I bought and read the works of Quinby, Kidder, King, Langstroth, and others, and subscribed for the *American Bee Journal*, for which I became a frequent contributor in the early seventies. Quite recently I purchased a copy of Dr. Miller's "Forty Years Among the Bees," and was surprised to note that he gives me the credit of being one of his early teachers. In those days I thought I knew it about all; but a half-century has passed, and I am still learning.

Being fully convinced of the superiority of the Italian race of bees, I bought my first queen of father Langstroth, successfully introduced her, and kept her for several years. I closely read the exploits and achievements of "Novice," in the *Bee Journal*, and well remember the first issues of *GLEANINGS*. Yet bee-keeping was never my main business. For twenty-five years I was editor and publisher of *Seedtime and Harvest*, in which I maintained an apiarian department, conducted by James Heddon, yet gave most of my time and attention to growing and selling seed.

During the last ten years I have traveled quite extensively throughout the Union, and have visited many of the most noted bee-keepers. At the same time, at home I have kept more bees and produced much more honey than I ever did in my younger days.

WHY KEEP BEES?

First, because the honey-bee is one of the

cogs in the wonderful mechanism of nature, and is as necessary to the successful production of fruits as are the birds and showers. Nectar was placed in the flower by the great Designer to attract the bee, for the purpose of carrying the pollen from the stamens of one blossom to the pistils of another, in order to cross-fertilize them and render them fruitful. It is a mutual arrangement. The bee is for the flower as much as the flower is for the bee; and the very life and existence of many kinds of fruits, vegetables, and other plants, depend as much upon the bee as does the life of the bee upon the flowers. The bee-keeper is, therefore, a public benefactor.

Secondly, there is pleasure and profit in bee-keeping if conducted by modern methods; and as a hobby or diversion for business men I would place a few colonies of bees far in advance of chicken-raising or any other outdoor home industry.

I believe that there are few localities where many more bees could not be profitably kept; and the amount of honey that is continually going to waste all over this country, if known, would fairly astonish the world. Indeed, it could easily be proven that the honey-flows, as they come along from different sources, are far more abundant, yet perhaps shorter in duration, than most people suppose; and a knowledge of this fact, coupled with ability and proper facilities for caring for them at the proper time, constitutes the greatest factor of profit on the part of the up-to-date bee-keeper.

It is my purpose to show how to manage bees so as to secure the proper share of this great waste. In proof of the assertion just made, that in few if any localities are there bees enough to secure all the honey that nature so lavishly supplies, let me cite the case of Mr. E. W. Alexander, of Schoharie Co., New York, who, for several years before his death, kept an average of 750 colonies of bees in one yard, all on about one acre of land. By knowing the nature of his field, and about when to expect the honey-flows from different sources (buckwheat being his most important one), and by seeing that each colony was supplied with empty combs at the critical moment, when needed for storage, he succeeded in securing an average of over one hundred pounds of extracted honey per colony, the aggregate of which would amount to over 37 tons. Now, if it was possible for this great amount to be gathered from within the area of a circle covered by the flight of one bee, whatever distance that may have been, how much do you suppose may go to waste, for the want of bees to gather it, in thousands of other localities where not even one hundred pounds is secured and saved within an equal area? Are not the possibilities great enough to warrant a study of this subject, with a view to determining what may or may not be accomplished along this line in your lo-

cality, or in selecting some other locality where you may profit by the knowledge you may gain?

Why you should *not* keep bees may now be considered in order to ascertain whether the objections can match or overbalance my affirmative reasons. First, no doubt you will admit that a fear of stings is your greatest objection; and, secondly, perhaps you imagine that some large trees surrounding your premises should be selected by the bees as alighting-places, thus causing you too much trouble in hiving swarms. Let me assure you that both of these objections can be almost entirely overcome.

By the use of a little smoke, the crossnest and most irritable colony may be made gentle. A whiff of smoke blown into the hive frightens the inmates, and they at once proceed to fill themselves with honey. If there is no unsealed honey readily attainable, sprinkle them liberally with sweetened water, which they will take instead, and, like a man after dinner, they are invariably better-natured when filled than when empty. And then when obliged to open a hive, a pair of gloves and a bee-veil over the face will prevent your being made a target by some mischievous scout. Another curious fact is that, after you have been stung a few times, your system becomes inoculated to the poison, and you rarely observe any unpleasant effects, such as the closed eye that the tenderfoot may be likely to suffer.

In many localities there are not bees enough to fructify properly the blossoms of fruits and vegetables. Most bee-keepers now prefer to get their increase by artificial divisions rather than by natural swarming, as thus it may be done at one's option and convenience, and most of the risk of absconding swarms may be eliminated. It is only necessary to keep the wings of the queens clipped so they can not fly, and you will have the whole colony under perfect control. Should they attempt to swarm, you may make them literally hive themselves instead of alighting in some tall tree.

To accomplish this, as soon as they are in the air remove to a short distance the hive from which they issued, and place an empty one in its stead. You will find the old queen on the ground in front, vainly endeavoring to accompany them. Secure her in a cage and wait till the swarming bees have missed her. They will probably begin alighting in a cluster; but finding that not all is well with them they will soon proceed to return whence they came, and will thus be made to enter the new hive. Now liberate the queen at the entrance; see that she goes in with them; and as soon as all are in, move them to any desired situation, and place the old hive on its original stand.

When bees prepare to swarm they make provision for themselves for the journey by filling their bodies with honey; and when in that condition, as above stated, they may usually be handled with impunity. In early spring, when examining our colonies we clip the right wing of each queen if she

is not already clipped. The next year we clip the left wing, and the third year both wings. This marks their age up to three years, which is as long as or longer than it is usually profitable to keep them, and it prevents the possibility of swarms absconding to the woods.

WHERE BEES MAY BE PROFITABLY KEPT.

There are few locations where bees may not be kept either in country, village, or city, as they will go three or four miles if necessary for food. In the writer's locality they start in early spring on the maples, the soft and hard varieties following in succession, and lasting two or three weeks. Then follow dandelion, fruit-blossoms, red and black raspberries, locust, white clover, basswood, sumach, milkweed, catnip, Canada thistle, goldenrod, buckwheat, wild aster, and a score of wild flowers whose names are not familiar, thus covering the season. During the height of flow from each of these sources the secretion of nectar is very abundant but of short duration. To secure it, the flower must be visited many times in a day, and an immense number of bees are required to keep it from evaporating and going to waste.

Yet while it is true that in only a few localities are there bees enough to secure and save more than a fraction of what nature so bountifully supplies while these flows are on, there are often long intervals between when there is little or none to be had, so I believe it would pay most bee-keepers to consider whether nature may not be aided by planting something which will fill up these interstices and keep the bees more constantly employed, and, at the same time, produce a crop which will pay its cost besides the honey.

For this purpose I would recommend buckwheat, raspberries, alsike clover, mustard, and rape, for this section. Melilotus, or sweet clover, where it has started, reseeds itself and spreads naturally, and is, without doubt, one of the very best honey-producing plants known.

The chief value of sweet clover as a honey-plant comes from its habit of long duration of bloom, so it is sure to bridge over the gaps left in the succession between many other plants named. It is a great soil-improver, and it has been found that it prepares the way for alfalfa by inoculating the soil with the bacteria necessary for its growth. On this account the demand for its seed is increasing, which will no doubt make it a paying crop without considering its value as a honey-producer.

HOW TO PROVIDE PLENTY OF ROOM AND PREVENT NATURAL SWARMING.

The most important secret in bee-keeping is to see that strong colonies are well supplied with empty combs, so that the bees may store quickly while the abundant flow lasts. This is accomplished by the following process:

As early in spring as we can get the queen to fill the hive with brood we remove all the combs but one, on which the queen must be

left, and put in their places either empty combs or frames of comb foundation. Then we put on a queen-excluding honey-board, and above it another body, uniform in size, in which all the removed combs, together with the brood and adhering bees, are placed. A $\frac{3}{4}$ -inch entrance and exit hole should be made in the upper part; for as fast as these combs become empty by hatching brood, the bees will proceed to fill them with honey, and they soon learn to use this upper entrance and save much time by its use. Besides, it gives ventilation and allows the expulsion of drones, which otherwise might clog the excluder, and smother the inmates of the upper story.

The queen being confined to the lower story she has plenty of room to go on with her egg-laying, and she will soon have it filled with brood, thus making faster increase in numbers and strength than otherwise would have been possible, and the increased room given just at this time will usually dispel any intention or tendency to swarm.

The main advantage given by this system lies in the fact that the bees will invariably proceed to store quicker and more abundantly in this upper story than they can be induced to do in supers of sections arranged for comb honey. But in this case, of course, this honey must be removed by extracting, and this explains why much more extracted honey may be produced than sections of comb honey.

This also affords an excellent opportunity to produce some young queens. When the division is made, place over the excluder, for twenty-four hours, a complete cut-off, consisting of a sheet of wire netting, or even a cloth or heavy paper. This renders the bees above actually queenless for this short period, which causes them to start queen-cells freely, which they will continue to care for after the cut-off is removed, and these may be cut out and caged, or given to other colonies or to nuclei on the tenth day, and without any loss of time on the part of the bees or breeding queen.

Do this only with the best breeders, and put a nice sealed cell in a cell-protector, in place of the black, hybrid, or old and questionable queens, and you will requeen with as little expense and waste of time as is possible. These young queens are always accepted whenever they hatch within a hive, and you are saved the trouble and risk of introducing queens. Then, even if some of these should mate with black drones, if bred from a pure-blooded mother their drone progeny will be pure next year, when the operation may be repeated with chances of mismating greatly diminished. Young vigorous queens, raised from selected mothers, are a strong factor to success in bee-keeping.

The process described above has also proved with us a complete cure for European foul brood, the infected combs being cleaned out and filled with honey, and the queen compelled to use only new clean combs for brood purposes.

Factoryville, Pa.

THE SWARMING IMPULSE NOT CAUSED BY ANY ONE CONDITION.

BY R. F. HOLTERMANN.

In my estimation the swarming problem will not have much light thrown on it by efforts to confine the causes under one head. I have no doubt that the control of swarming, or, rather, the prevention of the desire for swarming, in powerful colonies, without reducing the numerical strength, either at the moment of or during the future of the honey-flow, is the capstone of successful bee-keeping.

The successful solution of this problem makes it possible to keep more colonies, to have them scattered, to take a honey crop with less labor and anxiety, and to get a larger surplus crop (if there is a surplus) than can be obtained through swarming. From this I except a tropical country with a honey-flow the year round; but I do not except in our own country an average year with a light and dark honey-flow no further apart than clover and buckwheat. In many localities keeping down swarming makes possible more successful and uniform wintering as well as, in some seasons, the difference between a honey crop and a failure.

VARIETIES OF BEES.

With the black or German bees, Italians, Carniolan, Cyprians, and Holy Land bees there is a marked difference as to disposition to swarm (I will not include Caucasians, as I am acquainted with them only by hearsay and sight. I can not find that they have any superiority over Carniolans. Even a breeder of Caucasians privately advised me to stick to the Carniolans). Of all the varieties mentioned, the Holy Land and Cyprian bees are the most prone to swarm. I know of what I write, for I spent two years with D. A. Jones, of Beeton, Ontario, when these bees were first imported into America. The Italians, as a variety, are, perhaps, on the whole the least inclined to swarm. But the bees the least apt to swarm are not necessarily the best for the bee-keeper who can control swarming.

CONTRACTED ROOM.

My first attempt to keep Carniolan bees was an overwhelming failure. It was in the days of eight-frame Langstroth hives, and with the contraction of the brood-chamber for comb honey, which is something Carniolans will not stand, I found that it was useless to attempt to keep these bees for profit under such conditions.

SMALL ENTRANCES.

I have had a colony of Carniolan bees swarm when they had only about half filled a twelve-frame Langstroth brood-chamber having eight combs, and two of these yet empty, and they were headed by a previous autumn's Carniolan queen. A careful study of the conditions did not reveal supersedure nor any thing else, except that we had hot weather while the bees were packed, and they had a very small entrance on account of the fact that the colony had been only a

nucleus the preceding fall. By dear experience I have learned that Carniolan stocks are exceedingly liable to get the swarming impulse during fruit bloom if they do not get plenty of ventilation; and in the past some of my Carniolans have had the swarming impulse before I thought they were really crowded enough to need supers and large entrances, especially in view of the future break in the flow. Italians, hybrids, and blacks, equally strong, did not get the swarming impulse under like conditions. Excess of nurse bees could not be the cause of swarming at this time, for it would be unreasonable to suppose that one colony has any more young bees in proportion to brood than the other. In fact, during the building-up process the proportion of brood to bees is on the increase; and with a good Carniolan queen there is all the brood the bees can look after.

WHEN THE DANGER.

My experience fully supports the following: The time for the greatest danger of swarming with strong colonies is during the light honey-flows before the heavy surplus flow sets in, and during idle time between heavier flows.

When the bees are about ready for super room is a most critical time. I put supers on the hives too early rather than too late; and as I generally keep the bees packed in their winter cases until the clover begins to yield nectar I run no danger of chilling brood.

If during a good honey-flow the bees enter the supers with a rush, I find but little trouble, under right management, until the super room begins to be crowded *for the process of ripening* the stores they gather from day to day. I do not recollect ever having a twelve-frame Langstroth hive with three, four, or five supers on top of it wanting to swarm. We are told that in tropical countries during the heavy flow the bees abandon swarming; and when the light flow follows they get the swarming impulse. I believe it is much the same under proper management in more northerly localities.

The trouble does not lie solely in the lack of super room. Neither is it a lack of ventilation alone, nor in hive conditions alone, as then all the varieties of bees and all colonies would swarm under certain conditions. This much is plain—that, within recent years, there are those who have learned so to manage that the bees will bend their energies in the direction of gathering honey rather than in swarming.

Brantford, Ont., Can.

DISTURBING BEES DURING WINTER.

Was it a Costly Mistake?

BY G. T. WILLIS.

Robert B. Mc'ain, Nov. 15, page 685, says regarding the advisability of opening hives in the winter time in order to ascertain the condition of the food supply, "The proba-

bility is that the bees will be injured rather than helped by disturbing their household affairs." Now let me emphasize this to the inexperienced bee-keepers. Don't allow yourself to be so overcome with curiosity that you can't leave the bees alone. If you do, you will never forget it. Josh Billings, the pithy writer of years ago, uttered this wise and truthful sentence: "Experience teaches a good school, but the tuition is rather high." Well, I have attended that school myself, and I paid the tuition in full. For fear that some one may be tempted to commit a similar blunder I will give my experience of twenty-seven years ago.

In the fall of 1884 my 38 colonies, in ten-frame hives of my own make, were all in fine condition for winter, as there were plenty of bees and stores. The hives were so made that there was permanent packing at each end; and when preparing them for winter I took out two or three frames and put a follower on each side and packed with straw, both at the sides and on top of the frames, which I considered an ideal condition for wintering. Old residents remember that, during the winter of 1884, an unusual amount of snow fell, and it was cold from the second week in September till the last of March, so that the bees were buried under the snow most of the time. As I was engaged in the work of the ministry I was away from home much of the winter; but on returning the last of February I remained a few days. The 28th of February being a bright and warm day I did the very foolish thing of opening hives containing those 38 colonies to satisfy my anxiety as to whether they had stores sufficient to last them until spring. Now for the sad experience that cost me so dearly. When I returned and examined them early in April, I had only seven colonies left. I have never, in the twenty-seven years since, allowed myself to be tempted to inspect a colony in winter.

I may have something to say at some future time as to how I succeeded the following season in retrieving my loss.

Hoopeston, Ill.

[We believe our correspondent is wrong in supposing that the opening-up of his hives on the 28th of February, a "bright and warm day," was the cause of the heavy mortality among his bees. While it is certainly bad policy to open up outdoor colonies on cold days, causing the clusters to expand beyond the point where they can keep warm, it seldom does any harm when the air is warm enough so the bees can fly. If, however, the colonies have been well supplied with stores during the previous fall, it is advisable for beginners, at least, to let the bees entirely alone. However, if there is any doubt about the amount of stores, we recommend opening up the hives when the weather is warm enough so the bees can fly, and then put rock candy or a comb of sealed stores on top of the frames after very gently lifting the cover and the packing, and replacing the same.—Ed.]

EXAMINING A COLONY OF BEES.

BY F. DUNDAS TODD.

[However familiar the experienced bee-keeper may be with the details as told in this article, we feel sure that the points mentioned will prove of interest and value to the beginner, for whose benefit they were especially intended.—ED.]

It is always good policy for the beginner in bee-keeping to see an experienced hand manipulate the frames of a hive before he tackles the job himself, because it will give him confidence, helping to overcome the instinctive dread of stings. He will learn by observation that, when handled skillfully (and this word in the present connection really means *gently*), most bees remain quietly on the frames, and are no more dangerous than so many flies. Worker bees are constituted of high nervous tension, and will not tolerate with equanimity a sudden jar or shock of any kind; therefore all movements must be easy and gentle if one desires them to be in good humor. In his dread of stings the novice is apt to rush things and be jerky in his movements, and so bring about the very condition he least desires—an irritated, pugnacious community. It is not wise to depend upon smoke to quell an insurrection. The true rulership consists in avoiding the beginning of strife.

Here are a few simple rules that are worth following while working with bees:

1. Never stand in front of the hive entrance, for that is the bee's roadway. You will soon get notice to move; and if you fail to comply, stinging will be attempted.

2. Never put a frame nor any other part of a hive in front of the entrance.

3. Leave all frames in the same order in the hive as you found them, and turned the same way.

4. Make every movement slowly and deliberately, never dropping a frame into position, but placing it exactly where it belongs.

5. Avoid, if possible, killing a single bee; for among communists, whether human or not, an injury to one is an injury to all, and must be avenged. Kentucky feuds are a lingering remnant of the Scotch clan spirit among the descendants of the Highland exiles of the eighteenth century.

It is possible you do not have a neighbor to give you the first lesson, so I will invite you to come to my yard and examine with me a hive; and since you can not be with me in reality I will bring my camera into play and illustrate each feature that may be worthy of notice.

First, we get the smoker agoing, then put on our bee-suits. All being ready we stand alongside the hive, which will appear as in Fig. 1—that is, if it is an eight-frame Langstroth, which this happens to be. Its cover is rather different in design from those in general use; but it is popular on this side of the Pacific coast where we have long-continued winter rains, and only short spells of severely cold weather. Notice that the bee-keeper is standing on the sunny side of the

hive so that, when he comes to examine the frames closely, the sunlight will strike into the cells.

We will begin by removing the cover, see Fig. 2; and when we do so we find a piece of cloth underneath. This is known as the quilt, and is usually made of table oil-cloth with the glossy side down, as the bees have a habit of carrying out any fabric they can tear to pieces. The purpose of this cloth is to retain the heat of the hive, for reasons that will be seen later.

The cover of your hive is probably a flat one; and when you try to take it off you may find it fastened down tight. Very likely the bees have cemented it all round to the body with propolis—a kind of glue—and we must break the bond. So we force the hive-tool under one corner of the cover and give it a twist; or, press your left hand firmly upon the center of the cover, and at the same time pull up one corner with the right.

The cover is set to one side; then we take the quilt by one corner and peel it off. We now see the tops of the frames, from between which, if it be late spring or summer, thousands of bees are appearing and covering the upper part. Fig. 3 shows how the hive will look at this stage.

Bees are much like people. Some are good-tempered and some are not. Any one keeping bees as a hobby is foolish to have any of the vicious kind, more especially if he is surrounded by near neighbors. The best working bees in my own yard are so gentle that I rarely have to use smoke on them. But I have had colonies so vicious that they attacked any living thing coming within ten yards. The queens at the head of these colonies soon ceased to exist, being replaced by others from a less pugnacious strain. So when we remove the quilt we have a chance to learn something about the temper of the insects in this particular hive; for if they are good they will stay quietly on the combs; but if bad they will run around and fly off—some at us, and some to the hive entrance. Now is the time to use smoke to keep them in subjection. How much, will depend on circumstances; but never more than is necessary. With the average hive it is usually enough to give a few puffs across the frames, never down through them, as the quilt is being peeled off. In the case of a colony known to be irritable, it is usually necessary to give a puff or two into the hive-entrance before removing the cover. In spring and autumn, when the colonies are weak in numbers, it is often unnecessary to use smoke.

In the eight-frame hive we are examining, the inside width is 12½ inches; but the frames occupy only 11 inches of that, so there is a free space of over one inch on one side of the frames. Part of this is filled by a "follower" made of a thin board. Occasionally this is called a division-board. In use it is pushed tight against the last frame.

Our first work is to remove the follower that occupies the space between the frames

and the side of the hive. Very probably it will be glued to the frames with propolis, so we insert the hive-tool between the frame and follower, pushing aside the bees gently if in the way; then with easy pressure we pry the board apart from the frame, first at one end then at the other. The follower is now removed from the hive and set to one side, or at the end of the hive. We can now reach the first frame, which is apt to be clear of bees, excepting from May to September. As before, we break the glue adhesion with the hive-tool, then lift the frame with both hands, one at each end-bar. Should bees be clustered where fingers will grasp the top-bar, gently puff a little smoke on them and they will quickly scurry away. Remember, it is little tricks like these that make hive manipulation easy and prevent the bees becoming ill-tempered. Lift the frame straight up, with your back to the sun, and proceed to examine it. Fig. 4 shows the operation. (The editor will, perhaps, permit me to explain here for the benefit of Dr. Miller, who may in this and following illustrations see a chance to catch hold of my short hair, that in making these photographs I had to choose be-

FIG. 1. — Ready to begin work at hive No. 1.

FIG. 2.—Removing the cover.

tween good photography and good bee-keeping. The former called for lighting, as is shown in the preceding pictures; but I felt that, with the others, the lighting ought to be in harmony with the instruction that was being given. Even after this explanation I feel the good doctor will trip me up.)

The inside of the frame, we find, is filled with wax comb, which is made up of a great number of cells—at least 3000 on each side. In these cells is stored the food supply of the colony. In them are laid the eggs from which develop the young bees, the whole time from infancy to maturity being spent in such narrow confines. Then in the cold days of winter, when all activity in the hive practically ceases, when the individual members huddle close together to keep each other warm, each empty cell may be filled with an insect, so that no space shall be unoccupied. The interior of a hive is a wonderful utilization of a limited area, down to the minutest detail; and it is hard for most people to realize that, in a capacity of about two cubic feet, as many as 50,000 bees will carry on all

the activities of their life, for here is at once a pantry, kitchen, incubator, nursery, living-room, and bedroom for them all.

But let us investigate our comb a little more. First we shall probably notice that there are at least two different sizes of cells—one series in the upper part of the frame, running about five to the inch; another kind, generally in the lower half of the comb, that are a little larger, running about four to the inch. In the smaller cells the worker bees are raised; in the larger ones the drones, which are the males, spend their days of infancy. Both kinds of cells are used when necessary as storage for food. In a well-managed hive the worker cells vastly predominate; in fact, all good bee-keepers strive to keep the drone-cells to the lowest possible number. Drones are essential to the welfare of the apiary; but an unlimited quantity of them means a waste of valuable space and food, for they are consumers only. Fig. 5 shows the two kinds of cells side by side.

We will now proceed to examine the next frame; but first we will dispose of this one by setting it on the ground, leaning it against the side of the hive. As before, we will break the gluing between the frames. Since it is May it is probable the colony is strong enough to cover six frames, so that this one may have thousands of bees on both sides, while the weight suggests that the cells contain something. They do, for the center of the comb is filled with young bees in all stages—eggs, larvæ, and sealed brood. These are surrounded by a band of

FIG. 4.—Lifting out the first comb.

pollen, about an inch or two wide, while outside of that, especially at the top and ends, is honey—quite a neat arrangement, you see, so as to have every thing handy—nursery in the center, with the food all round about. But, stop a minute. All the other frames are arranged exactly the same way; so think a little, and you will realize that the brood-nest is a ball, with, of course, the most brood in the center frame, the least at the sides. Now you will understand why you should not disturb the order of the frames when you examine a hive, as changing the arrangement will upset the brood-nest. If you never set more than one frame outside of the hive you will avoid the chance of misplacing the frames.

SHAKING BEES OFF THE COMBS.

May be the comb is so thickly covered with bees that careful inspection is impossible, in which case hold the frame above the hive; raise it slowly about a foot, then lower it quickly, finishing up with a sudden jerk, when practically every insect will drop on the frames below.

Fig. 6 shows the position of the frame at the end of the operation. It is not considered wise to shake the queen off the combs at the season when she is laying heavily. Another way, which I prefer, is to hold the frame perpendicularly by the end of the top-bar with the left hand, then with the right hand clenched hit the left a smart blow from above (Fig. 7). The comb being free from bees, turn your back to the sun

FIG. 3.—The quilt removed.

FIG. 5.—Worker and drone cells side by side, showing the difference in size. The former measure five to the inch, while the latter run four to the inch.

so that its rays may shine into the cells. Along the upper part of the frame, and at the ends, the cells will probably be all sealed, the cappings (as the coverings of the cells are called) being flat, or often slightly sunken, and wrinkled, and generally semitransparent. Such sealing indicates the presence of honey. On the edge of this region there will likely be a narrow belt of unsealed cells showing the honey, indicating that the bees are using up their stores to feed the young. When we reach the bottom-board in our investigations we shall find lying there a brownish-looking deposit, like coarse dust, but which is really the fragments of comb-capping torn from the cells.

POLLEN STORES.

Next to the open cells with honey often comes a narrow band of cells filled with a brownish-colored solid substance. This is pollen, or bee-bread, which is the male element of plants, and forms part of the food of the young of the bee while in the larval or maggot stage.

THE BROOD-CELLS.

In the center of the frame we find the brood in all stages—eggs, larvæ, and cocoons. The last are sealed over, just as is the honey, with this difference, however, that the cappings are dark-colored, and slightly raised in the case of worker brood—decidedly so with drone-cells. The larvæ are easily seen, coiled up in the bottom of

FIG. 6.—Comb cleared of bees for inspection.

FIG. 7.—The best way to jar the bees from the comb

Figs. 8, 9, 10.—Various positions of holding a comb, showing the manner of turning it in such a way that it is always supported, thus avoiding the danger of a heavy comb dropping out of the frame.

the cell, especially after they are three days old; but the eggs are harder to distinguish on account of their small size; in fact, they look like very short bits of white thread attached to the far end—that is, the bottom of the cell. It is just as well for the beginner to learn to detect the presence of eggs in the comb, for an evenly arranged patch is pretty good proof that the queen has been busy.

HOW TO REVERSE A COMB.

A frame has two sides, so you had better look at the other one too. Your most natural impulse will be to cant the frame over; but don't do so; for as you tilt it up to the level the weight of the comb is apt to break it away. Try it thus: Lower one hand, say the right, until the top-bar is perpendicular (Fig. 8); turn the frame half way round, using the top-bar as a pivot (Fig. 9); then raise the hand that was lowered (Fig. 10). Your frame is now upside down, with the second side toward you. Here is another method that can be carried out without a pause: Let the lugs of the frame rest on the middle fingers of each hand, these being bent toward the chest. Turn the comb end for end by swinging the left hand to the right of the right hand, then swing the comb up into the position shown in Fig. 10. To get to the original position, reverse the movements.

REPLACING FRAMES.

When through with this frame, replace it in the hive, pushing it tight against the vacant side. There is no excuse for placing it on the ground. If you have changed it so that you have forgotten which is the front end, just look at the brood, for the bees prefer to have their young toward the entrance of the hive, but the honey at the rear. When you have examined as many frames as you want, push them over to their original position by putting the hive-tool between the side of the hive and the end-bar of the frame, and using it as a lever. Now insert the frame first taken out, pushing it into place, then the follower.

Occasionally it is necessary to move a brood-chamber from the stand, and to the novice it is a problem what to do with it. He feels he should not set it on the ground, as there is every chance of killing many bees. The smaller the bearing surface the better, so one can use a bottom-board, an empty hive, or a very shallow box, resting the bottom of the hive across the sides.

Our first excursion through a bee-hive has been quite a long one, and has disturbed the

arrangements of the inmates, not only to a considerable extent, but possibly to the injury of the young; for in May it is a rather extensive incubator where many thousand eggs are being hatched while young bees are being brooded. An open hive means the loss of heat; therefore we resolve that in future we will do the necessary examinations as speedily as possible, and never lift the cover unless the shade temperature is about 65 or warmer.

Victoria, B. C.

THE BRAULA CCECA NOT A TRUE PARASITE.

BY JOHN A. WOLFFSOHN.

I notice in your August 15th issue, page 468, an interesting paper on "*Braula cœca*," by Dr. Bruennich, in which the author says that "to my knowledge no one has observed the act [of feeding of the bee-louse] till now." It may interest the doctor and some

Apiary of T. H. Hill, Maywood, Ill., a suburb of Chicago, Ill. A neighbor's house is just back of the fence, but there have never been any complaints. The hives are at the back of the lot in full view of the street, and attract a great deal of attention, especially when the owner is working with the bees.

of your readers to learn that M. Lucien Ichès, in his excellent work, "*L'abeille domestique*," Paris, 1905, quotes the following from J. Pérez, *Notes d'apiculture*:

One day, having captured a bee with one of these lice I fixed its head with a pair of pincers sufficiently to keep it unmovable, and to capture the small parasite easily. Both it and the bee were left for a while on the table in my studio, under a glass.

When I returned to them I was not a little puzzled to see the parasite in the most vivacious and strange agitation. Seated on the fore part of the bee's head it was moving about with incredible vivacity, as though possessed of veritable rage. Now it would go to the margin of the bee's cap, with its fore feet raised, stamp and scratch as hard as its weakness would allow at the base of the bee's lip; then it would suddenly run back to the insertion of the antennæ to renew its impetuous attack immediately. I was quite taken up by my first surprise, when I suddenly saw all this fury turn to per-

"Nailing" together GLEANINGS for half a year.

fect calmness, and the little animal squatted on the edge of the cap and bent down its head to the bee's mouth, which was slightly trembling, and sucked up a drop of moisture.

I instantly understood. The movements I had just witnessed were preparatory to the animal's meals. When the louse wishes to feed it goes to the bee's mouth, where the motions of its feet, armed with bent claws, produce a tickling sensation, perhaps disagreeable to its host, but at least provoking some movement of the bucal organs, which slightly open and release a small drop of honey which the louse at once licks up.

Thus the *Brachia caeca* is not a real parasite of the bee in the true sense of the word. It is rather a guest—queer, if you like thus to consider it, like so many others existing among animals.

Valparaiso, Chili.

BINDING COPIES OF GLEANINGS CHEAPLY.

BY C. A. KINSEY.

Take the copies of GLEANINGS from July 1 to Jan. 1, 12 in all. That is enough to be convenient. Place them in order in a clamp or vise and fasten firmly. Drive three shingle nails along the back on each side. It is not necessary that the nails go clear through if they are driven in from both sides. Then take them to a printing-office if convenient, and have them trimmed. Cover can be added if desired. This way will keep them firmly together, and with the yearly index at the back it will take only a few moments to find any article desired.

GASOLINE-CANS FOR HONEY.

Can you inform me if it is safe to use gasoline-cans to put extracted honey in—that is, if there will be any substance from the gasoline that can't be washed out that would taste in the honey?

I can get a considerable number of such cans, all new and in good condition, for nothing, that could be used to store my honey in, or for local trade.

Belgrade, Mont.

[We do not believe there would be any objection at all to gasoline-cans provided they are clean and free from rust. Kerosene-cans can seldom be cleaned so that all the odor of kerosene is removed, and the honey is then tainted; but if you can be sure that the cans you refer to have never been used for kerosene, but only for gasoline, we do not think there will be any difficulty at all. They would have to be rinsed out, of course; for after a can is emptied of gasoline there is some dirt and sediment that remain, usually; but this could be easily washed out.—ED.]

AN OKLAHOMA EXHIBIT.

Some Proof that Oklahoma is Advancing as a Honey State.

BY N. FRED GARDINER.

Photography has become a wonderful art. It can reproduce on a flat surface, in black and white, marvelous shades of beauty, and in many instances bring to our attention details that escape the eye in actual observation of the original object. But photography falls far short of doing justice to a honey exhibit. It seems that the eye of the camera can not penetrate the glass jar and show up the rich tint and the delicate structure of the honey and the comb.

Therefore we can judge of the relative merit of an exhibit only by comparison.

I did not realize how true this is till I saw the photograph which is reproduced with this article. This is undoubtedly a good photograph, comparatively, but it certainly fails to bring out the beauty of the exhibit. It is a picture of the exhibit of B. F. Bartholomew and wife, of Norman, Oklahoma, at the State Fair, Oklahoma City, 1911. This display covered a space of 10×30 feet, and was a fine example of the bee-keeper's art. There were two other exhibits that would compare favorably with those of other State fairs, but the one shown here took 14 out of 16 blue ribbons, and was, therefore, clearly in the lead.

Mr. Bartholomew made his plans as would an architect—measured his space, then built his special shelving at home and shipped it, together with the jars which he had ordered especially for each space, to the fair.

The designs in honey and wax were especially meritorious, the design in honey being built from foundation in the letters sawed in the boards, and mounted under glass. The designs in beeswax, were the horse-shoe and shield, and were of solid wax, and not dipped. This is another place where the camera fails to give results. The lettering on the shield and the wreath on both are not brought out. These were all hand carved from different shades of wax, and made a most pleasing effect. To the right can be seen just the corner of a fireplace built of solid wax brick, and holding a wax kettle, etc. Mrs. Bartholomew shared equally with her husband in arranging this display. The honey was mostly from alfalfa and sweet clover. This exhibit shows that Oklahoma is already prepared to compete with many of the older States.

Geary, Okla.

SOME PRACTICAL EXPERIENCE WITH A STEAM HONEY-KNIFE.

How it Assists in Extracting and Uncapping when the Honey is Cold.

BY B. M. CARAWAY.

Some time ago the editor asked for reports, favorable or otherwise, concerning the steam honey-knife. There has already been a good deal said about this knife; but I don't feel that it has been given proper credit in spite of all that has been said. It is certainly a wonderful labor-saver.

One of the best features about this knife, and one that has not been mentioned, is that, when the honey is a little cold, the hot blade heats it up so that the extractor will throw it out of the cells easily. Quite often during the extracting season I take off honey one day and extract what I can; but there may be some left over until the next day. During the night it cools off until it is very thick. When I uncap it with the steam knife, however, it warms it up again until it extracts just as quickly as honey just removed from the hive that contains the original heat from the bees.

With the steam knife I can uncap faster than any one can using a cold knife. I have tried nearly all the knives on the market, including a butcher-knife, but none of them can be compared with the steam knife. There have been several large producers here, among them Mr. W. H. Laws, of Beeville, Texas, and all of them have been quite carried away with it. Mr. Laws is the owner of more bees than any other man in Texas, probably, and he said it was the best thing he had seen for a long time. If one uncaps with the downward stroke, the weight of the knife will slice the cap-

Exhibit of B. F. Bartholomew at the Oklahoma State Fair.

Lewis' ornamental observatory hive.

pings off one side. Of course, the knife alone will not go down as fast as though it were pushed a little, but still it does good work. In fact, while it will not do all my uncapping entirely by itself, it makes the work much more pleasant.

The worst trouble that I have had is that I have to wait a few minutes for the steam to be generated; but I find plenty to do in this time, as I have the cases to open and the tops of the pails to pry out, so that, before I get ready, the water is boiling hot and the knife ready for use. On page 272, May 1, Mr. O. B. Metcalfe says that he has trouble in generating steam enough, and he finds some kind of boiler having flues necessary. I have never had this difficulty; but it may be that the honey has a great deal to do with it. On one occasion I had

the stove turned up too high; and the can, in which I was generating the steam, burned. I use a one-burner gasoline-stove and a five-gallon can for the boiler, and I have never yet failed in having all the steam I wanted. I put in about a gallon and a half of water.

On page 451, August 1, Mr. Crane says that, while the steam knife works finely, it leaves a thin scum of wax over the cells; and when the honey comes from the extractor, this thin scum will go right through the strainer and then rise to the top of the honey in the can. I have never had any such trouble as this, although I have extracted several thousand pounds this year, all of which was uncapped with a steam knife.

The heat from the stove does not bother

The inside has the same dimensions as an ordinary ten-frame hive, and the sides are of glass.

me, for I have a fan run by a belt from a pulley on the engine. The fan was too much of a good thing at first, for it kept blowing out the blaze; but I remedied this by making a shield of a board in front of the stove, so that I have had no trouble since.

The great advantage of the steam knife is that one does not have to stop to scrape the cappings off the blade. The metal is so hot that they slide off as fast as they get on, and it is just here that the hot knife saves a great deal of time. Some have objected to the steam hose or tube, but I have never found it awkward in the least. In a very few minutes one becomes accustomed to it. Mathis, Texas.

[There can be no question but that on some honeys the steam-knife is greatly superior to the cold knife or one dipped intermittently in hot water. The steam-knife keeps hot every minute of the time, and, as Mr. Caraway says, it warms the honey and makes it unnecessary for one to keep scraping it on something to remove the excess of cappings.—Ed.]

BEE-KEEPING A RECREATIVE PURSUIT FOR A PROFESSIONAL MAN.

BY REV. J. M. LEWIS.

I wonder every suburbanite who has a garden does not have at least one colony of bees. They seem to me to be safe to keep, and perfectly harmless if treated with kindness and due consideration.

I have several colonies which are within ten feet of the house, and about thirty feet from the road where teams and automobiles are passing almost continually, and they have been there for more than five years, and have troubled no one.

I am sending some photographs of an ornamental hive which stands in the center of my flower-garden, the home of a fine colony of golden Italians. Scores of people—men, women, and children, have visited my garden this season, and not a person has received a sting. I have repeatedly opened the hive and removed the frames with the bees clustered on the combs to show my friends what can be done with bees.

I never use any protection in working among my bees, and but very little smoke; and sometimes I do not use the smoker at all.

The ornamental hive shown in the pictures is a fine advertisement, as it attracts the attention of people passing by. It is a double-wall hive. The inside is a standard ten-frame hive, and takes two supers. The brood-chamber has glass sides and back, and glass in the top cover, which I use when no supers are on. The foundation on which it stands is made of stones of different formations gathered from near and far, laid in Portland cement.

There are many ways in which an ornamental hive can be made, and yet be practical and an ornament, as well as a benefit to a flower or vegetable garden and to the

fruit-trees, of which almost every garden has at least a few, and will attract more attention than a rare plant or exquisite flower.

North Westport, Mass.

THE DISCOVERY OF THE SECRET OF FLOWERS.

A Brief Sketch of the Work of Sprengel and Mueller.

BY JOHN H. LOVELL.

The human race has long assumed (being the only organism at liberty to take itself at its own valuation) that it occupies a position of fictitious importance in the universe. It was a current maxim in the Middle Ages that man was the measure of all things. The world and its inhabitants, so ran this pleasant myth, was created a few thousand years ago solely to provide him with a congenial place of abode; and, because of his paramount importance, was placed in the center of the heavens. Not a little ingenious (and to-day amusing) speculation, was expended in an effort to explain how natural cataclasms and noxious animals and plants were disguised blessings; but that such was the fact, no doubt was permitted to exist. From these modest pretensions we have been receding for some centuries with much hesitation and reluctance. Perhaps the close of another hundred years will see them abandoned altogether, and humanity willing to admit that it is a part of nature, not outside and above her.

So long as these teachings prevailed it was very naturally a popular notion that the bright colors of flowers were of no importance except as they gave human pleasure. Much superfluous pity was wasted on those blossoms which, to use the words of the poet Gray, blushed unseen and wasted their sweetness on the desert air. Only a few years ago a similar sentiment was expressed by the editor of one of our popular magazines: "There was apparently no particular reason why the earth, at the time of Adam, should have been literally strewn with blossoms. They were of no particular use; there was only one man to see them."

This same idea is again repeated in Emerson's beautiful lines—

THE RHODORA.

In May, when sea-winds pierced our solitudes
I found the fresh rhodora in the woods.
Spreading its leafless blooms in a damp nook
To please the desert and the sluggish brook:
The purple petals, fallen in the pool,
Made the black waters with their beauty gay;
Here might the red-bird come his plumes to cool,
And court the flower that cheapens his array.
Rhodora! if the sages ask thee why
This charm is wasted on the marsh and sky,
Dear, tell them that, if eyes were made for seeing,
Then beauty is its own excuse for being.

It would seem never to have occurred to poet, editor, or philosopher that the beautiful hues of flowers might be useful to the plants producing them.

It was a German pastor, Christian Conrad Sprengel, at the close of the 18th century, who first pointed out the true signifi-

cance of conspicuous flowers. His book, now a botanical classic, attracted but little attention; his publisher did not even send him a copy of it, and in discouragement he did not publish the second volume, but turned from the study of plants to that of languages. The title of the work, "The Secret of Nature in the Form and Fertilization of Flowers Discovered," affords us the pleasure of knowing that he rightly estimated the importance of his observations. Sprengel clearly states, as is now well established, that the bright hues of flowers serve as signals to attract the attention of nectar-loving insects flying near by. He was led to this conclusion very fitly by the study of *Myosotis*, or the forget-me-not. He has not been forgotten. His name and theory were rescued from obscurity by Darwin; his book a few years ago was republished at Leipsic, and is now universally recognized, says Mueller, as having "struck out a new path in botanical science."

Sprengel was convinced that the wise Framer of nature had not produced a single hair without a definite purpose, and he examined a great many flowers for the purpose of learning the meaning of their forms and the arrangement of their parts. The salver-formed flower of the forget-me-not is sky-blue with a yellow eye. "While studying the flower of *myosotis* I was struck," he says, "by the yellow ring which surrounds the opening of the corolla tube, and which is beautifully conspicuous against the sky-blue color of the limb. Might not, I thought, this circumstance also have some reference to insects? Might not Nature have specially colored this ring, to the end that it might show insects the way to the nectar-reservoir? "On further observation he found that the entrances to many other flowers were marked with spots, lines, and dots differently colored from the rest of the corolla. These markings he called "nectar-guides." "If the particular color of one part of a flower," he rightly inferred, "serves to enable an insect which has settled on the flower easily to find the right way to the nectar, then the general color of the corolla is serviceable in rendering the flowers provided with it conspicuous even from afar to the eyes of insects that hover around in the air in search of food."

Sprengel decided that flowers secrete nectar for the sake of attracting insects, and that it is protected by hairs or nectaries in order that they may enjoy it pure and unspoiled. At first he thought that the flowers receive no service in return; but he soon observed that the guests pollinated the flowers. He even noticed the frequent occurrence of cross-pollination, and remarks that "it seems that Nature is unwilling that any flower should be fertilized by its own pollen." He described the manner in which some 500 flowers were pollinated; but as he knew little about insects he did not pay much attention to the different kinds of visitors.

But while Sprengel had learned the secret

of flowers, and knew that their colors, odors, and forms were not useless characters, he failed to discover why cross-pollination is beneficial; and this omission, as Mueller has remarked, was for several generations fatal to his work. In 1841, Robert Brown, an eccentric English botanist of great learning, advised Darwin to read Sprengel's book. "It may be doubted," says Francis Darwin, "whether Robert Brown ever planted a more beautiful seed than putting such a book into such hands." Thus is the torch of learning, shining with ever increasing effulgence, handed on from one investigator to another. Darwin was already engaged in studying British orchids, of which he wrote to Bentham, "They are wonderful creatures, these orchids." His interest in the structure and pollination of these curious plants was greatly increased by reading what the old German pastor had done. Darwin soon discovered that frequent crosses increase both the vigor and productiveness of the stock, and that an occasional cross is indispensable. The principal agents which nature employs for this purpose are insects, birds, wind, and water. So impressed was Darwin with the importance of cross-fertilization that he closed his famous book on orchids, which marks the next great epoch in flower ecology, with the words, "Nature abhors perpetual self-fertilization." "The charm," says Mueller, "was now broken, and the value of Sprengel's work was at once recognized." "The merits of poor old Sprengel," says Darwin in his biography, "so long overlooked, are now fully recognized many years after his death."

In 1866, Darwin's *Origin of Species* and book on orchids was read by Hermann Mueller, a young teacher at Lippstadt, Germany, who thenceforth enthusiastically devoted the rest of his life to the study of the pollination of flowers. Many other investigators were also stimulated by these epoch-making books to study the charming problems of floral structure, as Delpino in Italy, Axel in Sweden, Hildebrand in Germany, Asa Gray in North America, and Fritz Mueller in South America. But they were all easily surpassed by Hermann Mueller, who is still regarded as the foremost of florocologists. In Thuringia and in the Alps he examined many hundreds of blossoms and observed the visits of insects by thousands. He was the first to collect and publish lists of flower-pollinators on an extensive scale, and the biology of flowers may thus be said in its broadest sense to have been established by him. Never since has this branch of botany been cultivated with equal success. His book, "The Fertilization of Flowers," ranks with the works of Sprengel and Darwin, and marks the third great epoch in the history of the ecology of flowers. It is illustrated by many excellent wood-cuts, the drawings for which were made by Mueller himself. It contains descriptions of the floral mechanisms of a great number of species of plants, with lists of

their insect visitors. It will give some idea of the immense amount of labor involved in its preparation to state that 5231 visits to flowers by 843 different kinds of flower-visiting insects are recorded.

Mueller had never forgotten his earlier delightful journeys among the Alps, nor its rich and brilliantly colored flora. For six summers he continued with great diligence to investigate its flowers, and the result was his second great work entitled "Alpenblumen," or the Flowers of the Alps. Here are enumerated 5711 visits by 841 species of anthophilous insects. It is impossible to read this account of the mysteries of the floral world in high altitudes without longing to visit the scene of his investigations. The short summers, the rapid (not to say impetuous) advance of vegetation, the simultaneous blooming of many species, the brilliant hues, the wealth of insects, and especially the great abundance of butterflies, against a background of snowy summits, form a most enticing picture. Mueller published a third book on flowers, besides many shorter papers.

To-day there are very few investigators engaged in studying the life histories of flowers. In North America they number less than half a dozen. Most observers are content to restrict their attention to the botanical side of the subject, and ignore the great company of pollinators. Even Charles Darwin and Anton Kerner, whose writings still remain an ever inspiring source of information, gave little heed to the ways of the insect guests. The reason for this is not far to seek. To collect and prepare lists of the visitors and to observe their behavior requires so enormous an amount of time, labor, and patience that the opportunity is possible to very few people. Suppose that a flower is in bloom for two weeks, then, on every calm bright day many hours must be devoted to this work, for the guests at the beginning of blooming-time may differ from those at its close. There follows the almost insuperable task, at least in America, of determining the names of the captured insects. With the exception of the butterflies we have no manuals of the different orders, and the literature is in a truly chaotic condition, many papers not being obtainable at any price. It is noteworthy that each of the three or four more prominent investigators of florocology in America has been compelled to work up the classification of the bees in his locality—a rather formidable undertaking in itself. So closely allied are the species and genera that no one can distinguish them without a special knowledge of the group, which in its relations to flowers exceeds all others in importance.

But the value of an acquaintance with the insect visitors can not be easily overestimated; for some species fly only in the spring, others only in the fall; some species visit only one kind of flower, others many kinds; some are most welcome guests, others are mere robbers. I should never have dreamed that the pretty nodding pink

blossoms of the twin-flower, with its sweet vanilla-like fragrance, are in our northern woodlands attractive to gnats alone. One afternoon a large bed of these delicate flowers was carefully observed, and eight visitors were collected. On examination they were found to belong to a single species of fly (*Empis rufescens*). Further observations show that in this locality this fly is probably the only guest. A burly bumblebee flew over the flowers without paying any attention to them.

Among aquatic plants living in freshwater rivers is the bladderwort (*Utricularia vulgaris*). The whole plant is submerged; but at blooming-time a flower-stalk is thrust out of the water, which produces deeply two-lipped bright-yellow flowers. I surely expected to find it a favorite of bees. But after repeated observations I have collected on the flowers in Maine only the long-tongued syrphid fly *Helophilus conostomus*. There is no way in which we can so easily learn the defects of flowers as to watch the behavior of insects upon them. No human eye can discover them so quickly. In a word, if we would fully understand the bright-hued floral edifices which so freely adorn the outdoor world we must study the *modus operandi* of their architects and builders.

Waldoboro, Me.

A FEW RANDOM NOTES ON THE WAY BEES "MAKE" HONEY.

BY ARTHUR C. MILLER.

[Most of us think we know all about honey production; and that is true if we consider the processes that take place from the hive to the consumer; but as yet no one has ever gone into details telling what takes place from the blossom to the comb, and for the very good reason that most of us would not take the time to see what is done, even if we knew where and how to look. With a specially constructed observatory hive by which the bees are compelled to build the edge of the comb up against the glass, it is possible to see what has hitherto been denied the ordinary observer. If we are not mistaken, Mr. Miller is the pioneer in the use of this kind of glass hive. In the following article he tells a story that is exceedingly interesting to the student of nature—a story that we believe will be verified by any one else who will take the time to watch the bees work when in the hives.—ED.]

The bee returning from the field with a load of nectar does several things which are quite contrary to the rules we have laid down for her. She does not rush for a cell to put it in; on the contrary, she spends a seemingly needless amount of time wandering about and inspecting cells. When at last one is found that seems satisfactory she enters it, feet up and back down. If the cell is empty she puts her mouth into the upper and rearmost angle, opens her mouth and mandibles, and at once a drop of nectar is seen to well up until it touches the cell. Slowly the head is turned from side to side, spreading the nectar against the corner of the cell. All the time the mandibles are kept in motion as if biting, though the tips do not meet. The outflowing nectar fills

the mouth, flows up over the upper lip (labrum), and fills the space between the mandibles. When the bee has emptied her sac she backs out of the cell, wipes off her face, antennæ, and tongue, stretches and plumes herself, and, likely as not, crawls into some cell or hangs in some quiet corner for a nap. Thus she may stay for a few minutes or for half a day. Busy little bee!

If the load is to be deposited in a cell already containing more or less honey the procedure is the same, except that mandibles and mouth parts are submerged in the honey in the cell. No matter how far the honey may lie out on the floor of the cell, the bee never gets her face in it, but tips her head out until it looks as if it would part from the thorax. In all the depositing of honey or nectar the tongue is never used, but is kept folded behind the head.

So far as it has been possible to determine, the nectar-laden bee never yields any of it to the other bees. This statement applies to times of plenty; for when the colony is on the verge of starvation the home bees do sometimes obtain food directly from the returning worker. If they do it at one time they may at another; but certainly such is not the common way when honey is being freely gathered.

At night the ripening process, which during the day receives little attention, becomes the work of a very large part of the bees. Over all vertical surfaces the bees spread in single layers, and each bee appears to have plenty of elbow room. Every honey-treating bee hangs vertically with head up. The mandibles are spread, the mouth opens, and a drop of nectar appears, increasing in size until it fills the mouth, flows up over the upper lip (labrum), and fills the space between the mandibles. Then what, for convenience, we will here call the lower jaw (labium) begins to move with a chewing-like motion, and this causes the exposed drop of honey to "pulsate." Slowly and steadily this is done, the bee sometimes continuing it with one drop for ten, twelve, or even more minutes; then there is a pause, the drop is swallowed, and the bee rests for a few seconds; then another drop appears, and the process is repeated. The volume of the exposed drop is somewhat less than the capacity of the honey-sac—estimated at a quarter to a third less.

Each individual bee continues her work until seemingly the nectar is so changed that it ceases to excite the nerves. When this stage is reached she generally deposits her load in a cell and goes to sleep, although sometimes she may take another sacful from some cell and resume her labors. Just what the age is of the bees doing this work has not yet been determined; but so many bees work at it that it seems as if bees of almost all ages take part.

When the bees have not room to store their loads after treating them they must needs keep them, and it is then that they secrete wax freely. The very process of "ripening" seems to cause the production of

much wax; but if the bees have to hold their loads the amount produced seems much greater. Perhaps it is not so much more as it seems.

That the ripening process is accompanied by wax production is easily proved by the following experiment: Feed a colony with thoroughly ripened honey diluted with about one-third its bulk of water. The bees will store and thicken this, but will not produce much wax—very little, in fact, unless they are getting some nectar at the same time. Feed another colony a syrup made of equal parts of granulated sugar and water, or, for more pronounced results, use more sugar. This colony will produce a lot of wax—so much, in fact, that if the experiment is continued for four or five days the new wax will be found stuck all over combs, frames, hive-sides, etc.

At the time the two colonies are being thus treated, two more should be allowed only what food they get from the fields, and these colonies used as "checks," i. e., colonies under normal conditions to compare the other two with.

The colony continues its ripening labors until about 11 P.M., sometimes a little later, occasionally as late as 1 A.M. The cause of the variation is unknown. All during this work the colony keeps up the deep hum, so well known and so welcome to bee-keepers. The cause of the humming is not determined. It does not seem as if the proportionately few bees fanning could cause it all.

An examination of the bees doing the ventilating is interesting, for the volume of air they drive from the entrance seems out of all proportion to the number of bees doing that work.

Most of such fanning is done at or near the entrance, and not by masses of bees all through the hive, as commonly supposed. There are occasions when fanning is done all through the hive, as when the heat is very great or when the hive is deluged with smoke; but these are not normal conditions.

The attention of students of the grand functions of the bees is called to the opportunity afforded for the secretions of the glands opening on the mandibles to mix with the nectar.

Providence, R. I.

[The statement has been repeatedly made that the ordinary bees on returning from the field, laden with nectar, do not deposit their loads directly in the cells, but pass them along to young bees in the hive, not old enough to go to the field; that these latter, in turn, deposit nectar in the cells, and then return to unload other worker bees that have come from the field.

Busy as a bee! It is popularly supposed that the bee works incessantly if we except the hanging-out in front on a very warm day when the entrance is contracted too much. This is a very interesting field for study and observation. If any of our readers have a story to tell different from that presented by Mr. Miller, we hope they will tell us what they have really seen.—Ed.]

Beginners' Questions.

In presenting this list of questions it should be understood that it is impossible, in many instances to do justice to the subjects in the short space here allowed, and for full particulars we refer the reader to our encyclopedia on bees—the A B C and X Y Z of Bee Culture—a book that is of inestimable value to the beginner and expert as well.

Q. Where can bees be kept?

A. There are few places in the country where one or more colonies of bees can not make honey. It is true that the natural surroundings may be unfavorable to the bees, but one who has had no experience is often astonished as to distance bees will go in search of nectar of the flowers. In almost every large city there are some bee-keepers who have bees right in the heart of the city, either in back lots or on the roof of buildings. Ordinarily, bees will go from one to three miles in search of nectar, but if there is none nearer they will go much further. There are cases on record of bees going seven miles from home.

Q. Do bees ever make trouble in a city?

A. It is very seldom that bees make trouble of any sort in a town or city, and if the bee-keeper is careful, there need be none at all. We advise placing the hives in the back yard as far away as possible from the general highway.

It is true that in some few cases city councils have attempted to pass ordinances declaring bees to be a nuisance; but no such ordinance is constitutional, as the supreme court of Missouri in what is known as the Arkadelphia case, has decided that bees are not a nuisance per se. A similar case was tried in Rochester with the result that a verdict was rendered in favor of the bees. Full particulars concerning these can be obtained by addressing General Manager N. E. France, of the National Bee-keepers' Association, Platteville, Wis.

Q. What must be planted for bees to work on?

A. Strange as it may seem, it usually does not pay to plant anything that is valuable only for the honey unless waste places such as roadsides or fence corners can be utilized that would be of no value in any other way. Very often the natural sources of nectar in a locality can be augmented by the sowing of sweet clover seed, and since this is becoming to be known as a valuable forage instead of a pest or weed, as it was formerly called, there is no question but that it pays to grow sweet clover for hay and thus secure some additional honey of fine quality, also. However, it must be remembered that each blossom yields only a small amount of nectar, hence there must be hundreds of acres of any such plant before any great difference will be noticed in the surplus honey produced, if there are very many bees in the locality. However, as stated first, almost every locality has enough natural sources of nectar to support one or more colonies without artificial pasturage.

Since alfalfa clover and alsike clover are being grown more and more even by the farmers of the East, there is every reason to suppose that there will be more honey produced from these sources in the future than ever before. Buckwheat is a good yielder and especially valuable for furnishing nectar in the late summer to keep up brood rearing.

Q. Do bees do well in a fruit country?

A. The fruit trees alone, unless there are acres and acres of them, do not usually furnish enough honey to be noticeable in the surplus supply secured, but of course there are many exceptions to this in localities where fruit is grown extensively. In this connection, however, it might be well to state that bees are a necessity in a fruit growing locality, for without their aid the blossoms do not set, that is the cross fertilization is not accomplished. It is true that the

wind and other insects distribute the pollen to a certain extent and thus fertilize the blossoms, but at the same time, if there are no bees at all a great many of the blossoms will not bear fruit. A simple experiment may be tried to prove this: Cover a branch of blossoms with coarse mosquito netting which will just prevent the bees from getting through, and it will be found that the blossoms on this branch will not bear fruit, even though the netting is removed as soon as the petals fall.

Q. Do bees work on ripe fruit and spoil it?

A. If the skin of the fruit has been punctured by some other insect or by the birds, it is true that the bees will work on the pulp and juice of the fruit thus exposed, but such fruit would be unfit for market anyway, hence the bees after all do no real harm. Bees by themselves can not possibly puncture the skin of fruit. Sound fruit, if kept carefully guarded from birds and other insects, will be untouched by the bees. This has been demonstrated over and over again.

Q. How many kinds of bees are there in a colony?

A. During the early part of the summer a normal colony consists of one queen, the only perfect female in the hive; several hundred drones (the male bees)—and any where from twenty to fifty thousand worker bees, which are undeveloped females. The queen is not the ruler of the hive as was formerly supposed, but is simply the mother; she lays the eggs. A good prolific queen in the height of the season will lay from two to four thousand eggs per day, or nearly twice her own weight, in twenty-four hours. Continual feeding by the worker bees enables her to do this. The drone is the male bee and he has no sting nor any suitable tongue with which to work; hence the drone does no work, not so much because he is lazy but because he has no tools to work with nor weapons with which to defend the hive. The workers are stunted females, and as their name indicates, they do all the field work such as bringing in pollen, nectar, building the comb and feeding the young.

Q. How many colonies can one man take care of?

A. This depends on the man and so this question can not be definitely answered any more than one could positively say how many acres of land one man could farm. However, one man with a little help in the busiest part of the season can usually care for as many as five hundred colonies if he is experienced. Colonies of bees in order to produce good results, must be properly taken care of. A hundred weak colonies not in good condition for producing honey by the time the main honey-flow opens, will not produce as much surplus as ten colonies that are very strong and in the very best condition at the time the main honey-flow begins.

Q. What profit can reasonably be expected?

A. As much as \$10.00 per colony has been secured where there are only a few colonies to the locality, but this is above the average. \$2.00 to \$3.00 a colony would be about the figure where there are a large number of colonies.

Q. How much increase can be expected in a year?

A. If natural swarming is allowed a fifty percent increase is perhaps an average. No colony should be allowed to swarm more than once, for the parent colony is too greatly re-

duced in strength if more than one normal swarm issues. Professional bee-keepers usually make their increase artificially, however, and it is not at all a difficult matter to double the number of colonies in a year. In fact, an expert, when all conditions are favorable, can increase a three-frame nucleus which is only about one-third the size of an ordinary colony into ten full size colonies by fall, but of course this is beyond the reach of the average amateur. The whole question of increase is fully explained in the A B C & X Y Z of Bee Culture.

Q. Will beating tin pans, ringing bells, etc., stop swarms?

A. No. Almost every swarm immediately after it issues will soon cluster anyway at some convenient point until the bees get their bearings. How the custom of beating tin pans, etc., started no one knows. If a swarm is inclined to make for the woods at once, the bees can be made to cluster very quickly if a good spray pump is at hand for a good drenching so wets their wings that they are forced to cluster until they can dry off.

Q. Is it possible to remove bees from hollow trees or the walls of a building?

A. Yes, this may be done without trouble but the easiest way is to cut down the tree or remove some of the siding of the building, as the case may be, but if this is impractical a device known as the bee-escape may be placed over the opening or entrance which will allow the bees to pass out but will prevent them from going back in again. If a hive containing comb is arranged close to the opening on the outside, all the bees may be secured in this way, or practically all of them except the queen and brood. A new queen will have to be on hand and introduced to the bees. Most of the modern books on bees describe the various processes of transferring bees from trees or buildings into hives, so that one who is desirous to start in this way need have no particular difficulty.

Q. What strain of bees is the best?

A. There are not as many different varieties of bees as of poultry, for instance, owing to the fact that since the mating of the queens and drones takes place in the air, the male parentage can not be controlled, hence if a number of different varieties of bees were kept in the same yard they would soon be hopelessly mixed up and a mongrel bee be the result. The Italian bees are preferred by the majority of bee-keepers in this country, although the Carniolan and Caucasian bees are beginning to be used somewhat where early brood rearing is desired.

Q. Can one who takes care of bees keep from being stung?

A. Yes, if necessary, one can so protect himself with a good veil, gloves, etc., that there is practically no danger of receiving a sting; but practical bee-keepers after they have been stung a very few times are not bothered very much in this way, for the stings lose their effect, that is the system becomes immune to the poison so that no swelling takes place.

Q. Is there any danger of bees stinging neighbors or their cattle?

A. There is some danger, but at the same time very little. Occasionally, sweaty cattle or horses if allowed to get in the direct line of flight of the bees, will irritate them so that they may be stung, but after all, such instances are not the usual thing. If proper precautions are taken, neighbors need not be annoyed in any way. If robbing is allowed bees are always more irritable.

Q. How may I know when bees are robbing?

A. When bees are working in the field there will be a quiet, contented hum that is very different from the excited high-key note that one hears when bees are robbing. At such times they are almost sure to be cross, and when it is allowed to continue they may

sting not only human beings but domestic animals. A careful examination of the apiary and surroundings may show that the bees are either robbing some hive or hives, or have got into the honey-house or kitchen, and are helping themselves to sweets. In the case of the building, the doors should be closed immediately. Toward night, they can be opened allowing the robbers to go back home. But doors should be kept carefully closed the next day and thereafter because the robbers will come back.

If the bees are robbing some colony or colonies there will be found more or less fighting at the entrances. Some bees will be stung to death; and after the colony is overpowered, robbers will rush in and out at a terrific rate. There will be a general uproar in the apiary; and if these conditions continue, other colonies that perhaps are not as strong as they should be, will be robbed and possibly overpowered. The remedy is, to carry the robbed colony or colonies down cellar immediately, where they should be kept two or three days. When set back on stand, the entrance should be contracted down to a space so that only one or two bees can pass at a time. For full particulars on this subject, see "Robbing," in the ABC & XYZ of Bee Culture.

Q. How can I distinguish the play-spell of bees from robbing?

A. On bright days, especially those days following inclement weather, after bees have been shut up for some time, one will often find an unusual commotion in front of some particular hive. Bees will be flying thickly before the entrance in such a way that a beginner might suppose it to be a case of robbing; but there will be no fighting, no bees struggling against each other, no dead bees, but, on the other hand, bees will be flying around aimlessly in front of the entrance, a few going in and some out. When there is robbing going on, there is a life-and-death struggle; and after the colony is overpowered the robbers will be rushing into and out of the hive at a furious pace. For further particulars, see answer to preceding question.

Q. What kind of hive is the best?

A. This question can not be answered definitely. Complicated patent hives are usually very little if any better than the cheap wooden boxes that they are sold at a high price to take the place of. The standard ten-frame hive is preferred by the majority of honey producers, but if comb honey is to be produced the upper part of the hive should be of a different style than if the bees are to run for extracted honey. Beginners in the North will succeed best with the ten-frame double-walled packed hive that is warm in winter and cool in summer.

Q. What are the different parts of a bee hive?

A. A regular beehive consists of a floor or bottom board; a brood chamber which contains the ten frames that surround the combs; the super that holds the square sections for the surplus honey, and the cover. The brood chamber is a plain box usually with notched or dovetailed corners to give added strength, and with the end of the box rabbeted at the top to hold the projections of the top bars of the frames that surround the combs. The bees are induced to build the combs in these frames by means of a sheet of what is known as comb foundations that is suspended in the middle of each frame, which acts as a pattern to enable the bees to build their combs straight. If this were not used they might build the comb crosswise of the frame or in bunches or in clusters, so that it would be impossible to separate one comb from another for purposes of inspection. The super or upper part of the hive gets its name from the fact that it holds the superabundance of honey. The modern bee-keeper does not rob his bees; that is, he does not take from them honey that they require for their own food, but simply removes the surplus of which there

is often ten times as much as they could possibly use themselves.

Q. How can I tell a queen cell from all the rest?

A. It is much larger than the rest of the cells and stands alone by itself. It somewhat resembles a long-pointed peanut, and it is built on the surface of the comb with the small end downward. Usually, queens cells are found on the lower part of the comb.

Sometimes old queen cells are left over from the year before and these should not be confused with fresh cells. The old ones do not have a finished look and are generally dark colored and very shallow, scarcely noticeable from the rest of the comb, except in size.

Q. What is the best way to introduce a valuable queen?

A. Select a couple of frames of hatching brood and place them in an upper story on top of a queenless colony with wire cloth between the two stories. After a number of young bees have hatched, release the queen among them. In about a week's time or after most of the bees have hatched, set the two frames of bees and queen down into the lower story and all will go well providing that any queen cells in the lower story are destroyed.

Usually there will be directions to go with these queens when sent out by mail. Of the cage plans for introducing, the push-in-comb-cage plan we consider the most reliable. For particulars regarding these, see "Queen-cages," on another page.

Q. What is pollen?

A. The ordinary diet of young bees is the food or pap made of a mixture of honey and pollen. Pollen is gathered from the flowers, and carried to the hive in large pellets packed on the bees' legs. Unless bees have sufficient pollen in the hives, brood-rearing can not be carried on, for pollen furnishes the nitrogenous element that is required.

Q. Some of the cells in my combs are half filled with a semi-hard, granular substance. What is it?

A. Bee-bread; that is, pollen packed hard in the cells for future use. Sometimes, this becomes old and stale so that the bees do not use it.

Q. What is propolis?

A. Propolis is a resinous red to brown substance that is sticky in warm weather, and brittle in cold weather. The bees use it for closing up gaps or openings, especially those openings that would let in cold air. They gather propolis from gums found on trees, and from buds. It has no commercial value.

Q. How can I remove propolis from my fingers?

A. A few drops of kerosene or gasoline will soften it so it can be easily removed by the use of soap.

Q. Do bees have diseases?

A. There are a few diseases of the adult bees such as dysentery, bee paralysis (not like paralysis of the human body); but the most serious diseases are those of the brood such as American or European foul brood. These, however, may be easily cured unless the bee-keeper is so negligent as to allow his whole yard to become diseased before he does anything about it. See A B C & X Y Z of Bee Culture.

Q. What causes the bees to carry their brood out of the entrances of the hives?

A. There may be several causes. First, the moth-miller, or moth-worms, rather, that have built their galleries through the sealed brood, destroying the young brood. These the bees will carry out and deposit in front of the entrance.

The most probable cause is chilled or overheated brood. Sometimes the combs, when handled by inexperienced bee-keepers, are ex-

posed for some little time to chilling winds. Such brood will die as the result of exposure, and will be carried out in front of the hive. Sometimes the entrances of the hives are too small in extremely warm weather. The bees are unable to ventilate properly, and the hives become overheated, thus killing the brood. The result is, it is carried out and left in front of the entrance. The third cause is poison gathered from fruit-trees by bees during spraying time. The brood dies, and is carried out as before.

Q. I have noticed a fine powdery substance on the bottom board. Does this indicate that something is wrong?

A. No, this is merely bits of cappings gnawed off by the bees or bits of comb, wax, or propolis. There is no occasion for alarm when this is found.

Q. What is the best way to get rid of moths?

A. Do not listen to any one who wants to sell you a patent moth trap or moth-proof hive. Strong colonies of vigorous Italian bees protect themselves against moths and moth larvæ, so that this trouble is practically unheard of in an Italian yard. Of course, if colonies are allowed to get weak and to degenerate moths may affect an entrance and make trouble, but not otherwise.

Q. What is a bee smoker?

A. A device for blowing smoke on the bees—not to stupefy them but to cause them to fill up with honey so that they are better natured and thus more easily handled.

Q. What is the best fuel for smokers?

A. Unquestionably greasy waste is best, such as can be obtained at any ordinary machine-shop, for the asking. Rotten wood, planer shavings, old rags, etc., do very well.

Q. What is the difference between "comb" and "extracted" honey?

A. Comb honey is produced by the bees in small, square boxes and sold in this way just as the bees left it. The extracted honey is the liquid honey thrown out of large combs filled by the bees, in a centrifugal honey extractor which works somewhat on the principle of a cream separator. That is, the liquid honey is thrown out of the cells leaving the comb as good as ever and it is put back in the hives and filled again by the bees. For this reason the extracted honey is cheaper as the bees do not need to build new comb each time.

Q. Which is the more profitable to produce, comb or extracted honey?

A. This depends largely upon circumstances. One who has but a few colonies had better produce comb honey, for the equipment required for extracted honey production is quite expensive and the outfit would usually not be warranted for a very few colonies. Professional bee-keepers, the majority of them at least, produce extracted honey largely. Nearly twice as much of the latter can be produced as of comb honey, but at the same time it brings only about half as much in the market as comb honey.

Q. Can comb honey be manufactured by machinery so as not to be told from genuine?

A. No, this is impossible. Comb honey has never been made by machinery and never will be, in spite of many newspaper statements and magazine articles to the contrary. The A. I. ROOT COMPANY, in order to show clearly that there is no such thing as manufactured comb honey, has, for nearly thirty years had a standing offer of \$1,000.00 for a single section of comb honey made by machinery that so nearly resembled the natural product as to deceive the average person. The fact that no one has ever been able to claim this money, shows conclusively that there is no such article on the market. There are plenty of reasons why such a feat would be impossible, but lack of space forbids the mention of them here. See A B C & X Y Z of Bee Culture.

Q. When extracted honey granulates is that an indication that it was adulterated with sugar?

A. No, for almost every kind of pure honey will granulate or crystallize in time. Some kinds of honey produced in the South will crystallize in only two or three days' time, but usually from two to six months is required. The honey may be returned to the liquid state by heating it gently in hot water. For the very best results the water surrounding the dish of honey should be no hotter than 140 degrees. A temperature much higher than this will give the honey a burnt flavor.

Q. I have some combs that contain granulated honey that I cannot extract. What shall I do with them?

A. Soak them in warm water and place in a super above a strong colony. The bees will usually clean out the cells although the combs may have to be wet two or three times before the work is finished.

Q. What is the reason my bees will not go into the supers and store honey?

A. Several causes might be assigned. First, no honey coming in, or at most a very light honey-flow; second, a colony too weak. There must be a large force of bees to store enough honey to fill the brood-nest to keep up brood-rearing, and yet leave a surplus to be stored in the sections or extracting-combs above. Third, sometimes a strong colony in a good honey-flow will not enter the super. In that case, if other bees are storing, an examination of the brood-nest may show that the brood-frames in the colony that sulks are "honey-bound" — that is, honey has been stored in brood frames until the queen has been compelled to stop laying. To remedy this, uncap all the combs and put on some sections from some other colony, which the bees have already partly drawn out and filled. This will usually have the desired effect.

Q. How can finished honey be removed from the hive?

A. The old way was to set the hive over a hole in the ground in which there was some burning sulphur, and after the bees were all killed to take the honey out with a spade. The modern bee-keeper as mentioned above, does not remove the honey the bees need but simply takes the surplus. A board containing what is called a bee escape, is placed between the super and brood chamber and the bees go down through into the lower part where the brood is and cannot get up again. In a few hours they are all out of the super and the surplus honey can then be removed without the knowledge of the bees. There is then no uproar, no stings, no confusion and no trouble of any kind.

Q. What is done with bees during winter?

A. If the colonies are not already in double walled hives the space between being filled with shavings or leaves, a winter case may be put over the regular hive and packing material put in after which a water proof cover is put over the whole thing; or the colonies may be wintered in a cellar which is kept reasonably dark and even in temperature. Except in the northern part of the northern states, however, it is usually safer to winter on the summer stands in double-walled hives or other hives especially packed for the cold weather. For further particulars, see A B C & X Y Z of Bee Culture.

Q. What is a winter nest?

A. It is a space of empty cells in the central combs three or four inches below the top bars. Bees if left to themselves will form this clustering space in the empty cells so that they can get closer together for warmth. If this winter nest is disturbed in the rearrangement of combs, it must be put back.

Q. How do we determine when a colony is strong enough to go through the winter?

A. The answer to this question depends on

the latitude or climate, the kind of hive and whether the bees are to be wintered outdoors. In a warm climate fewer bees will be required than in a cold, but more stores will be needed. In a cold climate for outdoor wintering we figure on not less than 7 frames covered with bees. For cellar wintering 4 or 5 frames will answer but more will be better. In the extreme south two or three frames of bees may be enough providing pollen and honey can be gathered in late winter. In all cases, it is better to have a hive full of bees; but in that case there should be 5 or 6 frames of stores or the equivalent in 8 or 10 frames.

Q. How can I stimulate brood rearing in the fall when queens ordinarily stop laying?

A. Queens two or three months old will lay when queens one or two years old will not. We usually advise having young queens in the fall, not only because they stand the winter better, but because they supply the hives with a force of young bees, so necessary for successful wintering. But old queens can be made to lay to some extent by feeding outdoors a sweetened water consisting of 15 parts of water to one of granulated sugar. This mixture should be thoroughly stirred, and then put into Simplicity or Alexander feeders, about fifty yards from apiary. The feeders will need to be filled two or three times a day, depending on the number of bees in the yard; but do not give them more than they can take up in a day, for in warm weather it will sour.

Q. What is the best way to unite bees in the fall?

A. If there are two colonies neither of which have strength enough to go into winter quarters, the weaker should be united with the stronger. Ordinarily, the old bees of the moved colony will go back to the old stand. To provide against this, proceed as follows: In the cool of the morning, or better, the last thing at night, smoke the bees thoroughly that are to be removed. Pound on the hive considerably, so that they will be demoralized. Carry the hive and set it down beside the other and shake the moved bees in front of the entrance of the other hive. If they are pure Italians, no smoke will be required. If they are dark hybrids or blacks, it may be necessary to examine the bees in fifteen or twenty minutes to see if they are fighting. In this case, smoke the hive thoroughly and shut it up. After they are nicely united rearrange the combs to form a winter nest.

Q. In uniting, what should be done with the queen?

A. Where there is no choice especially if neither queen is valuable, the two lots of bees can be united, and, as a rule, one of the queens will be left and the other destroyed. But where there is a choice, which is usually the case, the better one should be caged and introduced, and the other destroyed or put into some other colony.

Q. What is meant by balling a queen?

A. When bees are hostile toward a queen, they will cluster about her very thickly, sometimes forming a ball of bees anywhere from one to three inches in diameter. Every bee in the ball seems to be struggling to get at her to sting her. Unless she is released she will either be smothered to death or stung. To release her, use plenty of smoke, blowing it on the ball, until the mad bees disperse and then pick her up and cage her. Another way is to dip the ball in a pail of water, when the bees will immediately float away from her.

Q. If colonies die through the winter may new swarms the next season be put in the same hives?

A. If the bees did not die because of the result of disease, but simply starved or chilled, there is no harm in putting new swarms in these same hives. By careful attention, however, the winter loss may be reduced to a very small percent.

Our Homes

A. I. ROOT.

I was a stranger, and ye took me not in.—MATT. 25: 43.

Be not forgetful to entertain strangers, for thereby some have entertained angels unawares.—HEB. 13: 2.

And if ye salute your brethren only, what do ye more than others? Do not even the publicans so? —MATT. 5: 47.

Come, ye blessed of my Father, inherit the kingdom prepared for you from the foundation of the world; for I was an hungered, and ye gave me meat: I was thirsty, and ye gave me drink; I was a stranger, and ye took me in.—MATT. 25: 42, 43.

Mrs. Root has quite a fondness for reading *old* books—those, for instance, that she and I read together when we were first married, and she persists in reading them again, even when I tell her there are new books just as good, or even better; and therefore when we started on our two-days' trip to our Florida home she laid out to read on the way an old book entitled "Knight of the Nineteenth Century," by E. P. Roe, as she has always had an especial fondness for all of Roe's books. Well, one day when I began to get a little tired of looking at the landscape I happened to glance at the open book I had read perhaps 50 years ago. At that date I was not a professing Christian; and although I found the book entertaining I fear I did not get hold at all of the great point the author had in view when he tried to show forth what is *real* Christianity, or, if you choose, what the real Christlike spirit *means*. The leading character is a young man who, through faulty bringing up, "went to the bad." He tried to turn over a new leaf and atone for his errors, but everybody seemed to make sport of his efforts to retrieve, and he became discouraged and went down again, lower and lower, until even his own mother lost faith in him; and when he was truly converted, *she* seemed to be more skeptical than any one else. When he tried to follow the teachings of his Savior, his rebuffs and discouragements from a cold and unfeeling outside world were almost unbelievable, did we not all see this same thing still going on almost everywhere. I was particularly impressed with his reception at one of the fashionable churches, where a kind friend had induced him to attend. I shall have to confess I have for some time been feeling troubled about the final outcome of so much money and *fashion* that is becoming so great a part of our town and city churches. In my previous Home paper I mentioned a pastor so eloquent and gifted that he was offered and accepted a much larger salary, while he was at the same time *guilty of murder*. What shall become of us if we continue to permit "grafters" and hypocrites to get in among the clergy?

After finishing the book, I told Mrs. Root I wished every member of GLEANINGS could read this old book, by one of God's faithful and devoted servants (she got it by mail of Sears, Roebuck & Co., for 33 cts.). Well, while having this whole matter in mind

you can imagine with what interest I read the following letter:

Mr. A. I. Root:—I have just this hour received your journal; and since your department, Mr. Root, is the very first and often the only thing I am reading in GLEANINGS I notice the letter that Mr. Klabuhn, of Conneaut, O., has written you, and your reply to it. (See page 707, Nov. 15.) I am a German myself, and this is only the sixth year I have been in this country. In other words, I am another "stranger" to you Americans.

Now, before I proceed any further let me thank you for the generous spirit with which you answer my landsman's letter. I pay you my highest respect for your nobility of mind, since Mr. Klabuhn must inevitably, although without intention, have slightly offended you. The reason for Mr. Klabuhn's opinion is, no doubt, his experience.

I simply love to read all your talks; but I must confess that I have never been to church in this country—not because I don't believe in God and his church, but simply because I have not yet found a human being here in America who would practice a true neighborly or Christian spirit. All with whom I come in contact have shown me, beyond the shadow of a doubt, that they can spare me some of their time only if there is some *advantage* in it for them—even ministers, every one of the few with whom I come in touch.

When I landed, six years ago, I could not speak English, and I began right away to study the language. After a while I became a member of the Y. M. C. A. of Providence, R. I. There I was, sitting all alone, and none of your young men of that organization spoke a social word to me, and my heart was yearning for social intercourse. Mind, Mr. Root, they did not yet know my way of thinking. They simply left me alone, and literally discouraged me from getting acquainted with them. I think they felt too important to associate with a foreigner.

A little later, again, I went to Boston to find work in that city; and there, being a member, I frequented the Boston Y. M. C. A.'s reading and other rooms, and there I met with the same fate. Only one lady clerk and one gentleman clerk of that institution proved an exception, inasmuch as they were really friendly to me, and gave me information quite cheerfully. You know both the lady and the gentleman were studying German, and tried to get me talking German with them, which I, by the way, was glad to do.

The Boston Y. M. C. A. maintains a house orchestra which practices on certain evenings, and plays Sunday afternoons for about an hour for the benefit of the other members. Now, since I am a violin player I offered to join this orchestra. Well, of course they let me play with them; but do you think, Mr. Root, they would let me get acquainted with them in a personal way? Not much! I felt exactly as if I were coming, playing, and going without being noticed at all. And they were, all of them, highly respectable members of that excellent organization. How I felt, you may or may not imagine. But all those and other experiences shattered my confidence in humanity and my belief in the sincerity of the men who pretend to be Christians. I do not wish to flatter you, Mr. Root; but I think you are one of the very few exceptions which do exist, because your work proves it to some extent. I firmly believe in our Lord, but I do not visit the church, and I often feel that I am wrong in not going to church.

Now, I wrote you all of this to show how one may be educated up to the point where Mr. Klabuhn seems to be. He says in his letter, "I am an *old* German." Now I am a *young* man—31 years of age; let me live another 20 years, and if, during that time, I meet with the same conduct of men, I shall, perhaps, suffer morally for it. Or will those suffer who made the misanthropist of me?

As it is, I am still wavering, and can not for the life of me decide regarding this vital question—I, e., whether I should visit the church and pretend to believe that my fellow-men are Christians, when, right down in my heart, I *know* they are *not*.

Plymouth, Mass., Nov. 22. BERNHARD KUNZ.

Dear friends, *you* especially who love the

Lord Jesus Christ, I hope you will read the above plaintive letter again and again, and then I hope you will go out "into the by-ways and hedges" and see if there are not some near you that you have overlooked, as our good friend describes. You who belong to the Y. M. C. A., look around and see if these things are true in *your* locality. Remember who it was that said, "Inasmuch as ye have done it unto the least of one of these my brethren, ye have done it unto me."

Now I want to suggest gently to our good brother who writes the letter that possibly there is at least just a little tendency to uncharitableness on his part. Are you not, my good friend, a little too modest and oversensitive? Are you sure you are doing your part? and is it not possible you are a trifle hard to get acquainted with? I want to quote right here something from the *Sunday School Times* that has done me a lot of good:

THE DEFEAT OF INJUSTICE.

No one can ever afford to think about any injustice he receives. It is disaster and destruction to do so. It is like deliberately lifting a glass of poison to our lips and swallowing it. Injustice inflicted upon us never harms us until we dwell on it. While we ignore it, and do right, it is powerless against us. When we begin to turn it over in our mind, it starts its murderous work upon us. It soon exaggerates itself, blinds us, rankles, inflames, embitters. It breeds self-pity, which quickly reduces us to a condition of worse than helpless uselessness. Jesus paid no attention to the awful injustices of his lot. We can not afford to do other than he did, with our lesser injustices. If love is our master-passion, thinking no evil and bearing all things, we shall live emancipated from the misery of dressing our own wounds. Such wounds heal quickly when we are lovingly busied with the needs of others.

The above sounds a little extreme, I admit; but I am sure it is God's message, nevertheless. In troubles of this kind we need to exhort strongly the parties on *both* sides to wake up and be ready to go a little more than half way. The editorial above* does not very clearly define the difference between personal wrong and a wrong against community; but the distinction is implied. I know what it is to dwell on some indignity or abuse until I am kept awake nights; and I know it is true that, if dwelt on, such things grow and enlarge, and finally spoil one's peace of mind. My father for several years was unhappy because a line fence encroached on his land. The surveyors told him the fence *was* over on his territory without question, but advised, as it had been there so many years, to let it rest to save quarrels and possibly a lawsuit with a neighbor; but because the surveyor who gave this advice belonged to our church, father had his own name taken from the church-roll, and could talk about and think about nothing else. Mother and the older children, the pastor of the church, and the deacons pleaded with him; but he persisted, and quoted, "right is right, and wrongs no

man," until one Sunday I persuaded him to go with me to a mission Sunday-school I was conducting in one of the worst points in our neighborhood. A lot of nicely dressed little girls and boys recited texts from the platform, and the zeal and enthusiasm of the whole school were truly inspiring. On the way home I asked him if such a work was not far more important than the value of a little strip of land of less than an acre. He assented, and gave me his promise to drop for ever the line-fence quarrel, and kept his word, went back to his church, and died at peace with God and with all his fellow-men.

HOW TO SUCCEED IN JOURNALISM, ETC.

I wonder how many of the editors of the fifty or sixty poultry-journals that come to our office by way of exchange read *my* writings. Well, I hope they will read *this*, even if they do not read what I say about poultry. While there are many good things to be said about the poultry-journals, there is one great and grievous fault with most of them, and a matter that can be easily remedied. It wants a little push and gumption, getting up early in the morning, or something of that sort. It is this: These journals are allowed to go out to the reading public without being inspected and corrected. I refer particularly to the typography. For instance, the printer or compositor will pull out a line to make some needed change, and then he puts it back without getting it in the proper place. Sometimes it will be at the bottom of the column, and sometimes it will not be found anywhere. He evidently forgot to put it back. The result is that the reader, when deeply interested in some article, finds a line gone so as to make the whole thing nonsense. I often spend a good deal of time in going down the column to find the missing line somewhere, where it makes another jumble. Now, this is a stupid trick of the one who puts the lines into page form to be sure; but he is not *altogether* to blame. Every journal or periodical of any kind that hopes to succeed should have somebody who is conversant with the subject-matter to read over carefully every bit of matter before it goes to press. This person or expert, which he ought to be, should be trained to note every letter upside down, bad punctuation, bad spelling, or any thing of that sort, so that, when the periodical meets the eye of the one who pays his money for it, it will be clean, and clear up to date. Our high-priced periodicals of wide circulation have two or more proof-readers in order to be sure that no blunders are allowed to pass.

Now, some of you may think this is a small matter; but that is another "typographical error." Leaving out a line as I have mentioned, bad spelling, and bad punctuation, stamp a periodical at once as second-class or not strictly reliable; and if the matter is not mended the journal soon fails for lack of patronage. When GLEANINGS was first started, nearly forty years

* Have we any other periodical whose editorials occupy such a high moral stand as the *Sunday School Times*? And is not the above sentiment characteristic of this same clean home Christian sheet?

ago, I realized the importance of this very thing; and under no circumstances was a single number allowed to go to press before I myself had carefully scanned every page and every line. I sat up nights and got up early in the morning; and when I was obliged to leave home, proofs were mailed me, and a boy often rushed over to the cars just as I was getting on, to give me a proof-sheet which I corrected on the train and mailed back. The reason why GLEANINGS was a success from the very start, and kept increasing and spreading every year for almost forty years, is just because we have taken such scrupulous pains to have it clean, correct, and reliable; and I am glad to add that perhaps no other one has stood by me and helped me in this work as has my good friend W. P. Root, who is now taking down these words stenographically. He has been my right-hand man in this effort to have our journal fully up to the standard of our first-class magazines for over thirty years. Just a few days ago I laughingly told some of our friends in the printing-office that I had for the first time in my life found our old friend at fault in spelling; but a more careful investigation showed that he was not entirely at fault after all, as the mistake was in the choice of a wrong word.

And now I wish to say again to the editors of the poultry-journals, this one thing I have been talking about may turn the scale between success and failure. If you expect your respective journals to win a place among the journals of our land you must have them clean and readable. I know it takes good, earnest, faithful work, early and late; but that is the price of success, and the only price.

By the way, with the present enthusiasm for poultry a new poultry-journal starts about every month,* but I am sorry to add that a poultry-journal dies about that often. So far as I know, there is not a single poultry-journal published at the present time in the whole State of Florida, with all its possibilities. One was started a few years ago, but it failed, principally, I think, for the very reason I have mentioned.

I am pleased to add, in closing, that our foreign journals are beautiful specimens of accurate and fine mechanical work; in fact, it is rather proverbial that the English, especially, never permit any thing to go out to the reading world unless it is first-class in regard to typography; and they really have some reason for calling us, as they often do, "a lot of shiftless Yankees."

CHUFAS, SOY BEANS, DANDELIONS, PARCELS POST, ETC.

Mr. Root:—I have read what you say on pages 608, 609, on soy beans and chufas for chickens, etc. I have never succeeded in getting my White Wyandottes to eat either soy beans or chufas, and

*Perhaps you will excuse me for saying right here, that during the past forty years a dozen or twenty bee-journals have been started; but sooner or later most of them have gone under, principally because of their carelessness along the line I have mentioned.

have offered them on a few occasions. I have had chufas dug up and lying on the grass two or three weeks, with alternate rain and sunshine, where the chickens could help themselves (sixty, old and young), and have not missed one nut.

You quote an advertisement of soy-bean meal, and seem to infer that it is merely soy beans ground up. I believe this meal is a by-product from the soy-bean oil-mills of China or Manchuria, just as our linseed meal is of our linseed-oil mills. This meal is imported very largely in Europe for feeding stock, as our linseed meal is.

You say chufas, like other nuts, are rich in protein and carbo-hydrates. You should have said, rich in protein and fat. Chestnuts are, I believe, the only nut rich in carbo-hydrates, while nearly all are rich in protein and fat—especially the latter.

I notice you are getting out a booklet on buckwheat. I should like to suggest that you get some one well informed on the subject to write on the use of buckwheat for green-manuring, killing persistent weeds, and as a nurse crop for sowing alfalfa, crimson, and other clovers. I have seen it advised very strongly for the latter purpose—in the *Rural New-Yorker*, I believe. Summer is deemed by many the best time to sow alfalfa, red and alsike clover, and crimson clover can be sown only then.

I note in *Ohio Bulletin No. 207* that cotton-seed meal is rated on the favorable side as stock feed; and in my reading I notice a flour is being made from cotton-seed for bread-making. We have need of just such a product for mixing with our one-sided acid-producing white flour to make healthful bread.

Another thought on buckwheat. May it not be sown early, allowed to blossom for the bees to gather the honey, then turned under, and another crop of buckwheat sown for grain, honey, and as nurse crop for clovers? Too much can hardly be known by bee-keepers about buckwheat and clovers.

Would it not be feasible to sow buckwheat in the buckwheat belt, sowing alsike at the same time, then let the bees gather the buckwheat nectar, you harvest the buckwheat, then let the bees gather the alsike nectar the following June, cut a crop of hay, possibly a crop of seed, then repeat the process, getting two crops each year, and two gatherings of nectar, while enriching the land with nitrogen at the same time? I believe it can be done, and bee-keepers are the ones to do it. Buckwheat is quite profitable where conditions are favorable, and alsike for seed is very much so.

As stated above, I have about sixty White Wyandottes, and can not notice that a piece is missing from a single leaf of the dandelions growing all around my grounds. Possibly the reason is that my chickens have full liberty, and thus may obtain what they like better—insects, grass, etc. They do eat great quantities of grass, I know, as I see them doing so, much of the time; and a hawk killed one and tore open its crop, which seemed to be stuffed with grass solely. Is it not likely that your Leghorns found what suited them? I am very fond of dandelion greens, and consider them healthful.

I note you advise cooking ground wheat thoroughly before eating. I believe this to be an error. It is apt to encourage too rapid eating, and cooking seems to necessitate the use of sugar to some extent, and this, I feel certain, is wrong. Our nutrition scientists have found that the average American dietary is about 17 per cent protein, 25 per cent fat, and 58 per cent carbo-hydrates—more protein for growing children and those at hard labor, and less for the aged and inactive. By looking at a table in my letter published on p. 396, 1910, you will see that wheat has protein, 11.1 per cent; fat, 1.7 per cent; carbo., 75.5. Granulated sugar is 100 per cent carbo-hydrates. Thus wheat is 30 per cent above a balanced ration in carbo-hydrates, and every grain of sugar makes it more so, while it has only about one-tenth the fat it should have. Therefore butter or cream, not sugar, is the proper thing to add to help balance it. Nuts, cheese, or other foods rich in fat or protein, should go with wheat; sugar, never. Rolled oats are much better balanced, but need fat to balance. Americans consume an average of about \$5.00 worth of sugar per capita per year, and great quantities of molasses and syrup in addition. If this were reduced to one dollar, and the remainder expended for milk or butter or cheese, or even for honey, we should be infinitely better off.

I note what you say about parcels post. Too much can not be said for this great boon to our producers and consumers. The middlemen are the

only ones that would be hurt. The Postoffice Department is run as a political machine, to give fat offices to henchmen at immense expense. About ten million dollars could be saved annually by abolishing the salaried postmasters, leaving the assistants to do the work as they now do. This would also greatly benefit the people by removing and quieting the many disturbing, offensively partisan politicians. I know a postmaster who has a business of his own where he may be found six or eight hours a day. He drops in at the postoffice two or three times a day, usually, and spends the rest of his waking hours at the club. About the hardest work he does at the postoffice is drawing his salary of \$200 a month. It costs me 16 cents to send a pound of laundry to the agent at the postoffice nearest my own, two miles away. A 300-lb. man with a 150-lb. trunk and a 50-lb. suit-case may go on the same train for 5 cents. Is that good business management? I can send the pound package to New Zealand, 10,000 miles, for 12 cents. Yet the government forbids the railroads charging more for a short haul than for a long one. The *Farm Journal*, published in Philadelphia, price the paper just double for delivery in Philadelphia that they price it for delivery in San Francisco, Alaska, or Mexico. Is that business? A law of the United States forbids any one carrying letters or packages (mailable) between postoffices; yet the express companies are allowed to carry nearly all daily papers, and millions of other packages under four pounds, greatly injuring the government. If a common citizen attempts to use a postage-stamp a second time it may cost him a heavy fine and imprisonment; but the express companies may defraud the government out of millions of dollars with impunity.

If you have not seen the document on parcels post by Hon. David J. Lewis, Cumberland, Md., you should ask him for a copy and read it. His is the best solution of the parcels-post question, I believe. He proposes to buy the express companies for some forty millions of dollars and run them at cost to the people. He shows that the express companies have contracts with the railroads to carry expressage at about $\frac{3}{4}$ cent a pound, while mail costs the government over 4 cents. Most of the parcel-post advocates talk 8 cents a pound, which is prohibitive, and of no value to producers or consumers of one pound in a thousand. Personally I would not be in favor of paying the express companies for their charters or contracts, deeming them thieves, robbers, and law-breakers; and thieves have no right to stolen property. But it would take years of litigation to oust them, and it would be cheaper for the people to buy them out and get the benefits of low rates of transportation. By all means write for a copy of Mr. Lewis' document and read it, and then tell your readers to do likewise. It is an eye-opener by a man who has studied the question thoroughly, and written ably on it. The document is free, Mr. Lewis being a Congressman.

A READER.

My good friend, there are two reasons why your chickens decline soy beans, chufas, and dandelions. First, they are not *hungry* for green food, like the flock belonging to my daughter. Second, they have not been *educated* to eat these things. This whole matter comes right along with the statement from so many that cattle and horses will not eat sweet clover. They have not become acquainted with sweet clover. Domestic animals, like human beings, become accustomed to a certain diet, and very often think they can not live on any thing else. Changing the food of a lot of chickens to something they are not used to will often stop their laying. This has often been commented on. I feel sure you can teach your chickens to eat chufas, soy beans, and dandelions. Down in Florida, where green stuff is often scarce, the poultry seem to eat every thing green greedily. As an illustration, it is of no use to try to grow potatoes if the chickens can get at them. They will eat

off the tops and then scratch out the tubers and eat them. A hen with chickens is especially expert at that kind of work.

The book we sell on green manuring mentions particularly plowing buckwheat under, two crops, one right after the other. Crimson clover and alsike both do splendidly when sown with buckwheat in July or August.

Parcels post is coming; and if our great nation of people keep urging, it will come all the sooner.

I agree with you in regard to the excessive use of sugar. My health is very much improved since I have given up sugar for so long a time that I have almost lost my appetite for it. Sugar on fruit or any fruit sauce spoils it for my use. Very likely you are right about using uncooked wheat. That is Terry's great forte, as you may recall.

ABSCONDING SWARMS, AND SOMETHING ELSE.

The following is from our good friend Calvin S. Hunter, of Seven Mile, O., the man I visited, and which visit I reported on these pages—the man whose hobby has been, during a good long life, *more* corn and *better* corn. He is also something of a poet as well as a most earnest Christian, as you will gather from the little poem at the end of his letter.

Mr. Root:—I am sure you will be glad to hear how the four swarms of bees that came to me last season in five days are coming on. They were surely welcome, for we are very fond of bees, and had none. We think that the "streak of luck" was to include five swarms in five days. But one was lured into the hollow of a great maple near by. They have done remarkably well, so that no neighbor who needed honey has been disappointed, and our bee inspector says they are the nicest black bees he ever saw. I have hopes that my luck has not entirely changed; for, although I have tried to prevent swarming, yet late in May, this year, one of the swarms showed signs, and so I got a hive ready; but before I got away, here came a swarm rolling like a balloon down the lane from the west gate, and it just covered the lid of the hive I was fixing, so I feared the queen was outside; but it was all right.

I send you some of my verses, entitled—

THAT NEW LIFE.

We are nearing that home where our loved ones must sleep.

And the friends are so weighted with sorrow;
But though hearts are bowed down like the willows
that weep,

Yet we know we shall meet them to-morrow.

Refrain.

For they'll watch and they'll wait at that beautiful gate;

They will cherish fond memories ever;
Tho' life's sun disappears in the mists of the years.
Yet that new life, it fades not—no, never.

Oh! we're fast passing through this dark valley of tears;

Each kind friend that we lose gives us warning
That it may be to-day, and can be but few years
Ere we all greet that heavenly morning.

Then we'll keep a brave heart while forgetting our fears.

Tho' earth's ties ruthless Time may soon sever;
For life's sun it sinks fast when 'tis weighted with years.

But that new sun will shine on for ever.

NO. 2

Editorial

THE Ohio State Bee-keepers' Convention will be held in Springfield, Feb. 21. Further announcements later.

MR. GEORGE S. DEMUTH, now of Washington, D. C., in the Bureau of Entomology, calls our attention to the fact that the picture on the outside cover page of our Christmas issue was taken in the apiary of Mr. S. D. House, at Camillus, N. Y.

BULLETIN No. 75, entitled "Miscellaneous Papers on Apiculture," has just been issued by the Bureau of Entomology, Washington, D. C. It probably can be obtained by any bee-keeper by applying to the Bureau of Entomology or to the Superintendent of Documents. This bulletin comprises "The Production and Care of Extracted Honey," by Dr. E. F. Phillips; "Methods of Honey-testing for Bee-keepers," by C. A. Browne; "Wax-moths and American Foul Brood," by E. F. Phillips; "Bee-diseases in Massachusetts," by Burton N. Gates; "The Relation of the Etiology (Cause) of Bee-diseases to the Treatment," by G. F. White; "A Brief Survey of Hawaiian Bee-keeping," by E. F. Phillips; "The Status of Apiculture in the United States," by E. F. Phillips; "Bee-keeping in Massachusetts," by Burton N. Gates. It contains 125 pages the size of this. While these papers have been published heretofore, the various editions have been exhausted, and this bulletin is a compilation of them all.

A SEVERE COLD SPELL.

THE fore part of winter was mild all over the United States; but during the fore part of January the weather turned severely cold in most of the Northern States, with a driving wind. Even in semi-tropical California, the temperature has gone down to freezing and below; and there has been a desperate fight on the part of some of the orange-growers to protect their groves. This they have been doing by building fires among the trees, thus generating a large amount of smoke. The same thing has been done in Florida. At this writing, Jan. 11, there is no letup in the severe cold in any portion of the United States. It has not and probably will not continue long enough to do any

great damage to the bees. The clovers will not be injured, because there has been a heavy fall of snow over most of the North. Lots of snow is always favorable to clover.

THE CIRCULATION OF GLEANINGS BOOMING THESE DAYS.

GLEANINGS has been late for a couple of issues back; and for this issue, perhaps, we shall have to beg the indulgence of our readers till we can catch up in our printing department. We have just purchased a new printing-press, which, together with the two big machines* already in, ought to enable us to catch up very soon. We have recently installed a new linotype, or type-setting machine, and all together the printing-house of GLEANINGS is "as busy as a bee," even if it is in the dead of winter and the bees are all asleep.

New subscriptions and the renewal of old ones have been coming in with a big rush. Considering the poorness of the past season, and the bitterly cold weather we are now having, we are truly thankful for the generous support of our friends.

WINTERING BEES IN CLAMPS.

In certain parts of the northern States the custom of burying hives of bees in the ground during the cold weather is very prevalent; but lest the uninitiated should get the idea from our picture on the cover of this issue that this plan solves the wintering problem universally, it may be well here to mention some of the restrictions which, while they have been given before, can nevertheless bear repeating.

The soil as shown at the left, in the picture, is sandy. This is a vital requirement; for in a clay soil the combs in the hives would "sweat" and become moldy, and the bees would dwindle away rapidly because of the impure air, there being no chance for escape of moisture nor for the influx of fresh air, as the clay is not porous.

Even with a sandy soil, if the winters are open with considerable warm weather when

* All of them are four-roller book-presses, and two of them have automatic Dexter feeders. In fact, we have one of the best-equipped printing-shops in the United States.

bees may fly, we question very seriously the advisability of wintering in clamps or trenches. Under such conditions the double-walled hive is the best solution of the problem; for the results secured are so uniformly satisfactory when other conditions are favorable that no better plan is needed.

This picture on the cover is another one made from one of Mr. Hutchinson's old negatives. Our older readers will recognize it as having been used before; but we considered it good enough to use again.

BEST PRICES JUST BEFORE CHRISTMAS. MARKET BECOMING MORE STABLE.

THE statement has often been made that prices on honey are liable to slump after the holidays, and that it is advisable to sell as early as possible. While that is true to a great extent of Western comb honey, a change is beginning to take place. Western comb is liable to granulate, and dealers, therefore, feel that it is advisable to sell it before this takes place. But there are some evidences that go to show that the market is becoming more and more stable on extracted. While prices reach their maximum just before the holidays, honey in the liquid form will maintain its level to a great extent, not only during the early fall, but during all the winter. In early spring the prices begin to sag, in anticipation of the crop just ahead.

To a certain extent also it is becoming more and more true that Eastern comb honey is becoming more stable, the reason for this being that it is not apt to granulate till toward spring.

THE LEGISLATIVE COMMITTEE OF THE NATIONAL BEE-KEEPERS' ASSOCIATION AT WORK.

THE Legislative Committee of the National Bee-keepers' Association, consisting of Mr. W. A. Selser, Mr. N. W. Saunders, and Mr. A. T. Cook, met in Washington on Dec. 12th to consider plans for the ensuing year. They spent considerable time in discussing national legislation, but at the time of their meeting decided to concentrate their efforts toward checking the rapid spread of bee diseases in the United States. While recognizing the fact that the Bureau of Entomology, of the Department of Agriculture, has rendered splendid service by spreading information concerning disease and its elimination, they felt that the Department should go even further; and to that end the committee, by appointment, called on Secretary Wilson, head of the Department of Agriculture. First, it is asked that the Secretary give his approval to a plan for reaching every bee-keeper in the United States, and placing before him information on the subject of bee diseases; second, that he authorize the publication of a bulletin showing the relation of bees to horticulture, and, third, another bulletin on honey as a food. The Secretary gave his approval to the second and third, but demurred on the first,

as he thought the government could not undertake to hunt up every bee-keeper in the country, because it was contrary to precedent, and because of the expense it would involve. The committee believes, however, that there is a precedent to warrant this procedure, and, if so, proposes to follow the matter up at a later time.

Since writing the foregoing we have received a letter from the Chairman of the Committee inclosing one from Secretary Wilson that will explain.

Mr. W. A. Selser:—Referring to your letter of December 13, with regard to the desirability of warning farmers against foul brood in bees, I beg to state that I have ordered the preparation and distribution of two press notices—one for distribution to newspapers in general, and the other for distribution to county papers, advising bee-keepers of the danger of the disease, and referring them to Farmers' Bulletin 442 on this subject. The other suggestions you make will be considered.

JAMES WILSON, *Secretary of Agriculture*,
Washington, D. C., Dec. 20.

Apparently the special committee of the National has not labored in vain.

THE NEW CONSTITUTION OF THE NATIONAL BEE-KEEPERS' ASSOCIATION.

AT the last meeting of the National, at Minneapolis, a committee was appointed to draft a new constitution. This instrument was drawn up and duly submitted to the convention. While that body had no authority to accept or reject it, it could and did recommend its adoption by the voters at large. The latter have now formally ratified it, and the new constitution is in full effect.

The membership fee, instead of being \$1.00, half of which went to the local organization, will now be \$1.50, one-third of which will go to the local society. It was found that \$1.00 membership fee, only half of which went to the National, was entirely inadequate to carry on the work of the organization. While it may be an inappropriate time to raise the membership fee, the committee felt that the old organization could not longer continue on the old basis.

The new constitution further provides for closer affiliation with local societies, and each local is to send its own delegate or delegates to the National convention, wherever it may be held.

The new board of directors, instead of consisting of twelve members, is now reduced to five. The old number was too large and unwieldy, and the number five is small enough so that the board can meet together and thus properly plan the work of the organization.

Under the new constitution, there probably will not be another National convention before a year from the coming February.

Two cities—Cincinnati, and Washington, D. C.—are vying with each other for the next convention of the National. Cincinnati has the prior call; but Washington, whose invitation was extended later, sets up the claim that, if the convention goes to the national capital, it will have consid-

erable influence with the officials of the government, to the end that bee culture may receive further recognition, and with Congress, if it is in session, and, moreover, it can have distinguished men from the Department of Agriculture to deliver addresses at the convention. We understand that the new board is carefully considering the claims of the two cities.

ARE BEE-KEEPERS MAKING A COSTLY MISTAKE? A WARNING; MARKET PRACTICALLY BARE OF COMB HONEY, WITH A BIG SUPPLY OF EXTRACTED.

SEVERAL times during the last three or four months we have called attention to the fact that the production of comb honey was being dropped by many producers in favor of extracted. Just before he died, Mr. W. Z. Hutchinson, having observed the same fact, cautioned his readers in the *Review* not to make the mistake of going to the other extreme, adding that he feared the time would come when comb honey would be a scarce article, and the market would be glutted with extracted. The prediction has been all but verified. Now that the season is over, we are in position to know pretty nearly where all the comb honey is that is left; and we can assure our readers that the supply is exceedingly limited. The big buyers of the country are making inquiries as to where they can get choice comb honey; but aside from little lots, of inferior quality, they are unable to find any. Some three or four buyers have cornered some choice lots, and are awaiting an advance in price. There will be small lots here and there among retailers, but that will be about all. On the other hand, the supply of Western *extracted* honey appears to be large for this time of the year.

Our readers will remember that early in the season reports from the West were very slow in coming in. Many of them were misleading, and producers in some sections where, apparently, big crops had been produced were evidently holding back the fact. The reports from the West showed almost as much a shortage as those from the East. The result is, there is a big supply of Western extracted—mainly alfalfa and mountain sage; but the supply of Eastern white honey, both comb and extracted, is almost entirely exhausted.

There are two reasons to account for the great disparity between the production of comb and extracted the past year. First, breakages from shipment have disgusted many producers with the comb-honey business; and, second, the honey season throughout all the East, where comb honey is largely produced, was almost a complete failure. Eastern bee-keepers do not produce honey on as large a scale as those west of the Mississippi; and what they do produce is largely comb. On the other hand, the conditions in the West are almost exactly the reverse. Extracted honey probably forms from 75 to 80 per cent of all the honey produced.

One large buyer in the East, in talking with a representative of this journal, lamented the fact, and with good reason, that the honey reports in the bee-papers during the last year were misleading—at least so far as they related to the production of Western honey. "This has a tendency," he said, "to boost the market on all grades of honey, including extracted. The market on the liquid product began to soar, and buyers refused to purchase. Then there came the inevitable slump after prices had been boosted too high; and now the market is overstocked with extracted."

He then cited the case of a large producer of buckwheat honey who had a fair crop to sell. The general talk about the poorness of the season caused him to put his prices clear out of sight. Of course, no one would buy. He began to offer his honey at lower figures without a taker. Soon carloads of Western alfalfa and mountain sage, of a better quality, both in flavor and color, flooded the market; "and," said Mr. Commission Man, "our friend with his big holding of buckwheat would be glad to unload at any price—a sadder and a wiser man. This is not an isolated case, because some of the Western producers are finding it hard to unload."

One other buyer expressed himself most emphatically, saying, "You bee-journal fellows ought to be scored for letting some of these Western producers pull the wool over your eyes. Why don't you urge more the production of *comb* honey? If the facts as to the amount of Western honey had been given in the first place the general market would have been in much better condition."

While the bee-papers come in for a fair share of blame, perhaps, yet how are the journals going to get information when the reports of actual conditions are held back?

Referring to the first reason why bee-keepers are dropping the production of comb honey, it seems to us that almost every mail has brought some complaint about comb honey arriving in bad order, simply because it was carelessly packed. Producers who ought to know better continue to put up their goods in poorly made and badly designed shipping-cases; and, again, they often fail to ship in carriers, with the result that both producers and buyers are disgusted with the whole business. Extracted honey, however, can be shipped in barrels or cans, with comparatively little leakage or breakage. It is not injured by candying, and usually there is a fair demand for it.

But the scarcity of comb honey and its higher price should make producers wake up to the importance of producing more section honey. It will hardly be possible to get too much for the coming year. We never saw a time when fancy or No. 1 comb honey would not sell readily at good prices.

If the bee-keeper who reads these lines has reason to doubt our words, let him write in to the large markets and see how the demand now stands for comb and extracted. The fact is, brethren, we are confronted by a condition and not a theory.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

THE COLOR of honey is lighter on high lands than low; in the north than toward the equator; on calcareous than on ferruginous soils; in a wet than in a hot dry season. A peculiar fact is that a mixture of two honeys is darker than either kind separate.—*Deutsche Imker*, 308.

F. DUNDAS TODD once criticised my pictures, and I've had it in for him ever since. Now's my chance. Nine of his pictures in last GLEANINGS are bad—very bad. They're nice pictures in other respects, but he made that poor fellow stand all the while he was doing his stunts instead of giving him a comfortable seat.

CHRISTMAS was a very bright day. At 1 P.M. cellar-doors were wide open, as they had been for days, both day and night; temperature in cellar, 49; outdoors, 30 degrees. At the wall furthest from the door I read fine print—easily. Bees had been in cellar 42 days. In four minutes two bees flew out. If the room had been closed up dark I suspect more would have flown out—not because dark, but because close. The moral is that bees in a cellar that have not been confined long will stand much light *if the air is pure*. Toward spring they will not stand light so well.

THE DISCOVERY that bees eject water from nectar while on the wing was a rediscovery by A. I. Root, says Claude Deshommes, *L'Apiculteur*, p. 456, the discovery having first been made by M. Babaz in 1868. [The question has been raised whether bees ever discharge water on the wing when gathering nectar or sweetened water from outdoor feeders. It takes a little careful watching before one can see this fine spray shot out from the bees; but when he once sees it, he is able to discover it in other bees as they start out on the final flight for the hive; and while we have not absolute proof that the spray is made up of water, the facts point very strongly that way.—ED.]

ABOUT that pie. Either the printer or I chopped the head off that last Straw, p. 4, and stuck it in as the fourth Straw. No matter. You seem to think, Mr. Editor, I haven't stuck close to the text. You're right. Let's get back to it. You said moths were liable to lay eggs in S. D. House's combs or his nice comb honey after either has been taken from the hive. I supposed his nice comb honey was in sections, so I ventured the guess he never had an egg laid in them after they were taken off, since the moths don't lay eggs in comb honey here after it's taken from the hives. J. E. Crane practically says they do with him. So you'd better cut me a piece of the pie. The question now is, whether my moths or Bro. Crane's are the exceptional ones. If it's the general rule, and especially if it's the rule with Bro. House, then bring on the rest of

the pie. [It is probably true that the moth-miller is a more serious pest in some localities than in others. You of course know it is unknown in Colorado, and, if we mistake not, in all other high altitudes.—ED.]

ON FIRST READING what Arthur C. Miller says, page 755, I said to myself, "I never thought of it before; but it seems clear that those wing-stubs must hinder the queen about laying." But on further thought I recalled the thousands of queens I have had with both wings on one side cut off about half—fine layers, eggs placed regularly in cells, no vacant cells, no superseding till two or three years old, and it didn't seem possible that clipping could do so very much harm. Isn't it just possible that the queen raises her wings when about to lay, just as any other lady raises her dress when it is in the way? Wouldn't the wings of a queen show wear if they should "slide" over the surface every time an egg is laid? We know that the wings of a worker become ragged with age, and I suppose that is from friction with the air. If three or four weeks' friction of the air makes the wings ragged, would not three or four months of the greater friction of the comb make the wings still more ragged?

LOUIS MACEY, p. 734, perhaps you don't fully understand my attitude. I think my queens average as good in their second year as in their first—perhaps better. When they begin to fail, I think the bees will supersede them, whether it be in the first or the fourth year. So I don't need to supersede a queen unless she is poor, no matter what age. If others have bees that are not so good in their second year, and the bees themselves will not supersede them, that's another story. Then there's one thing you and I can't get away from: A queen in her second year is forty times as likely to swarm as in her first year. That alone may be sufficient reason for some to requeen annually. But annual requeening and improvement of stock don't go well together. [There is one fact you have not mentioned in favor of a young queen; and that is, she will lay eggs in late summer or in the fall when an old queen can be coaxed to do this only with difficulty by stimulative feeding. We would say that colonies having young queens in the fall of the year stand a much better chance of wintering through, because their hives will have a large force of young bees raised late in the season. Too many times queens stop laying after the main honey-flow; and the old bees beginning to die off leave the colony too weak to be in good condition for winter. While it is true that some old queens are too valuable to kill, we are coming more and more to believe that the average beekeeper should aim to have young queens in his apiary.—ED.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

I do not think the editor's value of drawn comb an overestimate—page 699, Nov. 15.

An unusual number of fall dandelions bloomed here in New England, the same as at Marengo, Ill., and in Canada; but they were of little value to bees.

Slowly the value of honey as a medicine is becoming known and appreciated. I am not sure but another leaflet along this line would prove of great value—p. 644, Nov. 1.

Dan White is all right about ripening honey—page 684, Nov. 15. I find that honey ripened as it should be is very difficult to strain unless warm; and even a gravity strainer will work very slowly.

I think our friend A. C. Miller is a little off when he thinks smoke from cotton will, as a rule, irritate bees, as he claims on page 664, Nov. 1. Queer, some of the rest of us bee-keepers have not noticed it.

All who wish to improve their bees can not study with too much care the article by H. D. Tennant, page 651, Nov. 1. The science of breeding (and it is a science) is becoming better understood than formerly; and those who will may profit by such an article as Mr. Tennant has given us.

Our experience corresponds with that of the editor in footnote on feeding brown sugar, page 646, Nov. 1. A few years ago we fed two or three tons of raw sugar to bees as winter food, and they wintered fairly well; but we believe the best white granulated quite as cheap and much more satisfactory.

Dr. Miller tells us that Dr. Bethune told him that a young queen could be reared and fertilized in a hive with a very old queen, page 646, Nov. 1. I believe this a very important question; for if we may rear a queen in a hive having an old one, much time will often be saved by so doing.

That metal air-spaced cover, page 699, Nov. 15, is certainly a nice thing, especially for hot sections of country, as it combines protection from rain and sun at the same time; but I should think it would prove a plaything for the wind. I have seen nothing I like better than the telescopic cover covered with metal.

Our genial friend Doolittle tells on page 650, Nov. 15, of an old man whom the bees would not sting. I have heard, during the past fifty years, of several such, but have thought such statements should be taken with some allowance; but after reading what Mr. Doolittle says, I will doubt no longer.

I wonder if Mr. Doolittle can tell us why there is such a difference in the way bees treat different people.

Arthur C. Miller tells us, page 664, Nov. 1, that when bees ripen honey they spread out all they can; but if the night is cool they go to the brood-combs just to keep their feet warm, rather than to keep their brood warm. Well! there is where we don't think alike. I still think bees care more for their brood than the warming of their feet or the ripening of honey.

We are under obligation to Mr. Holtermann for a full description of his present method of wintering out of doors, and his reasons for it, page 695, Nov. 15. Where bees can be wintered indoors perfectly, as is sometimes the case, and you have but one yard to look after, and can be always on hand to attend to it I believe there is no better way. But as cellars run, I prefer the outdoor plan; and of outdoor plans none are better than the one given by Mr. Holtermann.

THE AVERAGE YIELD PER COLONY.

On page 654 Mr. C. C. Chase tells in a letter to E. E. Colein how he secured from 20 hives and 30 three-frame nuclei 4000 lbs. of honey in "*one of the worst seasons on record*," while one nucleus with a poor queen gave him no surplus. Now, the inference one would draw, especially a beginner, is that if one only had choice queens, and gave his bees suitable care, he could do as well in the worst of seasons—which would be wide of the mark. Now, we who have been in the business longer know that, in very bad years, we get no such yields of honey, although we may have good stock and give them the best of care. On the other hand, in a good year even hives with quite ordinary queens, if given care, will give very good results. It often happens that, while one section is very poor, another may be good. The past season was, as a rule, very poor (perhaps one of the worst), yet there were isolated localities where the yield of honey was good. One such I am thinking of where a bee-keeper secured some 8000 pounds of surplus, mostly comb honey, from 75 hives, and increased to 115 colonies. It is also true that, with a very poor queen, we can not get much if any surplus, even in a good year. If there are few flowers, or even if there are many that yield little or no nectar, we can not get much surplus with the best of queens and best of bees and best of care. The estimate of the editor of GLEANINGS as to the yield to be expected from apiaries with good care, as given on page 678, is very much nearer the mark, or will give us a much better idea of what to expect, and I am afraid his estimate is a little too high for the extreme North.

Bee-keeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas

With every thing prepared and ready whenever it may be needed for the coming season, the bee-keeper who is so fortunate as to be so situated can stare the season bravely in the face and feel as though he would be sure to conquer, while the go-easy kind of fellow who waits to see if it will really pay him to get any thing ready at all has apparently no feeling at all. The former will meet with success if it is to be had, while the latter will meet with—well, to tell the truth, we can't tell.

TEXAS HONEY.

To show how great is the demand for our honey in our great Lone Star State we need only mention that the entire Texas crop was practically sold by the end of August. There were several small lots here and there after that, but they went in a hurry as soon as they were located. There was a demand for more, but no honey to supply it. The Southwest Texas crops were sold out long before this time, and the Central Texas producers, whose crop comes a month or two later, were overrun with orders as a consequence, when their product was ready for market. The writer's experience this year was almost exasperating at times, the orders coming in some mails numbering from half a dozen to several dozen. It was impossible to put up the honey as fast as it was demanded. It took from two to three weeks to fill many of the orders, and at the end of the season some which were unfilled had to be canceled, amounting to more than our entire crop of 67,000 lbs. Since that time orders have come in for more honey every week, but there is none to supply.

This is not only true of this year, but 1910 and 1909 were very similar, except that the season closed later last year. However, the number of canceled orders each year for several seasons has run up into many thousands of pounds. This is not only our own experience, but that of many other large producers.

There have been a few Texas bee-keepers who have shipped in honey from other States in the West, but not many, for our bee-keepers are prone to stay by honey produced in Texas by Texas bee-keepers, and, as a rule, do not care to supply any other. Then it is a fact that many consumers do not like to buy honeys that they are not used to. This is especially true of honey with a decided flavor, such as the western alfalfa. Of course, some customers do not mind a different flavor, but on the whole we know from personal experience that a preference for the Texas honey does exist.

It would be interesting to know just how much honey is annually produced and consumed in the Lone Star State. We know that the output is enormous, but we have no reliable statistics to show what it is at

the present time. One fact exists, that the greatest bulk of this honey is consumed right here at home, and very little of it finds its way into the Northern markets. Oklahoma also is a great consumer of our product. This is due to the fact that, on the whole, that State and all of the northwestern portion of Texas are not adapted to bee-keeping except in a few favorable localities; and the consequence is, the honey must be procured from Central and Southwest Texas. The consumption of honey is great in both Texas and Oklahoma, the main product being bulk comb honey, which has for many years been strictly a Texas product.

FIELD MEETINGS IN TEXAS.

It seems that the Texas bee-keepers have been so busily engaged with their extension of apiaries and the business end of their following to such an extent that no time remains that could be profitably spent in gatherings or conventions and field meetings of bee-keepers at various times during the year. Why this is, we do not know. Texas had at one time as many as eight bee-keepers' associations; but there is only one to-day, and that is not as lively as it used to be. There is something wrong somewhere, whenever those who are engaged in the same line of work neglect the social side of their vocation as found in the conventions and other gatherings.

Texas is large enough to have half a dozen bee-keepers' associations, even if some of them be small in number. Nothing can do more good in furthering the progress of the industry, and nothing brightens up and helps the bee-keeper more than getting away from home and his work occasionally and rubbing up against some of his fellow-men who are engaged in the same calling. This is one thing that should receive more attention on the part of the bee-keepers of the big Lone Star State; and to start the ball rolling, and to begin the new year properly, the writer will be glad to hear from every bee-keeper in the State who is interested in having, at some early time, field meetings or similar gatherings of bee-keepers, at which important topics pertaining to the industry may be discussed. If too busy to write a letter, a postal card will do if the name and address are plainly written.

It may be well to take this opportunity to state that the writer received some time ago the appointment as Consulting Apicultural Expert of the Texas Department of Agriculture, at Austin, and all correspondence may be sent there if desired. All persons desiring information about bees or bee-keeping may obtain it by writing to the State Department of Agriculture. Hon. Ed. R. Kone is the Commissioner of Agriculture of the Department.

BEE-KEEPING IN CALIFORNIA

P. C. CHADWICK, Redlands, Cal.

Before beginning outdoor feeding, take a look over the yard to see that there is no robbing in progress.

Light rains followed by cold, heavy, drying desert winds describe the weather conditions so far this season.

E. M. Gibson's scheme for avoiding lifting, page 721, Dec. 1, is good; but I think mine is better, for a full super never need be lifted. I will give details later.

In the sixth item of my notes in the Dec. 15th issue I meant to say that the Tremont yard is 600 feet *above the oranges*, at an actual elevation of 2600 feet, since the oranges are 2000 feet above sea-level. In flying the three miles, therefore, the bees have to ascend 600 feet, or 20 feet to the mile.

Mr. C. H. Miller's account of the swarm of bees flying 15 miles over the desert is probably correct; but it is not likely that this distance was covered in a single flight. It is more than probable, however, that their present home was located by scouts at some distance from where they took up the last leg of their journey to it.

Quoting from p. 1021 of "Honey-plants of California," "The sage-worms in cloudy weather often become abundant enough to destroy much of the bloom." It has been my observation that they are most abundant in off seasons when the sage is less thrifty; but I have never observed that the weather had any influence, and am of the opinion that it does not.

I have never known an instance where a comb was mutilated by bees in order to afford room for drone comb, page 516, Sept. 1. They always manage to build enough drone cells between the top-bars and excluders; or, if no excluders are used, often utilize the space between the upper and lower frames. If they made a practice of cutting out comb to provide room for drone-comb building the value of foundation would be somewhat less.

What would become of our great citrus-fruit industry if the growers used no more system in marketing than we bee-keepers do our honey? Do we not possess brains enough to form a marketing organization for our product? At least we need an information bureau to issue bulletins informing bee-keepers of conditions, prices, etc. As it is, we harvest our crop, sell it to the first buyer that comes along, at what he may offer. I have known buyers to pay three different prices in Redlands, on the same day, for the same grade of honey. That is business! We can not blame the

buyer for his shrewdness; for so long as we continue to be dupes we may expect to be duped.

Every one with whom I have talked or corresponded on the subject of more stringent foul-brood laws agrees that such a law would be an excellent thing—for the other fellow; but few are willing that it should apply to *them*. If this should be the general sentiment, the fellow who thinks he does not need inspecting will, very likely, wake up to the fact, sooner or later, that he has some neighbors who need it, and he will have no recourse but to sit and wait until his neighbor is cleaned out.

The Dec. 1st issue was the most interesting number of the year to me, inside and out. The cover picture, taken at Liberty, Mo., less than 40 miles from my old home, where I spent 18 years of my bee-keeping life, is a most beautiful one. I can imagine rabbit-tracks crossed and crisscrossed among the hives. Inside I find Doolittle's excellent article on excluders—one of my hobbies (if I have any)—a hobby, because it is only in recent years that I have learned its true value, and I will preach excluders as long as the present hive and system of management are used. I have neighbors who do not use them, and argue that, when the bees need room, they will crowd the queen down. That is true to a degree; but crowding should be avoided, for it causes loss of time. Besides, it takes 21 days from the egg for a bee to hatch; three full extractings are often gathered in that time by a colony, which goes to show that the brood does not get out of the way fast enough. I prefer to let the queen go where she may until two or three weeks before extracting time; then put all the brood down that you can get down, and put on the excluder.

Mr. E. M. Gibson's comments, p. 721 on decapitating brood, are sensible and to the point. They pleased me very much.

Elias Fox, speaking of bee-trees, page 731, touches a subject dear to my heart; for of all pleasures of my boyhood days (and I am not over it yet) I believe hunting bee-trees was the greatest. Did it pay? Financially, no; in pleasure and recreation, it was one of my greatest assets. I can not agree with Mr. Fox about penalizing for robbing a bee-tree and killing the bees—that is just what should be done where foul brood is prevalent.

California bee-keepers should apply to the Interior Department for permission to enter forest reserves and remove bees from trees, especially in infected areas. While driving through a forest reserve in San Diego Co. I counted nine bee-trees, from the road, while traveling a distance of two miles. They were all in hollow and decaying live oaks that were of no actual value—most of them in limbs that could easily be removed.

Conversations with Doolittle

At Borodino, New York

BEEES IN THE MIDST OF BLOSSOMS.

"I must move in the spring from where I am now located, and wish to do the best possible with my bees. I should like to locate from one to two miles from where the greatest profusion of honey-producing flora abounds. It will be quite an inconvenience to me to be located in the midst of this bloom; but if the income from the bees would be enough greater to pay for that inconvenience, then I might persuade myself to locate there. Will you please tell us just what you would do under these circumstances?"

"This is quite a reasonable question for any one to ask who intends to locate an apiary, but who himself desires to be in a small town or other place not right in the midst of a good nectar-producing locality. A location in a valley full of honey-producing flora, together with rising hills on either side, covered with all manner of nectar-yielding flowers clear to their summit, two to five miles away, would be an ideal location for one who keeps bees for a living. But as it is impossible for all to enjoy such a location, and as other environments are likely to have a bearing on the decision, such as a convenient school for our children, or a business for some of the family, it is often best to accept the situation as it comes to us. And I do not think that a distance of one mile from any profusion of nectar-producing flora would make difference enough to be noticeable. I once heard the claim at a bee-convention, that a colony of bees which has to travel one or two miles from home for their stores will soon become so depopulated that the result in honey is not half that stored by colonies set right down in the midst of bloom. Another claimed that the loss of time from the young field bees in hunting for nectar one or two miles from home is almost sufficient to turn success into failure. Another, that it stands to reason that less time is lost in getting the whole force at work on the honey-producing flowers where the latter are plentiful all about the hives than if the pasture is one or two miles away.

"Probably no one can tell definitely about these matters without testing a number of colonies right in the midst of the blossoms, and an equal number one or more miles away, and repeating the test for a term of years; and as I have never done this, I can not be considered as an authority in this matter. I can only give my experience, which can be taken for what it is worth. All of my experience goes to show that those who argue that bees must be set right down in the very center of the honey-producing flora do this more from theory than from actual knowledge. I am led to believe that there would not be difference enough in the results, at the distance named, to pay for moving the apiary up to the bloom during

the time of the blooming of the flowers and back again for the rest of the year.

"The flight of bees must of necessity cover a vast area. No one, two, or three acres would give an apiary of 50 colonies even a living. I am often reminded of what a man once said to me about my bees in connection with my mother's flower-garden of about one-eighth of an acre. We were looking at a crop of about six thousand pounds of section honey I had piled in the honey-room. 'Oh, what a pile!' he said. 'No wonder your bees do well when your mother has such a pretty flower garden as I always see in bloom when I pass.' Of course, these flowers were 'right under the noses' of my bees; but not one out of ten varieties even attracted the bees; and when basswood was in bloom five miles away, not a bee was to be seen on any of these flowers; yet the sections were being filled as if by magic.

"If the flight of bees were as slow as the walk of a man, then the reasoning of our 'right in the midst of flowers' men would be more logical. I have watched our great 'Empire State' express train on the New York Central R. R., running at the rate of a mile a minute, and it passed my vision at no more rapid rate than the bees do over the hill on a still day when working on basswood from two to five miles away.

"If my questioner could see how the combs grow in the sections, the whiteness of the honey, and the beautiful cappings, as I have done when there was no open bloom of the basswood within three miles of the apiary, I think he would incline, and all the readers of GLEANINGS as well, to the same opinion I do; namely, that the so-called necessity of a short distance to the flowers, in order that success may be obtained, is little short of a myth. From many observations during apple and clover bloom I am convinced that bees go from one to three miles from home for nectar, from choice, during the summer months, during which months the larger part of the storing of honey is done, as I have seen thousands of Italian bees working on these different blooms three miles from where any Italian bees were kept, with a profusion of these blossoms all about the Italian apiary and the intervening space between.

"I have seen good crops of buckwheat honey stored when there was not a field of buckwheat in sight of the apiary, and only one field of about 12 acres within less than two miles, while hundreds of acres were white from three to five miles away. These experiences, together with having tons of basswood honey stored from the tops of the high hills from four to seven miles from my apiary during the past 40 years, lead me to feel safe in advising you to locate at the place you say will be the most desirable, rather than to inconvenience yourself by setting your apiary down in the midst of the bloom."

THE ISLE-OF-WIGHT BEE DISEASE.

A Serious Disease of Mature Bees that is Doing Much Damage in Parts of Europe; an Entire Apiary of 160 Colonies Destroyed.

BY D. M. MACDONALD.

All other bee-diseases sink into insignificance in their ravages when compared with this insidious and malignant trouble. They can be fought against and overcome. We know their true origin, the nature of their development, and, from patent signs, can diagnose their presence, while preventives can be applied to check their spread or exterminate them. Like the pestilence, however, this new disease walketh in darkness, its conception and incubation come like a thief in the night. Its origin is uncertain.

In 1904 reports emanated from the Isle of Wight regarding a mysterious malady afflicting bees, virulent to an extreme, and deadly in its destructiveness. In fact, bee-keeping was quite wiped out in this lovely island by the season of 1908. Worse still, that year reports reached our journal, showing that distinct symptoms were manifesting themselves in various parts of Hampshire. That and the following season saw whole apiaries affected—several so seriously that they were exterminated. Outside the infected area bee-keepers were inclined to minimize matters at first; but soon alarm spread when it was realized that, as a consequence of the dissemination of swarms from the infected area, the disease had spread in 1909, not only to the southern and mid-land counties but also to the north of England and even to Scotland. Even then the deadly nature of the malady was not fully realized, and combs from infected hives were freely inserted into colonies hitherto immune, while swarms and driven bees were hived on the works whereon bees had died. Consequently the disease spread. The infection, too, passed on from hive to hive. The fell destructiveness may be guessed when it is stated that in one season an apiary of 160 colonies had every hive empty. Another, the other day, was reported to have 84 out of 86 all dead. Thousands of such specimens could be given. Some claim that treating the bees by shaking, as in a case of foul brood, and compelling them to work out new combs, will cure. Others go to the other extreme and maintain that healthy bees may be run on the diseased combs and continue healthy. Practical experience during the last three years convinces the writer that both claims are fallacious. Time and again both plans have been tried, only to end ultimately in failure. All recommendations have been tried, but none have proved fully effective.

The best advice that can be given in the light of our present knowledge is to destroy every thing movable in the hive; singe

the interior effectively, and thoroughly disinfect every thing. Dig the ground all around and bury or burn every bee seen lying about. Even then a new start should not be made on the same ground if it is possible to secure a fresh site.

As a sample of the rapidly destructive power of the disease, stocks as powerful as they could be in early June, this year went down so rapidly that, instead of filling ten frames and three supers, they deserted all but the lower crate a month after infection, in spite of splendid breeding; and at first it appeared that every egg laid came to maturity, for it must be remembered that, unlike foul brood, this disease does not affect the larva pupa nor even the perfect imago. It seems evident, indeed, that it is only when bees go out as foragers that the workers are infected. Breeding all July, during the delightful summer weather experienced, went on apace, and for a time hopes ran high that the colonies might work out their own salvation; but these hopes were dashed to the ground when, in September, on return from holidays all were found dead or dying. The miserable plight of the remnant was deplorable. Worse still, neighboring hives all around showed the well-known symptoms, and now most of those left are dwindling rapidly in spite of all attempts at cure. Earlier destruction would have been a kindness!

The symptoms at first are indistinct, so that the scourge has a deadly hold before any very clear signs are patent. A marked decrease in the number of bees occupying surplus chambers shows something is amiss; fewer bees go out foraging; even the bees which are apparently healthy show a disposition to loiter about, and exhibit a disinclination to go to the fields. Therefore large numbers are found lolling about on the flight-board—so much so that on a fine day it is black with them, as if they were in need of more room overhead. An examination of the top super, however, shows it quite deserted, owing to lessening numbers.

On close inspection an odd bee at first is seen flying aimlessly about. It or others may be seen crawling on the ground near the hive, making ineffectual attempts to fly. Looking more closely the wings are seen to make futile efforts to buoy the insect up into the air. On examining these bees it will be found that, generally, one of the small wings (almost invariably the left) may be seen sticking out at an angle above the front wing in an unnatural way, and looking as if it were dislocated. These bees then crawl about aimlessly, dragging their legs in a crippled way. They congregate in small clusters, numbering from half a dozen to a score, as if seeking mutual warmth. Many of them make feeble attempts to climb up any vegetation growing near, but after a time they fall down to die. While crawling about, the abdomen is heavily de-

pressed. It appears of abnormal size, and drags as if too heavy to be fully supported. In this advanced stage of the disease the interior of the hive, if examined, shows a sorry spectacle. The bees display none of the well-known energy so markedly symptomatic of a colony in full health during the active season. Breeding is, however, encouraged to a late period; but with the decreasing numbers it wanes until at last queens are entirely neglected and cease to lay. Then the rapid diminution of the numbers is most marked.

Examining a diseased bee, even with the naked eye, the abdomen appears abnormally distended. The bee seems unable to support the heavy burden caused by the excess of fecal matter. This, under the microscope, is found to consist largely of undigested pollen-grains, particles of wax, and the usual excrementary matter; and here we have a very large number of bacteria. On removing the digestive organs the colon is found abnormally distended, and the contents are very varied in color, smell, and substance, these features differing very considerably according to the season of the year. During summer time, tops are heavily spotted with a thin bright-yellow eviction. At other times it is drier and browner, while in winter and spring bees void a foul, brown, evil-smelling excretion over all the combs, frames, and the front inner walls. Here is, undoubtedly, the source of infection in many cases, when the trouble once finds a lodgement, for all this fouling contains a prodigious number of infective bacteria ready to be carried by robbers to all surrounding healthy bees. The hive, interior and exterior, as well as all the surrounding area, is, in fact, a hotbed of infection.

The trouble may break out in a hitherto healthy colony at almost any time of the year. During such a fine summer as we enjoyed this season, the bees battled long with the ailment, keeping it at bay by rapid breeding; but in winter and spring, with scant numbers present they dwindle rapidly and soon die off.

Innumerable causes have been guessed at in the past, but full investigation exploded the numerous theoretical conclusions. Many cures, too, have been suggested, but none have proved thoroughly effective; so that the originating cause and the true cure have yet to be discovered. It is an undoubted fact that many of the symptoms appearing on the surface are very similar to those which manifest themselves in May pest, malignant dysentery, paralysis, and *Nosema apis*. Indeed, the latest conclusion come to by Dr. Malden would lead to the decision that all of these may resolve themselves into kindred diseases. If so, the painstaking investigations of Drs. Zander, Burri, Maasen, Phillips, Malden, and others, may aid us in solving the problem. The remarkable series of about one hundred studies of *Nosema apis*, by Dr. Zander, should be a priceless guide to other students of this disease.

Whether the inciting cause or not, the latest anatomical investigations in this country reveal a prodigious number of these protozoöns in various stages in the cell lining of the alimentary canal, and particularly in the colon of many if not most bees suffering from this disease. Our lethargic government Department of Agriculture has at last taken up the subject of bee diseases, and hopes may be entertained that the long and painstaking investigations now going on may soon bear some fruit, as a result of which the disease may be successfully battled with and overcome.

Banff, Scotland.

MY EXPERIENCE WITH SUPPORTING FOUNDATION TO PREVENT BUCKLING.

A Combination of Wires and Splints Gives the Best Results.

BY CHARLIE BROWN.

When I began bee-keeping in 1901 loose wiring was advocated; that is, using wires not tight enough to sing. They were expected to go down with the foundation, but I found that combs so wired would be badly stretched along the top part, and also that, while new, they were much inclined to break along each wire while being extracted. I concluded that such a way of wiring was useless, and some older bee-keepers told me that all wiring is useless; so for some time I did not wire frames at all. However, in 1909, during the honey season we had a few days of extremely hot weather. I had given the bees a great deal of foundation just previous to the hot spell, and a great many of the newly drawn combs went down altogether, and nearly all of the rest were badly stretched along under the top-bar, and buckled out of the frame at or near the bottom. (These combs were built out in the supers.) Scarcely any of the combs that I had built that season were fit to put into the brood-chamber. That convinced me that combs need support.

Next I tried splints as per Dr. Miller's plan, putting them on the foundation out of hot wax; but I found that the bees would gnaw at them where they came to the bottom, following them up, and in many cases ruining the comb; also that the foundation (medium brood) would sag and buckle in between. I next tried shorter splints, letting them come within an inch or an inch and a half of the bottom of the foundation. Bees do not seem to be inclined to gnaw short splints, but the combs near the bottom would be badly buckled in and out.

Last season I did considerable experimenting with wires and splints together; and with four tight wires and four splints I got combs good enough, I think, for all practical purposes. Three wires and four splints did not give me good combs. Four tight wires alone let the combs stretch at the top and crush near the bottom; and right here let me say that I had the wires as tight as I could get them, having driven some 3/4-inch

brads into the edge of the end-bars right by the piercings. When the wire cuts into that brad it can go no further, and one can get them so they will sing and stay tight. Of course it is some trouble to drive a brad into the end-bar by the side of each piercing; but it is much quicker and better than driving nails through and then bending them into a hook with pliers, as I have seen some bee-keepers do. Of course you have to be careful to get the brad on the proper side of the piercing; but that is no trouble after you get accustomed to the work, and you can put them in much faster than you would at first think. I do not mean to say that the wire brads are absolutely necessary; they merely help to keep the wires tight.

To sum up, I would say that, for a frame that is square or nearly so, such as $11\frac{1}{2} \times 11\frac{1}{2}$, six tight horizontal wires will result in nice straight combs. Five will not. No splints are necessary. For a frame like the Langstroth, where the wire has such a long stretch. I shall continue to use four wires and four splints until something better is devised. I have not tried it, but I believe that five tight wires, equally dividing the space between the top and bottom bars would give good combs if they were built out in the brood-chamber. I do not think we can get perfect combs built on foundation; but we want them so nearly perfect that a queen can lay a worker egg in every cell if she so desires. I confess that I do not like the splints, and am wondering whether a little heavier wire, say 28, would not render them unnecessary. Possibly some one has tried it, and can tell us about it.

Right here I want to leave my subject long enough to say that I think that what we call the Madary top-bar out here is a thousand miles ahead of your wedge and groove. It has about a quarter of the under side of the top-bar sawed away, and the cleat is kept to put the foundation in with. You put your splints in flush with what is to be the top edge of the foundation, and then nail it in, splints and all. My experience with wedge-and-groove top-bars leads me to agree with that man who some time back hit them such a hard smash.

Piru, Cal.

[You will find that H. E. Thayer has been using baling-wires in place of splints with very satisfactory results. See page 554, Sept. 1st issue for last year.

The form of top-bar put out by Madary was first advertised and sold by E. Kretzmer, of Red Oak, Iowa, some years ago. There are many who prefer it.—Ed.]

OUTDOOR WINTERING IN WEST VIRGINIA.

Fifty Pounds of Honey Required.

BY W. C. MOLLETT.

I notice that most bee-keepers in the Northern States give the amount of honey necessary to winter a colony, either in the open air or in a cellar, as from 15 to 30 lbs.

Now, this locality is not very far south, and it would be necessary to double the above figures in order to be sure of enough stores for successful wintering. Of course, all the bees in this latitude are wintered in the open air, as the cold is neither so lasting nor severe as in the Northern States. As a rule, bees can fly every few days through the winter, and it is not common for them to be kept in by cold more than 10 or 12 days at a time. Very often they will begin to carry in pollen in January or February, and begin rearing brood. It is for this reason that they require a much greater amount of stores than in the North. I have sometimes found several combs containing brood the first of February; and by March 20 they are sometimes strong enough to swarm if the season permitted it; and I have had swarms come out in April. As there is no nectar to gather until May, it is surprising how fast the honey in the hives is used up. I have had colonies that had every comb in ten-frame hives as full as they could be in October, and yet they would be upon starvation in April. Estimating each comb to hold 5 lbs. of honey, this would be a consumption of at least 50 lbs. If it requires as much more in proportion in the States to the southward, it must require at least 75 lbs. in such States as Alabama and Georgia; but as the honey-flow would naturally come earlier there, this would offset this to a considerable extent. As a rule I would estimate that twice as much honey is necessary in outdoor wintering as when they are wintered in the cellar.

FRAMES HARDER TO HANDLE, AND SWARMING WORSE WHEN THE DANZENBAKER HIVES ARE USED.

Three years ago I was induced by the favorable reports to transfer my bees into Danzenbaker hives, as they were highly recommended for the production of comb honey. I thought that, as I produced only bulk comb honey, they would be just the thing for my use. Of course, on account of the difference in the size of the frames it was a somewhat difficult task to transfer them. After I had them put into Danzenbaker hives the first trouble I struck was the difficulty in handling the frames; and as the colonies became stronger the job became more and more difficult, until it was almost impossible to handle frames without killing bees. I had never realized until then the advantage of the Hoffman or Langstroth frame as to easy manipulation. I saw then that I could handle the frames of two Langstroth hives easier and quicker than I could one Danzenbaker. When the honey-flow commenced, the bees commenced swarming; and they kept it up right along all through the honey-harvest. In strict justice to the Danzenbaker hive it is only fair to say that I secured about as much honey as usual, and it was very nice honey—possibly a little better appearance than usual. But I was glad to go back to the Langstroth or dovetailed hive, and did so just as soon as I could. Since then I have secured about the same amount of honey with not half the

trouble, and I would not use the Danzenbaker hive if I could get them free of charge; and I am firmly of the opinion that those who adopt them are making a serious mistake. The bees also have to be fed in the fall or spring, as the hives do not hold as much honey as the standard hive, and this makes more trouble.

Stonecoal, W. V., Nov. 25.

JAMES HEDDON—BEE-KEEPER, INVENTOR, JOURNALIST, AND BUSINESS MAN.

Some Unwritten History.

BY E. R. ROOT.

Little did I think, when I recorded the death of four prominent men whose names began with H, in our Christmas issue, page 743, that there was still one more whose name also began with H. The last mentioned was James Heddon, who died Dec. 7 last. First there was Hutchinson, then Hilton, Herlong, Hall, and now we add to the list Heddon. Besides the fact that all of their names began with H, it is also significant that three of them lived in Michigan. We hope the year 1912 will not take away so many of our leading lights.

Twenty years ago Mr. James Heddon, of Dowagiac, Mich., was one of the most brilliant lights in all bee-dom. Sometimes erratic, he often surprised us by his genius. He certainly was a man of many parts and varied ability.

At one time he had between 700 and 800 colonies of bees, and he made them pay, as he did every thing he undertook. He was a practical bee-keeper, and from the year 1875 up to 1890 he was a more or less frequent contributor to the bee-journals. His style was clear and clean-cut, forceful, and, on occasions, caustic. Many of his sayings were epigrammatic. He was not a man to follow in the beaten tracks of others, and we therefore find him striking out into new fields in practical apiculture. In short, he was original if he was any thing. This very independence of action often led him to differ radically with his brother bee-keepers in regard to methods and appliances.

As I look back over those old days of 25 and 30 years ago I see him as if it were yesterday. I see him telling of a short way of transferring from box hives to modern hives—a method that has come to be known as the "Heddon short way of transferring" in our text-books, for indeed it is now the method most used by practical bee-keepers. I see him exploiting his pollen theory—a theory that has not been vindicated these later years. I see him explaining a method for controlling after-swarms—a method that has also been accepted in our text-books. Again, I see him recommending flat covers, and hives without porticos, eight-frame rather than ten-frame. Closely identified with this hive was his slatted break-joint honey-board—a device that entirely eliminated the brace-comb nuisance. We still find

it in the form of the wood-zinc honey-board; but without the zinc it gave way to the thick top-bar in brood-frames. When reversible frames were the fad in 1884 Mr. Heddon brought out one of the best reversible frames invented, and paved the way for the alternating of shallow frames, and now we see him in 1885 bringing out his divisible-brood-chamber hive, around which centered so much (I might say bitter) controversy between 1885 and 1890. If ever a hive was praised and smashed all into smithereens by friends and enemies it was the Heddon divisible-brood-chamber hive. The discussions in those days regarding this hive would fill a good-sized volume. Part of it related to the practicability of the invention, but more of it had to do with its priority and the validity of the patent covering it. While it looked at one time as if the hive would sweep every thing before it, because the idea of "handling hives" instead of frames, and alternating whole brood-sections of frames instead of reversing frames individually looked particularly attractive, the divisible-brood-chamber principle, while still favored by a few who still use it, likewise reversible frames, has all but disappeared from the apicultural horizon. *Requiescat in pace.* I hope the apicultural world will never again see such an "irrepressible conflict" as followed the introduction of the divisible brood-chamber and reversible frames. It is so fresh in my mind because it was at the very beginning of my editorial management of this journal.

On p. 645 I referred to his early idea of extracting honey from combs without opening hives.

In later years I see Mr. Heddon advocating the slip-gear for honey-extractors. Whether he was the first to see the advantage of an arrangement that would allow the propelling part of the extractor to become disengaged from the reel, I do not know; but I do know that the principle has been applied to all modern honey-extractors except the cheapest.

During the latter part of the '80's Mr. Heddon was editor of a bee-journal which was a supplement to his paper, the *Dowagiac Times*. In this Mr. Heddon thrashed his opponents to a finish. During the early part of the '80's he brought out his book, "Success in Bee-keeping." This attracted considerable attention at the time, principally because of its advocacy of new principles in hive construction. The book is now out of print.

Later on we find Mr. Heddon entering the field of civic affairs, during which he became mayor of Dowagiac, and editor and proprietor of the chief organ of his party, the *Dowagiac Times*. During all this time his interest in bees continued to be unabated until the latter part of the '90's, when he seemed to drop out of apicultural matters entirely. A little later on he became the inventor of a new kind of minnow bait that seems to have been a great success. The Heddon Bait Co. is still doing a big business.

As a bee-keeper Mr. Heddon could and did look ahead of the most of us. Indeed, I think I never ran across a man who could catch on to a new trick of the trade quicker than Mr. Heddon. While not all of his ideas panned out as he hoped for, he left his strong personal impress on the apicultural world, and bee-keeping literature for years will contain much of the name of James Heddon, because he was a great bee-keeper and a promoter of ideas that still hold sway. Very few men who have risen to prominence in the apicultural field could ever be called a genius; but I think we can say, without fear of successful contradiction, that, if there ever was a man who deserved that title, Mr. Heddon was the one.

JAMES HEDDON.

Mr. Heddon was, perhaps, misunderstood by some of his opponents in discussion. He appeared at times to be like the gladiator of old, who, when his opponent was down, seemed to have a ghoulish glee in sticking the knife in deeper and giving it a twist. This was a mistake, as the following incident, perhaps, will illustrate. At first I thought I would not tell it; but as it shows another side of Mr. Heddon's character I think it ought to be told.

During the days of the "irrepressible conflict" of which I have spoken, there was a war of words between myself and Mr. Heddon over the priority of his invention which I think now was, in part, at least, unjustified, because it might encourage some to trample Mr. Heddon's moral rights under foot. I contended, as an examination of his claims will show, that his patent, granted Sept. 29, 1885, was very narrow in its scope; that it did not cover the *general principle*

of the shallow hives or divisible-brood-chamber hives, and that, therefore, he had no more legal right to claim *all* divisible-brood-chamber hives or shallow hives than a squatter on a quarter-section of land had a right to claim the earth; that his patent was limited to the use of closed-end frames in a close-fitting brood-chamber in combination with thumb-screws; that a divisible-brood-chamber hive without any one of these elements to complete the combination were free to the public. He naturally concluded that this argument, advanced by me, meant that we, as manufacturers of hives, had in mind putting a divisible-brood-chamber hive on the market that would *evade* his patent; and I confess that that would be a natural inference. But that thought was not in my mind; and the subsequent history of our business shows that we did not put any divisible-brood-chamber hive on the market until after his patent expired, as we felt that Mr. Heddon had certain moral rights; and that if, in these later days, he had shown that the divisible-brood-chamber hives were labor-savers, it would be but fair that we respect those rights.

Well, it was during this discussion that Mr. Heddon felt that A. I. Root was about to purloin his moral rights because he could do so on account of the legal limitations of his patent. Smarting under this sense of wrong, I remember particularly one bitter letter that he wrote and addressed to my father and me. Father then was very sick with fever, and we did not think he would live. I replied something like this:

Mr. Heddon.—Your letter reaches us just as my father seems to be at the point of death. I have neither the heart nor inclination to reply, any further than to say you have surely misunderstood the attitude of both of us in the matter.

Back came the quick response, or as soon as Uncle Sam could deliver the message, in the shape of a letter reading about like this:

Dear Mr. Root.—I sincerely beg your pardon. I did not know your father was very sick. I desire to recall what I said—every word of it; and I assure you that, if you mean what you say, I will say no more.

While these may not have been his precise words (for remember that was over 20 years ago) yet they convey the thought. Mr. Heddon, true to his word, never referred to the matter again, and the hive question, at least, was settled for all time.

My only reason for repeating it here is to show that Mr. Heddon had a big heart when the heart-strings were touched.

Moral.—We often fight over something that we fancy has extraordinary value when it has not. The divisible-brood-chamber hive or the shallow hive was thought to save half the labor in handling bees. It has been tried in the balance of Father Time, and, except in the hands of a few experts, has been found wanting. Think of the pages upon pages of printed matter, to say nothing of the volumes of correspondence and time that was wasted. Think of the ill-feelings and misunderstandings that might have been avoided.

FIG. 1.—Marchant's home yard of 400 colonies. Along the Appalachicola River as many as 500 colonies can sometimes be supported in one yard. He has had as high as 600.

BEE-KEEPING ON THE APPALACHICOLA RIVER.

Something More About that Wonderful Honey Country; the Extent of the Tupelos; the Suwanee River, Famed in Song; Orange-growing Successful in Northern Florida where it Often Freezes Hard.

BY E. R. ROOT.

In our Dec. 15th issue I told something about the wonderful Appalachicola River, a region where nearly 2000 barrels of honey has been produced in a single season from an area that is smaller, I venture to say, than almost any other area that has produced only one-fourth of that amount of honey. Our friend A. B. Marchant, at Marchant's Landing, where I showed that big row of barrels on page 753, is almost in the heart of this wonderful bee country along that remarkable river, fringed as it is with the honey-bearing tupelo.

In this connection permit me to say that, so far as I can ascertain, the tupelo grows along the banks of all those rivers of Northwestern Florida, including the Suwanee River, made famous by that song that for many years has charmed millions and millions of people. If it is true that the tupelo and the gallberry grow in these regions it is a wonder to me that bee-keepers of the country have not known more about this territory before; and it is a greater wonder to me that Northern people should be flocking to the north and east coasts of Florida, where most of the lands are poor, when the soil in Northwestern Florida, at least along these rivers, will grow practically any thing and every thing. For the last few days I have been eating oranges sent me by my friend Marchant, near Marchant's Landing. When I saw his beautiful orchard where he had taken off time and again from 1500 to 2000 boxes of oranges, I said, "Why, I didn't suppose you could raise oranges as far north

FIG. 2.—Another view of the home yard, showing the extracting house.

as this. I supposed that the heavy freezing that you get here from time to time would utterly destroy the trees."

"Nonsense! It is a little more work and care, but we think our Northern Florida oranges are much sweeter," he said. "Hard freezes years ago did us damage, but we have profited by experience."

Here was an orchard 12 years old that has stood all kinds of freezes. Indeed, I understand that the man who knows his job, the soil, and the locality, can select a variety that will stand hard freezing, and, what is more, he can work the scheme of outside furnaces that are employed successfully in the more southern portions of Florida to keep off light freezes. The oft-repeated statement, that oranges can't be grown successfully above the freezing-line, is a joke according to these northern growers. But I will have more to say about this at another time.

Let us now look over Mr. Marchant's apiaries and his hive-stands. First, Fig. 1 shows a general view of the home yard of 400 colonies. Just think of it! 400 colonies in one yard year after year! That shows what the tupelo can do. Fig. 2 shows the same yard from a different angle, taking in the shop and the honey-house where the extracting is carried on. This yard is located close to the boat-landing that I showed you on page 753, Dec. 15. When the barrels are filled with honey at the extracting-house shown at the extreme right, Fig. 2, they are rolled down to the wharf and finally put on the boat. They are then carried by water clear to the city of New York at a freight rate of only 38 cts. per 100 lbs.

"Why," said I, "Mr. Marchant, you fellows down here have a snap. You are clear off in the woods, in a country that is not overstocked, and yet you are almost next door to one of the biggest cities in the world—New York."

The secret of it is, there is the Appalachicola River deep enough for big boats open-

FIG. 3.—Marchant's hive-stand.

ing up into Appalachicola harbor, then into the Gulf of Mexico, and finally into the Atlantic. By glancing at Figs. 1 and 2 you will see the tupelos in the background right along the edge of the river bank. These trees, together with other gum-trees, skirt the edges of this stream for over 100 miles. Emptying into the Appalachicola are dozens of other but smaller streams. Up one of these (what is known as Owl Creek) Mr. Marchant has another yard of about 400 colonies. In fact, I could imagine that dozens of yards could be located clear up along this river and its tributaries without any danger of overstocking, simply for the reason that the country is so new, and that the great mass of bee-keepers have never known of this wonderful territory where such beautiful white honey that does not candy is produced by the shipload.

But the question is asked, "Why are there no more bee-keepers and bees along this river if all you say is true?"

¶ Largely, I understand, because it is difficult to find a good spot to put an apiary on

ground above high water, and then malaria and mosquitoes are prevalent in many places along the river. In our next issue I will give you some snap shots showing whole apiaries on the river, located up on stilts.

But let us go back to Mr. Marchant's home yard. We notice that his hives are put up on high benches. This is not on account of high water, but for convenience in working and to avoid harboring-places for ants. We observe, also,

FIG. 4.—Marchant's scheme for weighing his honey with a large pair of steel-yards and grab-hooks.

FIG. 5.—A closer view of the grab-hooks for catching the barrel while it is being weighed.

that the grass has been cleaned off so that the ground is level like a brickyard. In front of every hive is a board running from the ground clear up to the entrance. Notice Fig. 3, which shows the details of the hive-stand as they are made at the Owl Creek yard. This cleaning off all the grass is largely for the purpose of keeping away ants that are so destructive in most localities in Florida. Mr. Marchant thinks there will be no trouble from this pest provided the ground where the apiary is located is kept free from all boards, rubbish, vegetation, and shrubbery, including trees where the ants are apt to form their nests. Later on I will show you something how these ants make nests in trees, and what fine chicken feed they make.

MARCHANT'S UNIQUE SCHEME FOR WEIGHING HIS HONEY.

Let us now step under the shed in front of Mr. Marchant's honey-house, shown in Fig. 2. Here we see a mammoth pair of steelyards; and connected with them is something that looks like ice-tongs. See Figs. 4 and 5. This scheme for weighing honey in barrels by means of big steelyards beats any thing else I ever saw. They cost only \$3.50, and then all that is required is a long pole, a support overhead, and an iron ring having attached to it two iron rods with hooks on the end.

We will say we are now ready to weigh up our honey. One man steps over to the end of the long pole; the steelyards are attached while the second man rolls the bar-

rel under the pair of iron hooks. The steelyards are dropped down until the hooks catch over the ends of the barrel. The barrel is then raised just enough to clear the ground. The weight is taken, when the next barrel is weighed in the same way. The whole thing is shown in Figs. 4 and 5. It is a great scheme, and I am sure it can be employed to advantage by other bee-keepers.

MARCHANT'S SCHEME FOR SHADING HIVES.

In Fig. 6 we have Mr. Marchant's scheme for shading hives. The ridge piece is made of inch lumber a little longer than the hive, with cheap shingles nailed on to it at right angles to each other, as shown in the illustration. This kind of shade-board is very cheap, and its shape gives a little better circulation of air between the shade-board and the top of the hive than the ordinary arrangement lying flat on the hive.

Fig. 7 shows a four-story ten-frame colony operated for extracted honey. You will notice this stands up on scales for recording the honey-flow. The hive next to it has three stories. Every modern yard nowadays has a scale hive; and as the honey-flow begins to taper off, the bee-keeper will modify his plan accordingly.

In our next issue I hope to show you apiaries up on stilts on that same Appalachicola River, and a few snap shots showing the river itself. I shall also have something to say about the advantage of a river for transporting bees to new pastures.

FIG. 6.—Marchant's shade-board. This provides better ventilation than the ordinary flat shade-board.

FIG. 7.—Marchant's scale hive. There ought to be a hive of this kind in every large yard to keep tab on the honey flow.

CAPPING-MELTERS NOT NEEDED UNTIL THE END OF THE SEASON.

BY E. L. HOFFMAN.

To use a capping-melter during the extracting season adds work at a time when the bee-keeper has more than he can attend to, without any material advantage. Of course, not so many objections can be raised when extracting is done at the home yard altogether; but after arriving at an outyard it takes some time before the melter is hot and ready.

The honey that flows from it near the close of a day's run is not very salable; and nearly all honey taken from a melter is injured in flavor and color. The first gallon or two coming from a melter is of almost perfect quality; but as soon as refuse begins to accumulate in the melter the honey is injured. In melting the cappings from new combs it will be near the close of a day's run before there is much difference in the color of the honey; but the flavor is slightly changed from the first.

At the close of a day's run, there is a great deal of refuse, wax, and poor honey in the melter that must be emptied into some other receptacle to be worked up later for the wax it contains. Emptying the melter and getting it ready again for another run must be done at the close of a hard day's work, when the same time should be used in getting home for as much rest as possible. If this work is left until the next morning, too much time will be lost when the help is on hand to go to work.

The heat generated by a melter is also very uncomfortable for the operator.

I intend to use next season a Townsend uncapping-box to be carried from one yard to another. The cappings are to be taken from the box and left in a receptacle built for that purpose, one at each yard, in which the cappings can drain until the close of the season, after which time they can be collected and hauled to the home yard, to be melted up when time is not worth so much. If you know of a better plan I shall be under obligations to you if you will outline it to me.

Janesville, Minn.

[For some time we have been of the opinion that the solution of the problem lies in draining the cappings in large tanks during the busiest part of the season, and then melting them up later, when they contain a relatively small amount of honey, and, too, when time is less valuable.—ED.]

CHAINS TO KEEP TIERED-UP HIVES FROM BLOWING OVER.

BY A. V. POLLOCK.

I am sending you a photo of a part of my apiary, situated right in town. My wife and I have veils on, and my daughter is sitting on a stump. I have built a frame house having a stone foundation under it which makes possible a good cellar for wintering bees.

The log-chains shown, I put over the tiered-up hives, thinking they would keep them from being blown over in storms. We got 1500 lbs. of honey from 16 colonies last year. We have plenty of willow-herb, red raspberry, basswood, and red, white, and alsike clover.

Mattoon, Wis.

A. V. Pollock's apiary in the town of Hutchins, Wis.

BEES FURNISH MONEY TO BUY 160 ACRES OF LAND.

BY L. E. EVANS.

During the early '80's I purchased a colony of black bees in a shoe-box for six dollars, and at once had the bee-fever, from which I have never recovered. At one time I had as many as 500 colonies in three yards. The three last seasons have been quite poor; but I have managed to get from \$400 to \$800 each season. There certainly is money in bees, as well as pleasure. I have made enough from them to buy 160 acres of land, as good as can be bought in my section.

I have been much interested in the various articles and illustrations describing paper cases for wintering bees on their summer stands. I have experimented considerably along this line myself the past four years, and have succeeded in working out a

method whereby I can winter my colonies one season with another as well as though they were in a cellar. I use insulating paper, and pack each colony by itself in planer shavings.

Fig. 1 shows my apiary with the workshop and honey-house in the background. I make all my hives, sections, shipping-cases, etc. Fig. 3 shows the interior of my shop with the various machines. I have a V-grooving machine for sections, a 24-inch planer, a rip-saw table, and sander.

Onsted, Mich.

♦ ♦ ♦

A HIVE-LIFTING DEVICE.

BY JAMES M'LEAN.

I have nearly forty colonies of bees at present, packed in drygoods-boxes that I bought at the stores, altering them so as to have a slanting roof. I could not get any one to help me put them in the boxes, so I had to invent some way to do the work alone. I made the frame that you see in the picture, and got a pair of small double-tackle blocks from a neighbor; and by moving the machine myself I managed the whole business without any help from any one.

You will notice that I have a hive raised up ready to slip the box under, and then let them down carefully into the box. Of course

FIG. 2.—Honey-house and shop with the apiary in the background.

I stand on the ground to do the work, being perched up there only while the picture was taken. I send this to show how any one can keep bees in a city or village. I have never had any trouble about keeping my bees, as they simply let people alone as long as they keep away from disturbing the hives. The next neighbor east of me has a path through my bee-yard, as it is nearer for them to the postoffice and stores. There are dozens of people traveling this path nearly every day, but we never have any trouble from the bees.

I sell the most of my honey from the house at retail, in 4x5 sections, and can keep it a year without candying in the attic of my house. I am in my 70th year, and have kept bees for about fifteen years.

I failed to pack my bees one winter several years ago, and lost them all but three colonies. I use the Hill device packed with leaves and planer-shavings, and have never lost any, to speak of, when they are packed as described.

Hemlock, Mich.

DAMPENING SECTIONS BY MEANS OF A WET CLOTH.

BY GEO. A. O. BOYUM.

To dampen sections before folding them, take them out of the crate and lay them on a table; then take a white cloth, soak it in water, wring out some of the water, leaving it very damp, and spread it over the sections as shown in the view on next page. Leave

James McLean's apiary and hive-lifting device, Hemlock, Michigan

Apiary of D. W. Bryant, Ethelfelts, Virginia.

the sections covered in this manner until they are sufficiently dampened for folding. When they are ready, they will fold together without making any noise whatever. If they are too dry they will make a creaking noise when being folded. If the sections are very dry it may be necessary to soak the cloth twice or to apply it double. Ordinarily the time required by this method is less than one hour. The moisture as it leaves the cloth settles down into the V grooves, where it is then absorbed into the wood just where it is wanted.

Rushford, Minn., June 19.

BEES IN VIRGINIA.

BY D. W. BRYANT.

I have never seen any thing in GLEANINGS from Virginia. This engraving shows how I arrange my hives with shade-boards

over them. I have kept bees in this place 20 years, and have had Italians of the red-clover strain six years. I find them superior to any others which I have kept.

This picture was taken looking west. My apiary is located on a west slope. I put windbreaks on the north side in winter.

Ethelfelts, Va., Nov. 12.

WHOLESALE REQUEENING.

A Breezy Comment on Current Discussion.

BY H. HARLEY SELWYN.

Isn't Mr. Byer's story, p. 619, Oct. 15, of his wholesale requeening, well told? I can almost see the picture of them in that tent, down on their knees peering into the corners of the hive, eagerly looking for "her," and can almost hear the ever irresistible "There she is!" as one catches sight of the quivering, elongated body of the mother of the hive, always running, squirming, slipping through the denser clusters, or lying motionless in some shaded portion of the hive.

Indeed, it is a fascinating work, and one that causes the dinner or perhaps the breakfast hour to slip by unnoticed

Dampening sections by laying a wet cloth over them for an hour.

until a frantic mother or wife gets up sufficient courage to approach near enough to make her voice heard; for, persuade as you will, she never will believe that the combination of hum and veil can make other noises pass unnoticed.

DOUBLE SUPER WITH EXCLUDER BETWEEN FOR FINDING QUEENS.

But, to touch on the point Mr. Byer has so ably handled, viz., the best process of locating the queen of a populous black colony in order to remove her and replace with one of the Italian strain, it has been the writer's privilege to undertake a like hunt through many hives of blacks; and he, too, has found the plan outlined by Mr. Byer of the greatest assistance. Possibly the following suggestion is even more simple, if any thing, and gives good results: Take two ordinary deep supers; and, after placing a queen-excluder between, fasten well together with shipping-staples. Place this before the hive to be operated on, then remove one frame at a time, and, after a quick glance over each to sight the queen if possible before the bees become badly excited, shake into the empty super. Repeat this performance with each frame, placing them either in an additional super designed for that purpose, or leaning them against the hive. Now ply the smoker on the mass of bees lying on the excluder, and see them vanish through the perforations until none but frantic drones remain; and, unless fortune is against you, there you will find the queen trying with all her might to reach the heart of the underhanging cluster. A moment's glance will decide the question; and if no queen shows up, transfer your attention to the interior of the empty hive, and the chances are you will find her somewhere on the walls or in the corner of the hive. The easiest part of all then (that of pinching her) can be done, although it always seems hard to close down on such very willing servants—at least it has always caused me a feeling of remorse to end so quickly this wonderful organ of reproduction, adored and treasured by her host of followers. Such, however, is the claim of modern bee-keeping; and if we want to hold in check that terrible scourge, foul brood, running rampant through this country, Italian queens, and Italians, too, of only the most vigorous strain, must take the place of the humbler black.

MOVING BEES FIFTEEN MILES ON A FLAT CAR.

This fall I took in charge a yard of about 35 colonies of blacks and transferred them on a flat car a distance of 15 miles from a territory where foul brood is not yet known. It was my first experience in moving bees by rail, and certainly it has shown me that with little difficulty a hundred hives or so could be quickly and safely moved to new pastures for the honey-flow. The hives in question were closed over on top with wire cloth, across the front with a strip of lath. They traveled without a hitch—that is, so far as the bees themselves were concerned;

but the railway agent couldn't get up nerve to weigh each individual hive, so made an estimate, much to the benefit of his nerves, perhaps, but hard on the earnings of said railway; for his tense condition on approaching and handling one to get an idea of its approximate weight was so great that the hive must have felt extremely light, for he figured on only 25 pounds. When in great stress of mind or body it is claimed mankind possess abnormal strength. I rather think he was no exception to the rule. Nor was he the only backward man around that station; for when the freight pulled in, the train hands were quite willing to wait several hours if I would only do the loading; and, in fact, I had to.

These colonies, as I have already mentioned, are the real "black as your hat" quality, and next spring it behoves me to do some queen-hunting extraordinary.

Kirks Ferry, Que., Can.

THE COLORS OF NORTH-AMERICAN FLOWERS.

BY JOHN H. LOVELL.

Beautiful flowers are designed to attract the attention of insects, and they exist only where there are insects to behold them. "In New Zealand," according to Wallace, "where insects are so strikingly deficient in variety, the flora is almost as strikingly deficient in gayly colored blossoms. Of course, there are some exceptions; but, as a whole, green inconspicuous and imperfect flowers prevail to an extent not to be equalled in any other part of the globe, affording a marvelous contrast to the general brilliancy of Australian flowers combined with the variety and abundance of insect life." Very few of the higher insects feeding on nectar and pollen occur in New Zealand. A few years ago only 18 species of butterflies were known, and of bees only 10 species, while at the time of their discovery neither the honey-bee nor bumble-bees were found in these great islands. Flies are here the most important group of flower-visitors.

All orders of insects are much more abundant in both Europe and North America; and in lands where there is an insect fauna, rich both in species and individuals, flowers display an infinite number of brilliant hues and delicate shades which surpass the power of the artist and naturalist to describe. There is a wonderful variety of bicolored, tricolored, and variegated blossoms, often veined and mottled in endless ways. Not only are the prismatic colors—red, orange, yellow, green, blue, and violet displayed by many species with a profusion of intermediate shades, but rarer colors like black, brown, scarlet, crimson, and lurid purple are not unrepresented. Nature has tried her skill as a colorist in the bright translucent hues of corals and sea anemones; in the lights and shades reflected by the scales of the butterflies' wings; and in the brilliant iridescent

hues of the plumage of birds; but nowhere are her inexhaustible resources in chromatics so bountifully exhibited as in the colors of flowers.

See, and scorn all duller
Taste, how heav'n's lover color,
How great Nature clearly joys in red and green:
What sweet thoughts she thinks
Of violets and pinks.
And a thousand flashing hues made solely to be
seen:
See her whitest lillies
Chill the silver showers,
And what red mouth has her rose,
The woman of the flowers!

A flora in which the flowers are all of one color would be at a great disadvantage. The value of color contrasts is evident, for they enable the visitors, more especially the bees, easily to remain constant to a single plant species in collecting pollen and nectar. If they were to visit flowers indiscriminately, much pollen would be wasted and much time and effort lost in locating the nectar. In the Alpine flora of the Tyrol, in the heights above the tree-line, there is no spring and no autumn—only a short summer following a long winter. All the flowers have, therefore, to blossom in this short time. "White and red, yellow and blue, brown and green," says Kerner, "stand in varied combination on a hand's-breadth of space. Hardly has the snow melted, than there appear almost simultaneously the violet bells of the soldanellas and the golden flowers of the cinquefoil, the white crowfoot and androsace, the red silenes and primulas, the blue gentians and the yellow auriculas, the heaven-blue forget-me-not and the yellow violet as well as the saxifrages in every conceivable color." Such a meadow in Alaska, where the summers are equally short, is thus described by Burroughs:

Starred with flowers of every hue,
Gold and purple, white and blue;
Painted cup, anemone,
Jacob's-ladder, fleur-de-lis,
Orchid, harebell, shooting-star,
Crane's-bill, lupine, seen afar:
Primrose, poppy, saxifrage,
Pictured type on Nature's page.

According to a well-known principle of physics, each color appears more brilliant in contrast with other hues than it would if viewed alone. This can be easily shown by a simple experiment, which any one can perform. Cut out two pieces of red paper, each two inches square. Place one of the red squares on a large sheet of green paper and the other red square on a large sheet of red paper. The red square on the green paper will appear so much more brilliant than the red square on the red paper that the observer will have difficulty in believing that they are identical in hue.

Some years ago I began an inquiry as to how many flowers there are of each color in the flora of North America. In northeastern America north of Tennessee and east of the Rocky Mountains there have been described 4020 species of flowering plants, or angiosperms. Partly by direct examination and partly by reference to various systematic works I have tabulated the entire number

according to their predominant colors—a labor which, I need hardly say, extended over several years. I find that in this area there are 1244 green, 956 white, 801 yellow, 260 red, 434 purple, and 325 blue flowers. In every hundred species there are 30.9 green, 23.8 white, 19.9 yellow, 6.4 red, 10.9 purple, and 8 blue.

The green, white, and yellow flowers number 3001, or three-fourths of the entire number; while the red, purple, and blue amount to only 1019. Though there are many exceptions, the first group usually have regular or wheel-shaped or cup-shaped flowers with the nectar easily accessible, and are visited by all flower-loving insects—a miscellaneous company of beetles, flies, butterflies, wasps, and bees. The flowers belonging to the second group are very frequently irregular or one-sided, with the nectar deeply concealed, and are attractive chiefly to long-tongued bees, butterflies, and hoverflies (*Syrphidae*). The tendency of flowers to change from green, white, and yellow to red, purple, and blue, is much stronger than the reverse; but red, purple, and blue flowers usually have the petals white or yellowish at the base and in the bud, and not infrequently the whole corolla reverts to one of these colors.

Have these relations any significance? Undoubtedly they have. They are signals pointing out to us the course our flora has pursued in its evolution. The green, white, and yellow colors are older and more primitive than the red, purple, and blue, and were more common in the primordial flora. The red, purple, and blue flowers are, as a whole, of much more recent origin, and have been developed from green, white, and yellow blossoms. For example, the buterecups are a much older genus than the columbines and larkspurs, and the cinquefoils are more ancient than the pea, bean, or vetch; while, again, the viburnums are older than the honeysuckles. The orchids have certainly developed more recently than the lilies. Occasionally irregular flowers revert to their ancestral stages and produce perfectly regular forms. Individual white flowers may change to red, as in the Sweet William; or to yellow, as in the climbing honeysuckle; or yellow flowers may change to red as in the bush honeysuckle and the lantana.

Let us next inquire how many of these 4020 flowers found in northeastern America are pollinated by the wind and how many by insects. Among wind-pollinated plants are the grasses, sedges, and rushes; many homely weeds like the pigweeds, sorrels, nettles, and ragweeds, as well as many deciduous bushes and trees, as the alders, poplars, elms, oaks, beeches, and birches. After a careful examination of every genus I place the number of wind-pollinated plants (including a few pollinated by water) at about 1046. This number is probably a little too large, for in the case of some western species there are no recorded observations, and they may be self-pollinated. Still it can not be

far from correct, since the grasses and sedges alone in this area include 705 species.

Most wind-pollinated, or anemophilous (wind-loving) flowers are green or dull-colored; but the sorrels are blood-red, and the aments of the birches are golden yellow. Of the 1046 anemophilous species, 1021 are chiefly green, 1 white, 11 yellow, 3 red, 12 purple. Thus there remain in eastern America 2972 species which are pollinated chiefly by insects, or are self-pollinated. Of this number 223 are green, 955 white, 790 yellow, 254 red, 425 purple, and 325 blue. It is evident that bright coloration is correlated with insect-pollination, and dull coloration, or inconspicuousness, with pollination by the wind.

Brilliant flowers usually contrast with green foliage. But in early spring I have seen white and blue hepatics blooming amid sere and brown leaves fallen from the trees the preceding autumn; and contrasting with the dark soil in dense woods I have found the snow-white Indian pipe. In the eternal twilight which prevails in the primeval forests of the equinoctial regions of both the old and the new world there occurs a group of parasitic plants called the *Balanophoraceæ*. There are only about forty species, and the whole plant is colored deep yellow, blood red, or purple. Flowers which rest upon the surface of the water are often white or yellow, as the yellow and white water-lilies. Nocturnal flowers are also generally white or yellow, since purple or blue would be invisible at night.

In the absence of petals the calyx may become bright-colored, as in the clematis, anemone, marsh marigold, and buckwheat; or both calyx and corolla may be colored, as in the columbines, larkspur, and fuchsia. The aments of the willows are rendered very conspicuous in spring by the very numerous yellow and red anthers, while in the meadow-rue the white and blue filaments are broad and petaloid. The small leaves or bracts surrounding the flowers are also frequently highly colored. In the painted cup (*Castilleja*) the bracts are bright scarlet; in *Monarda media* the bracts are purple, and in the bunchberry white, while in the *Proteaceæ* of Australia the upper foliage leaves are blue.

Again, conspicuousness may be secured by massing small flowers in large clusters, or by their production in great profusion. A single bluet is visible at a distance of only a few feet; but when they whiten a whole hillside they form a part of the facies of the landscape. In the town of Wiscasset, Maine, the dandelions when in bloom carpet the whole fields; while in New Jersey large districts are white with daisy blossoms, but, unfortunately, not for the harvest. On the prairies of Nebraska the ground-plum presents in spring a very striking appearance, the plants forming dense masses of reddish-blue flowers. In North Carolina, *Rhododendrum maximum* and *Kalmia latifolia*, or mountain laurel, the two handsomest North-American shrubs, "are seen to cover

tracts of great extent at one season, presenting an unbroken landscape of gorgeous flowers." They adorn the valleys all around, says Asa Gray, in one of his letters, "in immense abundance and profuse blossoming of every hue from deep rose to white." Almost equally conspicuous in various parts of the country are large areas brightly colored with yellow buttercups, goldenrods, sunflowers, orange-hawkweeds, purple thistles, and blue lupines. The blue lupine, or "blue bonnet," is the State flower of Texas, where, says Scholl, "it grows in great profusion over the entire ground, making it look like a solid blue carpet for miles around." But nothing in this world can surpass in beauty or lavish abundance the cloud-like masses of bloom displayed by the great northern apple-orchards.

Compare these brilliant landscapes of color with Wallace's description of the tropics: "I have never seen in the tropics such brilliant masses of color as even England can show in her furze-clad commons, her heathery mountain-sides, her glades of wild hyacinths, her fields of poppies, her meadows of buttercups and orchises—carpets of yellow, purple, azure-blue, and fiery crimson, which the tropics rarely can exhibit. We have smaller masses of color in our hawthorn and crab-trees, our holly and mountain ash, our broom, foxgloves, primroses, and purple vetches, which clothe with gay colors the whole length and breadth of our land. These beauties are all common. They are characteristic of the country and climate; they have not to be sought for, but they gladden the eye at every step. In the regions of the equator, on the other hand, whether it be forest or savanna, a somber green clothes universal nature. You may journey for hours and even for days, and meet with nothing to break the monotony. Flowers are everywhere rare, and any thing at all striking is to be met at only very rare intervals."

Waldoboro, Maine.

FOUL-BROOD LEGISLATION IN CALIFORNIA.

The Necessity of Co-operation between the Northern and Southern Portions of the State.

BY HARRY K. HILL.

On p. 552, Sept. 15, Mr. P. C. Chadwick makes some suggestions about a new foul-brood law for California with the intention of bringing out a discussion. I fully agree with him that the present law is of little force, and that a new law creating a State inspector is desirable. He makes some suggestions about the details of the proposed new law, which, in the main, I agree with; but there are some points upon which I should like to make some remarks; and chief among them is this: He says, "My idea would be to . . . have a State inspec-

tor appointed by the Governor upon the recommendation of the State association." Now, upon this point hangs considerable. The reader may not know that there is a little friction between the bee-keepers of the northern and southern parts of the State, caused, undoubtedly, by more or less misunderstanding. The so-called State association represents the bee-keepers in the southern end of the State, with headquarters at Los Angeles. I am not well posted on their membership, but I think I am well within bounds when I say that they have not a member north of San Francisco, and very few that far north. On the other hand, the northern part of the State is represented by the Northern California Bee-keepers' Association, with headquarters at Elk Grove, near Sacramento. The memberships of the two associations, I understand, are nearly equal; but the northern association has much greater future possibilities. The position taken by the so-called State association in all matters of legislation (and otherwise for that matter) has been particularly galling to the bee-keepers in the northern end of the State. For instance, at the last session of the legislature a bill was presented which would have undoubtedly been passed had it not been for the opposition of our association. On three occasions, I believe, our secretary requested a copy of this bill before it was presented, but never received one. Instead he received a letter advising our association to push the bill, without seeing it, stating that it was to our advantage to do so. Practically the only difference between the bill and the present law was that which would have effectually erased the Northern California association from any further importance in California beedom, making it necessary, if we would have any thing to do with contemporary bee-keeping life, to join them.

I could go on, but have probably said enough to show that conditions are not as they should be. It would be greatly to our credit and mutual benefit to work together. We of this part of the State are not opposed to joining a State association, but it must be a *State association*. Meetings must be held in various parts of the State, not at one particular point; and several other things should be modified which I will not touch on here, although they could doubtless be settled favorably to both sides.

The point I wish to bring out in writing this is that, in a campaign for another foul-brood law, the first points to reckon with are the bee-keepers themselves. The Northern California bee-keepers will undoubtedly object to any law which places the full control in the hands of the State association. It seems to me that the bee-keepers of California can consider nothing more important at their next annual convention than steps to bring about a better understanding between the different parts of the State, as that is certainly of the utmost importance in forcing any legislation.

Willows, Cal., Nov. 30.

BEE NOTES FROM EUROPE.

Buckwheat and Bees.

BY R. LINDE.

On this continent, buckwheat-growing is fast decreasing in spite of its being an excellent feed for pigs. Farmers in heather regions, where sandy soils predominate, say that buckwheat, where fed to pigs, imparts a peculiar sweetness to the bacon; and its hay, though small in quantity, is greatly appreciated. Buckwheat is considered an unreliable crop, although some years it pays well. Being very sensitive, late frosts very often ruin the harvest. This year I have met farmers who had sown buckwheat successively three times, and each time light night frosts killed the young plants.

Generally, buckwheat is sown late in May. The first of July is the date when the white-flowered fields put in an appearance.

As unreliable as buckwheat is to the farmer, so it is to the bee-keeper as a honey-yielder. But when all conditions are favorable, buckwheat yields honey profusely. However, a special market must be sought for buckwheat honey on account of its color and peculiar flavor, which the ordinary honey-consumer does not like.

The old-fashioned skeppist maintains that buckwheat yields nectar during the morning hours only, and that east winds favor the secretion of nectar considerably. Indeed, I have rarely seen bees working in the buckwheat-fields in the afternoon except when the weather in the morning had kept the bees indoors. Whether in that case they gathered much nectar I do not know.

DO BEES STORE MORE WHEN WORKING ON BUCKWHEAT!

In the opinion of the skeppist, bees sting more furiously when working in buckwheat fields than at other times. He further maintains that work in buckwheat fields exhausts stocks rapidly—so much so that they are almost worthless for any later flow. According to him it is, of course, the buckwheat that in one way or other causes the bees to die in such immense numbers. The peasant is always inclined to look for external causes, never suspecting his bees to be at fault. But the real cause of the dwindling of stocks working in buckwheat is very probably different. The skeppist is working with a bee in which the swarming trait is systematically developed. Now, buckwheat comes in bloom just at a time when the old foraging bees that went with the swarms (three and more from one stock) have done their work, and there is not an adequate number of young bees ready to take their place, owing to the fact that brood-rearing stopped for several weeks while swarming was going on.

My own experience in buckwheat-fields does not warrant me to express any opinion as to the assertion that stocks having work-

ed on buckwheat are less valuable for any later flow; but this assertion does not seem to be entirely without some foundation. Some bee-keepers think that it is the strong flavor of the buckwheat honey that makes the bees dull, and renders them more or less indifferent to later-blooming flowers with less pronounced odor.

THE ONE-HOLE FEEDER.

The one-hole-feeder idea, as expounded by the editor, is best taught in England, and for a long time already. In England I became acquainted with a feeder I am now using exclusively. I don't know who the

A feeding-jar having an adjustable opening for the syrup.

inventor is; but it is a splendid feeder, by means of which feeding may be easily adapted to all possible requirements. The illustration explains the construction. One could turn on from one to nine holes; and when the bottle is empty it may be refilled without the bees escaping.

BEE-STINGS AND DARK CLOTHES.

Although I always wear dark clothes when working in the apiary, I experience no inconvenience from them as regards stings, because they are so strongly saturated with the hive odor and with bee products that the color becomes a secondary factor. My black felt hat, however, has many a time served the useful purpose of attracting pugnacious bees away from my unprotected face when an unexpected onslaught happened to render the situation unpleasant for me.

DARK HONEY FOR ANEMIC PEOPLE.

Mr. Editor, you are quite right in your explanatory note to what Dr. Miller gleaned from *Deutsche Bienenzucht*. Basswood honey is not dark, page 614. The fact is, the tongue can not trace the basswood-honey admixture in the dark honey the bees gathered in considerable quantities during July; still another fact is that, in the morning and evening, bees made a great roar in the basswood-trees. About the same time, great quantities of highly aromatic propolis were accumulating in the hives. This propolis remained rather fluid for a considerable time.

It seems odd, but it is a fact, that I sold my dark honey sooner than the light, owing to what I stated in my advertisement in the local paper, viz., that the dark honey, on account of its higher percentage of phosphorus and iron, could be especially recommended for nervous and anæmic persons, scrofulous children, and for all those who have to do much brain work. After this advertisement appeared, the majority of the orders coming in were for dark honey. However, there is one very important difference between my dark-honey customers and my light-honey customers. Rather few repeat orders are coming in from the former in comparison with those from the latter.

HIGH PRICE OF SUGAR.

The editorial, page 611, Oct. 15, regarding expensive sugar for fall feeding, reminds me that, at the time of writing, the price of sugar has not fallen much in spite of the fact that the beet harvest has been very much better than was expected some months ago. Indeed, the beets contain a much higher percentage of sugar than in former years. It is the yield in weight that is unsatisfactory. Bee-keepers in most European countries feel very keenly the indirect tax levied on sugar. In Germany the sugar tax amounts to about \$1.70 per 100 lbs.; in Holland, Austria-Hungary, Italy, etc., this tax is higher still. We are making efforts to get the sugar we need for feeding our bees free of tax. But difficulties arise from the necessity of having such sugar characterized by some admixture that does not harm the bees, but at the same time prevents an illegitimate use of the sugar. Sand, sawdust, peat fiber, etc., have been suggested and tried in some states; also pepper (from capsicum) in conjunction with a coloring matter. These latter means for characterizing sugar have been tried in Holland. The pepper is said not to have any deleterious effect on the bees.

I think \$8.00 for sugar, page 616, Oct. 15, is a rather stiff price. The highest price I have had to pay this autumn was \$7.50, the tax included.

Wendhausen, Wildesheim, Germany.

[We believe it is true that bees sting more when working on buckwheat than when working on a source that is a slower and an all-day yielder like clover. When honey comes in with a rush, as it does from buckwheat, then slacks up and stops, bees become cross. When they are robbing in a wholesale way they become furious when the bee-keeper cuts off suddenly the supply. It has the same effect when nature stops the flow of nectar.

We knew that slow feeding had been exploited more in Europe than in this country. The scheme you show in the feeder is a good one and worthy of adoption in this country. We are convinced that slow feeding has come to stay here. For queen-rearing and brood stimulation it is invaluable. —Ed.]

Heads of Grain from Different Fields

Increase—How to Make it.

1. Which method is preferable in making rapid increase—the Bizzle way of allowing the nuclei to build their queen-cells after division, or the Somerford way of caging the queen and dividing after the colony as a whole has built and sealed sufficient cells? If the latter, what should be done with the queen in the mean time? and would it not be practicable to remove a couple of frames of capped brood and form one nucleus with her at once, and let the cells be built on the remaining frames? This would not deprive one of the services of the queen at all. Further, assuming that in neither case would there be any surplus stores, would there be enough difference in the condition of the nuclei at the end of the season to warrant one purchasing queens for each one when dividing?

2. I have three colonies—one Italian and two hybrid—and wish to increase to six the coming summer. I also want some honey. Now, if I divide my Italian colony (now in an eight-frame hive), and prevent swarming in the two other ones, it will make it, or if I increase by the method outlined by G. C. Chase, p. 655, Nov. 1, which is practically the Alexander way, I shall then have six. Which way, under ordinary circumstances, will be more profitable, taking into account the honey crop and outlook for the following year? Of course, in the former case I would have four Italian queens; in the latter, four hybrids; but as there are far more hybrids and blacks in this locality than Italians it is doubtful if all would be mated purely.

3. Another question: Suppose the Somerford plan is employed, and more than one cell is built on a single frame, and it is desirable to save the surplus queens to requeen black or hybrid colonies. I understand that West protectors can be used; but I have never seen the *modus operandi* described from the placing of the protector to the queen at work in the colony requened, nor even the time limit in removing the virgin from the protector.

4. I have read that combs of honey partly sealed would be taken down into the brood-chamber in the fall. I took the surplus from one colony about Sept. 25; but as there were two or three combs that were not entirely sealed I placed these in a full-depth super along with frames that I had cut the honey from, all but a starter, and put them on a colony to be cleaned up. One week later the hive was opened, and I found that most of the starters had been drawn out and were being filled, and the queen had left empty combs in the brood-chamber and laid about ten or twelve thousand eggs in the super, and went downstairs again. After the brood had all hatched I took the super off about Oct. 25, and there was not half a pound of honey in the brood-nest. I could not use the combs from the super, as they had been spread apart to get fat combs; and no more than six would go into it, so I fed them for winter. Why did the colony act that way? I took this super, cut out all the capped honey, and put the super on my Italian colony, and they will not move a drop of it. They all seem to be loafing around on the combs, and eating when they get hungry. As I let but five combs in it would they not be apt to choose it for a winter nest? What is the answer—Dr. Miller's "kick the hive and run" idea? I have tried this, but the bees seem to chew the comb badly.

5. In July, 1910, I had a black queen mate with a yellow drone, her progeny being 90 per cent banded—from one to three light-yellow bands. This year there has been a constantly increasing reversion toward the blacks, until at present there are not 40 per cent showing any bands whatever. Why? No. You said editorially, about a month ago, that you had never seen any particular feeling shown against newly hatched bees. A few weeks ago I saw a very young bee yanked out of the hive and thrown out in the grass. I picked it up at once but could not find anything wrong with it. It seemed sound in wind and limb, so I opened the hive and tossed the bee down on the frames, where it was instantly grabbed by as many as could reach it, and hustled down and out again. Why?

7. There was a question raised in GLEANINGS as to whether the bee-moth ever lays eggs outside of a hive. It does. I melted up some old comb—stewed it, in fact, for half an hour; then made it into cakes about four inches in diameter, and put a handful of them in a closet in my shop. About ten days af-

ter that, I happened to shift them and found wax-worms, about $\frac{3}{8}$ inch long, very busy making subways in it. As all eggs that might have been in it when the wax was rendered must have been hard-boiled, the wax must have been visited by the moth afterward.

Newfield, N. J., Nov. 9. G. E. NIGHTINGALE.

[1. We would recommend the Somerford plan. The queen that is caged is caged inside the hive, and you will find that the bees will build cells after she is confined, about the same as if she were out of the hive entirely.

2. We would advise you to make the division entirely with the Italian, and run the two hybrid colonies for honey—not because the hybrid colonies are any better for the production of honey, but because it is more desirable to have your increase of the pure stock of Italians. If you use drone-traps on the entrances of the hybrid colonies, and allow the drones of your Italian colony to have free flight, the chances are that the queens will be purely fertilized.

3. The surplus of cells can be put in a West queen-cell protector with a West queen-cage over the protector, so that, when the young queen hatches out, she will be caged therein. As it is usually very difficult to introduce virgin queens that are three, four, five, and six days old, we advise you to introduce as soon as she hatches, or as soon thereafter as possible.

4. When there is a little honey in the upper story of a colony, the bees sometimes take it down and sometimes they will not. A good deal will depend upon conditions. As a general thing, it will take a colony a good while to take the honey down from the upper story into the lower one, and, as a rule, they will not do it. A better way would be to extract these combs if you have an extractor; then put the combs in the hive and let the bees clean them up; then put them back in the honey-house for use next season. If you have no extractor, store the combs containing a little honey, and use them next spring in the brood-nest for spring feeding.

5. Referring to the black queen that mated with a yellow drone, it is hardly probable that her original stock would change after she once met the drone. It would be our guess that the original black queen had been superseded, and that her daughter had taken her place. This thing will happen very often, and a beginner would not notice the change had taken place, especially if the young queen looked very much like her mother, as she often does.

6. There must have been something that the bees discovered that was wrong with that young bee, and yet you failed to see it. From your statement we should conclude that the bee hatched prematurely. Such bees are never tolerated, for the reason they will never be of any use.

7. There has been a great amount of proof introduced of late, showing the bee-moth and the wax-worm will work in old combs or even in cakes of wax outside of the hive. Our old friend Dr. C. C. Miller was certainly wrong on this proposition. The best of us make mistakes.—ED.]

Bees Wintering Without Protection of Any Kind.

One of my neighbors has a colony of bees in a hive that stands on the top of a hill, and is not protected in any way. The brood-chamber is single-walled, and the owner never looks into it, although he gets considerable honey from the super every year.

My brother has a hive of bees that stands on a table, the top of which is not level by any means, for it looks as though it might almost fall over. The hive is single-walled, and the flat cover is badly warped, so there is nothing to keep the cold wind from blowing right in on the bees; but, at the same time, they wintered well last year.

I am wintering some of my colonies by piling cornstalks over the hives on the back and both sides. I put deep supers on the brood-chamber, with a few thicknesses of muslin underneath, confining the bees to the lower story. The corn fodder piled around serves as a protection.

Westfield, Ind.

A. L. BEALS.

[The two cases first mentioned are the exceptions that prove the rule. You are very wise in protecting your bees.—ED.]

In Hunting Queens, Look for the Bee with Short Wings.

I suppose every person has some contrast to look for in searching for a queen; and the more striking the contrast the sooner she is found. I don't know that I have seen in print the contrast that I always look for, and it strikes me the most forcibly in looking for a queen. It is this: Her wings look *very* short. We are looking at their backs, and the wings are the most prominent visible part. When I see the short-winged one I know it is the queen. Of course her wings are not short, but they look so on account of her comparatively long body.

Galena, Kan., Nov. 25.

J. P. BRUMFIELD.

[You have mentioned one of the important distinguishing characteristics that help much in finding a queen. Another characteristic that is often seen on an Italian queen is the color of her abdomen and hind legs. They are yellower than those of a worker. But the greatest help is the behavior of the bees toward her. This last is of great assistance in locating virgins, small and dark.—Ed.]

The Success and Enthusiasm of a Lady who, from a Start of a Nucleus, Increased to 53 Colonies.

You wish to know if I have found your journal interesting and helpful. I have found it very helpful, and much more interesting than I expected. When I bought my first bees I subscribed for your journal as an aid to the bee-work, but did not expect to be very much interested. I have found that bee literature can be very interesting as well as instructive.

You have touched on all the subjects that I desired most to know about, and I have never had to write for information. I started with a nucleus, and now have 53 colonies. I have lost only two in the cellar, and those were short of stores; neither have I lost more than two from spring dwindling. I knew nothing about bees when I began, except what I had learned in the A B C book.

I got all of my information from GLEANINGS, except what I have gained by experience. My bees have always paid their own expenses and something besides. I have all the honey I want to eat, and I count that considerable, for I am fond of it. I have enjoyed A. I. Root's articles on chicken-raising very much.

West Chazy, N. Y., Aug. 15.

L. VA. A. BROWN.

Brood-rearing in Mid-winter.

I should like to know if bees will hatch in the latter part of December in Chicago. I have 100 colonies. While the weather was warm, my bees started to carry in water. I opened the hive and found one comb partly filled with eggs. Do bees need water on account of the brood?

Chicago, Ill., Dec. 15.

R. J. K.

[It is not unusual to find brood in the central combs of a hive in December, especially when there has been as much warm weather as there has been this winter. Whenever there is brood-rearing going on, the bees need water; and that is why, on warm days through the winter, they make such efforts to find it. Very often brood started in winter is lost; for when cold snaps come, the cluster draws together, with the result that the brood, especially that on the outside, if the queen has started quite a little, is abandoned.—Ed.]

Stings Relieve Rheumatism at 80 Years of Age.

Although never very much afflicted with rheumatism I have, for some years, been troubled at times with pain in one arm, and during the last year it affected both arms, but generally only at night. I have some bees which have stung me occasionally; and as my pain has varied I have often thought that the stings which I got might have accounted for it.

Several months ago I had a strong dose of bee-sting cure. For some reason the bees took the notion of giving me a chastening for intruding on their rights, and it seemed as if a regiment had been sent to give a sharp notice, which they did without stint. I think over a dozen discharged their errand faithfully by giving me notice with their probangs; but for about two months I have had no rheumatic pain. I have had no pain at night as before. It has entirely left me.

Detroit, Kan., Nov. 29.

A. M. ENGLE.

Peanut Candy for Bees.

I bought two barrels of peanut candy. The nuts are weevil-eaten a little. I intend to boil and strain this and feed it to the bees this spring. Would it be safe to do it?

Salina, Kan., Nov. 22.

PHARO MILLER.

[In regard to the peanut candy that you have, we should be afraid that it is scorched and darkened in color to give the different flavors. If so, it would be a little risky to feed it to the bees, although if used directly for brood-rearing you might have no bad results. We usually think that the best grade of granulated sugar is the cheapest in the end. If you fed any amount of it in the spring, there would be some danger that some of it would be left over and stored in the sections, which would give the honey a bad taste and practically spoil it for market.—Ed.]

Too Much Pollen in the Hives.

Is there any thing to be done where the bees crowd every thing out of the lower story with pollen? I have just gone through my apiary, and find the hives good, bad, and indifferent in this respect. Some few colonies had only a small amount, having also plenty of brood and honey. Other hives had the lower-story frames almost entirely filled with pollen. These two last classes I have taken account of to see how they come out.

Ceiba Mocha, Cuba, Nov. 5.

R. H. BIGELOW.

[When a hive has an excess of pollen, the only thing to do is to remove the combs containing it and set them one side to be used the following spring. Such combs are often a valuable asset to the bee-keeper. During the winter we would not leave very much pollen in the hive. Give combs of sealed stores, the best you have, then let the bees work out a winter nest, which they will do if you give the stores to them early enough in the season.—Ed.]

Importance of Upward Ventilation for Colonies Wintered on Summer Stands.

The article on p. 664, Nov. 1, "Wintering Bees on Summer Stands," is truly "good stuff." One winter in Kansas I wintered fifty colonies with the loss of only one. This was one of my very best colonies; but it was in a new tight hive, with the oilcloth very carelessly left on under the blanket of chaff packing, so that the bees had absolutely no upward ventilation. I learned the necessity of top ventilation away back in the '40's in glorious New England, when we used the old-fashioned gum or box hive.

THE FIRST SWARM NOT ALWAYS A PRIME SWARM.

I have often known of a first swarm to be led by a virgin queen, and, therefore, to be what is known as an after-swarm.

Carlton, Col.

JAS. H. WING.

Corrugated Paper in the Top and Bottom of the Shipping-case.

That little discussion on p. 712 has stirred me up somewhat. It is one of the rare occasions wherein I differ with Dr. Miller. I should be glad to have a sheet of corrugated paper on both top and bottom of my cases, for the reasons that the editor has named; also because grocers often open the cases on the bottom, making the no-drip arrangement useless. It looks as if the sign "This side up" ought to remedy the matter, but it doesn't. If you will visit the freight depot in your town and take a look at the boxes so marked, you will find that the freight-handlers pay little attention to it.

Newman, Ill., Dec. 4.

C. F. BENDER.

A Good Record for a Beginner.

Last June I got some chufas and planted them about the 10th of July. I harvested them this evening, Nov. 17, and from one hill I got 264 nuts. How is that? I like them well when roasted. California seems to be well suited to them.

How is the following for increase? One colony to start with this year, six combs; increased to four colonies. All combs were built from full sheets of foundation. I have nine extra combs on hand, and took 40 lbs. of extracted honey. I sold one colony for \$5.00.

Sacramento, Cal.

A. D. MUNGER.

Our Homes

A. I. ROOT

NOTES FROM OUR FLORIDA HOME.

It is now Dec. 23; and although we have been here since Nov. 9 I have been so busy (and happy in my many busy tasks) that I have not until this very moment felt like taking time to say a word to the many good friends who are following me—that is, I have not found time to speak especially of this Florida home. Speaking about homes, there are more homes being started just now right here in Bradentown (that is, new houses building) than in any other place I ever visited that I can remember. Most of these homes are started by elderly people; and it is really inspiring, to me at least, to see old men flying around with the alacrity and enthusiasm of boys, helping the surveyor, making the cement blocks that all structures nowadays stand on, and a little later, helping the carpenter and doing a hundred things they perhaps never thought of before, because they are so anxious to get out of the little tent they have been living in thus far all winter until they could get up some kind of little house to live in. So great is the call for rooms that every house, almost, is full to overflowing, one little cottage sometimes sheltering temporarily several families. But this is no great hardship here, for out on the porch is usually a better place to sleep than anywhere indoors.

For the past two months there has hardly been a house-fly visible—at least around our home—and, so far as I am concerned, there has scarcely been a mosquito in evidence, although Mrs. Root declares she has found a few. Just at dusk I have been sometimes annoyed by the almost invisible sand-flies; but a single drop of citronella rubbed on my wrists and neck stops the annoyance at once. Crowded together as we are, there is not only great need but there is an excellent opportunity to show a Christian spirit; and I am glad to tell you we find it almost everywhere. You see most of us are comparative strangers; and it is not only a Christian duty, but good sense prompts us to be courteous and obliging to the new comers in our midst. I wonder if it isn't true that neighborhood quarrels are more common where people have lived a long while in the same place. If so, this is one good reason for going among strangers for a while.

One good brother writes me to know whether, if he has a cottage here in winter, it will be safe to leave it while he goes back north in the summer time. My answer is that our home has been thus left for many summers; and we not only leave all our furniture but eatables that will keep, and we have never lost a nickel's worth that I can discover. Our barn has never been even locked up where our gardening-tools, nails, hammers, and wrenches are kept; but when we get back every thing is just as we left it. Please consider we have colored people in great plenty all around us; but they are, as

a rule, educated and intelligent; but mark this: There isn't a saloon in Manatee Co., and *never has been*. The residents of Florida are, as a rule, all anxious to get people to come into their own neighborhood, even if they stay here only winter times, and on this account every one seems to unite in making it a safe place to leave while you are back home in the North during the summer time. There is something very enticing about the business of starting a temporary little home down in this mild and genial climate where one can work out of doors every day in winter, especially to elderly people who have, perhaps, builded several elaborate homes in the far North. It really does one good to figure out that many of the things we have been accustomed to are not really *needful*, and oftentimes we can actually be happier *without* them. Lots of people are found in barns or even sheds, and in "almost any old place;" and, judging by appearances, they seem to be quite contented and happy.

KEEPING CHICKENS IN FLORIDA; THE TRUTH ABOUT IT.

So many keep asking if they can come here in the winter and make money "keeping chickens" I have thought best to reply at some length. The greatest trouble is in getting *into* the business in the fall and then getting out of it in the spring when you go back north.

One spring, as I have told you, I turned over my flock to a neighbor at a rough guess of 50 cts. each in the spring, and was to take them back in the fall at what they were worth in the market. When I got round again he had been offered 75 cts. each; so, of course, I paid that price. He had what eggs he could get during the summer to pay for their grain; and with the 25 cts. advance in price he came out very well. As I took them back again after the moulting season was over, or mostly over, I did very well. Of course the question came up in regard to loss during the summer. I told him I would stand all the loss where it was no fault of management, and there was very little loss except a Leghorn rooster that cost me \$5.00. He was gone just before I returned, and no one could ever tell what became of him. Well, during the past summer, rump or something like it got among the chickens; and when I got around, there were only about 90 left out of about 140, big and little, turned over to him. Aside from this, everybody (that is, almost everybody) had unusual trouble about getting eggs during the past summer. Neighbors Rood and Abbott say the same thing; and another thing, this time I put in his care almost a hundred chickens of different ages, some of them only two or three weeks old. These, of course, would not be ready to lay, or at least to lay very little down here in Florida, in the six months I was away, and I tell you

it is rather expensive keeping chickens down here for six months without getting any eggs. Of course, there were some roosters to sell when big enough, and he sold about 20 and used some; but the 90 that were returned full grown cost me something like 50 cts. each for their "board and lodging" while I was north, aside from the eggs they laid. He said we would *both* be out of pocket the way it turned out, and I think he was right.

Right in sight out of the window where I am running my typewriter, just across the road from my five acres is another five acres. It was purchased just about a year ago by a gentleman from the North to go into the poultry business. He planned his buildings, including an incubator cellar, had the trees all cleared off, and bought and started his incubator just before I left in the spring. When we got back in November we found on the vacant lot, instead of the poultry-houses, etc., a big white board sign reading as follows:

For sale on easy terms, these lots,
52 by 136 feet.
Apply to _____

When I met him and inquired why the change in program, he replied something as follows:

"Mr. Root, you know as well as I do that there is no money in chickens in this locality. The feed costs ever so much more, and the prices are not as good as in the North; and any extra amount would glut the market."

I said, "How about eggs at 40 cts. a dozen?"

"Oh, yes! you can do very well with eggs; but I planned to raise broilers and roasters that sell in the North for 30 or 40 cts. a pound."

You see he failed to take into account the cost of feeding grain for months before he would be getting any returns. No wonder he decided on going into the real-estate business and selling his five acres cut up into little lots. Various reasons were given by different ones as to why hens didn't lay as usual; and Mr. Abbott declares his hens this year (at least some of them) have moulted *twice*. After I got my hens to laying I took seven dozen eggs into the store, and the clerk asked me how many hens I had. I told him about eighty. He replied:

"Mr. Root, I have a hundred hens, and I haven't had seven dozen eggs in *three months*."

My seven dozen were laid in three days. When he asked if I could tell him what the trouble was I told him I feared one trouble was he was not around with them enough to get acquainted with them. When I first got ours home we got only three or four eggs a day, and one day only two. They just stayed in the house and acted listless, and it was a full month or more before I could get them to come right up to me and be friendly.

GETTING ACQUAINTED WITH THE CHICKENS.

I told the young clerk in the store that the main reason why he had not seven dozen eggs in *three months* from his hundred hens was probably because he did not get acquainted with them. When I first got my ninety hens home I got very few eggs—one day barely two. They would run when I came near them as if they had no other idea in their heads than that I had just come out to chase one of them down for dinner; and, by the way, this is something that should never be done in a well-kept poultry-yard. Even if company does come unexpectedly, if "chicken dinners" is what you "keep hens" for, don't try for eggs at the same time. Well, I commenced at once getting into the good graces of the "biddies." Where we keep grain all the time before them in the suspended metal tubs, as I have explained, it isn't so easy to get them tame; but I tried to bring them some tidbit they liked, every little while, and I carefully avoided coming on to them with a rush so as to frighten them, always talking to them when I came near; and now when I go out mornings to let them out I say, "Hello, chucks!" before I am fairly in sight, and the Buttercup rooster always responds with a peculiar note to reassure any of the timid flighty Leghorn matrons. It took me fully six weeks to get them to running toward me when they saw me coming, and to run about and scratch and sing as a laying hen always does. Eggs are now 40 cts. a dozen; and 9 eggs, or 30 cts., pays for the grain for the whole flock, including the six Runner ducks, so you see all the eggs I get over 9 is profit; or, if it suits you better, *my* pay for the time taken in "getting acquainted."

Yesterday I got 33 hens' eggs and 4 duck eggs; and, by the way, I want to tell you I am getting four eggs from four ducks right along, although my neighbors who have the same ducks they got of me are not getting any such results at all. The old duck that laid 100 eggs a year ago without a break commenced Nov. 23, and bids fair so far (Dec. 27) to do the same thing again. Oh! I must not forget to tell you that one of my young ducks lays an egg as white as any hen's egg; and if she is fed on grain I think few of you would be able to tell them by the taste from hens' eggs. At present my six ducks spend most of their time in the drainage brook or canal, and they come so near getting their feed out of the water and along the margin that I give them only a little corn at night to make them come home, and another corn feed in the morning before they start out on their all-day raid. They are in such a hurry to be let out (so fond are they of the water) that they hardly stop for the corn in the morning. They usually have their four eggs laid by daylight, and welcome me uproariously when I come to raise the trap-door that lets them down into the creek. Once more let me say, it is *getting acquainted* with the ducks that enables me to get eggs when nobody else has any, or only very few.

Well, I have told you so many doleful stories about getting no eggs in summer and fall in Florida that I am glad to give you one on the other side. My old friend and neighbor, Mr. Raub, who did not commence with chickens until past 80, came back here in October; and during November, when nobody else was getting any eggs, he got 700 by actual count in that one month, from 50 laying hens. He and his chickens are not only good friends, but they are well "acquainted."

OUR AUTOMOBILE WHEN WE GOT BACK IN NOVEMBER.

I mentioned, as we were about going north last spring, the trouble with the coil to our machine. Well, after standing idle for six months during the summer time, it started off at almost the first turn of the crank, but, of course, it had the same trouble when starting as when we left in the spring—that is, on account of the defective coil it "limped" a little before it got warmed up. Sears, Roebuck & Co., however (according to agreement), had a new coil here almost on our arrival; and when this was put in place of the old one it worked so perfectly that it is really not only "a thing of beauty" but a wonderful convenience in taking Mrs. Root and myself wherever we want to go. During the spell of hot weather just at the close of the old year, some of our inner tubes in the tires began to play out, it is true; but they were just about a year old; and standing all summer in our hot auto house (which is but poorly ventilated) it was very likely not the best place for them. Neighbor Rood suggests that, when they are not in use, rubber tires should be kept protected from hot *air* and from *light*; and, down here in this hot climate, they should be placed in the coolest place possible. The tubes have been repaired; and as we are now having cooler weather they will likely do us considerable service yet. Even if they do fail soon, the cost of a set of inner tubes will be but a trifle compared with the comfort and convenience of having "a horse always ready to go, fast or slow," and no expense except when he is at work.

FLORIDA FRUITS IN WINTER.

When we arrived the neighbors told us our Japanese persimmons had borne a beautiful crop of fine fruit; but they got so dead ripe they were able to save only one fine specimen for us by tying it on the tree so it would not drop off. We regretted this, and have since purchased a tree that ripens a little later in the winter. After we had been here about a week, Wesley informed us there was a bunch of bananas ready to cut, and this great bunch supplied Mrs. Root and myself with the finest bananas I ever tasted, for nearly two weeks. They made a most pleasing and welcome addition to my "apple supper," and so far I have found them fully as wholesome as the apples. The variety we grow is called Hart's Choice. They are rather smaller than those usually

found in the market, but they are of a peculiar and most delicious flavor. Right close to the door of our auto-house is a large-leaved guava-bush. It is not as tall as I am, and yet it has given us 30 or 40 great fruits as large and as handsome as big beautiful pears, and, to my notion, no pear can equal them. Of course, most people have to get used to them; but a guava shortcake, as Mrs. Root makes them (with a duck egg), is ahead of any strawberry shortcake (for *me*) that can be made. The bush is really a sight with its branches bending almost to the ground, and one more turning yellow (and dropping off if they are not picked) every day. It is fun to see it putting out new blossoms, and green fruit of all sizes coming on all the while. To save inquiries I am glad to tell you that all the fruits and trees I mention here can be had of the Reasoner Bro's, whose nurseries are at Oneca, Fla., only four or five miles from our home. THE EWING BLACKBERRY; DYNAMITE FOR SETTING TREES, ETC.

Friend Ewing sent me four blackberry-plants to be tested here in Florida; and as I am greatly interested in the plan of making a hole for trees or plants with dynamite, I procured at our hardware store a stick with caps and fuse for 25 cts.; and by cutting the stick in four pieces we made four holes, or cavities, one for each plant. The charge was put down about three feet, and it made an egg-shaped cavity as big as a bushel basket, pulverizing the soil and subsoil for a much larger distance around, and making a most ideal condition for any plant or tree to grow. It is also claimed that the gases and chemicals liberated will for a long time keep away cutworms and other worms or insects that might prey on the tender new shoots. I don't as yet know just how true this may be; but my blackberries have all started to grow beautifully. We have since planted a dozen or more trees in the same way, and so far are much pleased with the plan.

MORE ABOUT LARGE FAMILIES.

I was awfully "beat" to see that letter published in the Oct. 15th issue. In regard to the boys helping me in the mines, the laws of Pennsylvania do not allow boys in the mines under 16 years of age, and the school laws require all under 16 to attend the common schools, and I have 7 going to school. Some of them, I am glad to say, have *never missed a day*, nor been tardy once in three and four terms, and have received certificates of merit from the county superintendent of schools. I have one boy, 16 years old last June, who is quite a help in many ways. This is a poor farming locality. Some farmers offer a boy 30 cts. a day for 12 to 14 hours' work or longer. With the high cost of every thing, that would hardly pay for clothes and shoe leather.

You say I suggest that a large family is a hindrance. I assure you, Mr. Root, such a thought never entered my head. At home with your family, big or little, is the best place on earth. Such are my thoughts. Children are never taken care of by others as their parents do it, and it *does* make one do some thinking at times. The happiest men and women in existence (or should be) are they who have good health. I get up at 4 o'clock, and walk a mile to the railroad; travel by rail 15 miles to the mines; enter the mine at half-past 7; leave at 4:10 P.M., travel 15 miles back, and get home at six, through all kinds of weather when able to work, as

this is all the work handy. There are 75 to '00 men who ride on this work train.

You suggest that a family might live on "boiled wheat," which would keep them healthy. Now let us get to conclusions as to what is the best diet for all. We must obtain the facts for this from the accumulated experience of men under various circumstances. Take the Chinese and Hindoo rice-eaters. They are not superior races of people, neither are the flesh-eating Esquimos nor the fish-eating people of Norway and the Pecheras of South America. Either vegetable or animal food a man can live on; but the decision of those in authority is that a mixed diet is best for the average. Take the American—he is always blamed for eating to excess. Where can you find a superior race of people with their mixed diet? Nature's first food is animal food. Milk—what is better? Look at young birds. They are fed wholly on bugs and worms until grown up. Three Springs, Pa. W. S. COHENOUR.

Why, my good friend, you are a rich man already—richer by far than many millionaires, in my estimation. I quite agree with you that the happiest people in the world are those who are obliged to get up at four o'clock, or something like it, and keep busy at something until bedtime. I am usually up at about four o'clock to let the chickens out before they begin to worry, and I keep busy at something until nine or ten o'clock at night. In regard to dieting, if I am correct, Dr. Wiley argues just about as you do; but I still think that I could get along very well and be satisfied and happy with boiled wheat, especially if I had a bowl of milk to go with it, and a little honey or some maple molasses. Notwithstanding, when I feel that I am rather running down, two or three meals with good beefsteak, or, better still, ground meat, nicely broiled, is about the best medicine in the world to get my digestion back into good trim. Perhaps, my good friend, you and I will not live long enough to see what those children you have been talking about will amount to; but with the bringing-up you are giving them, it would not be surprising if one or more should turn out to be millionaires, or something a great deal better for the good of humanity.

INDIAN RUNNER DUCKS, ETC., IN IDAHO.

Dear Mr. Root:—Yesterday, when I got GLEANINGS from the postoffice, a neighbor said to me "I see you get some circulars too." I told him it was GLEANINGS, and added that it was one of the publications that I really read, although I never owned a bee in my life. I am planning to make next spring a start, for it is an awful waste of good honey to let all these alfalfa-fields bloom without a beehive to the square mile.

I read GLEANINGS backward. First I read the poultry department and then your home department—then editorials and Dr. Miller. I happen to know Dr. M., whose smile "never comes off," and I like to read after him.

I read with approval what you had to say of sterilizing certain kinds of criminals. Last winter the legislature of the State of Washington passed a sterilization law, and the other day a man who attacked a girl was condemned to a term in the penitentiary and to sterilization—the first time such a penalty has ever been given a man in this country.

I note in GLEANINGS for November 15, that a correspondent gave up Indian Runners because they laid tinted eggs, and few of them. He says his ducks were fawn and white. Fawn and white Runners nearly always lay more or less tinted eggs; but the penciled variety invariably produces white eggs, and also lay better than the fawn and white; because to get fawn and white, very close and indiscriminate inbreeding has been resorted to. As

to white Indian Runners I have lately learned something of them. I was at Stockton, Cal., a few days ago, judging the poultry show there, and met a lady who told me that she had penciled Indian Runners, and concluded to get some white ones. She paid a high price for some white ducks from a well-advertised strain; but they proved to be such poor layers that she sold her stock and now keeps only the penciled variety.

I am interested in finding proof that Runners need water to swim in in order that they may mate properly and produce fertile eggs. I am inclined to think you are right about it; if so, this complicates the matter for a good many.

I want to congratulate you on your courage in "saying things" about advertisers who overstate matters. Sometimes I think I say too much, and at other times I am somewhat afraid my spine is a little defective.

We are having delightful weather here—cold at night, but bright sunny days and snow-capped mountains in every direction. It is a beautiful country. Every time I go to California, Washington, or Oregon (and I am called into these States often), I come back glad to see Idaho.

Wendell, Idaho, Nov. 22.

MILLER PURVIS

SWEET CLOVER IN SOUTH DAKOTA.

The following from the St. Paul *Dispatch*, dated Pierre, S. D., Sept. 13, is another illustration of the way in which humanity, even good farmers, have been neglecting one of the most valuable legumes God ever gave to mankind, and treating it as a noxious weed.

T. J. Steele, of Sioux City, one of the owners of the Steele and Goudy ranch in western Sully County, feels confident that one of the coming forage-plants of the Northwest is sweet clover. This plant, which has been spreading over the Missouri Valley, making a heavy growth wherever it has secured a foothold, regardless of adverse weather conditions, and showing an ability to thrive on the prairie with but little rainfall, has been looked upon as a pest to be exterminated if possible. But Mr. Steele says it has been proven to him by tests that, if it is handled as is alfalfa, cutting it while tender, and before it becomes woody, it makes one of the best of stock foods; and that it can be grown successfully is made evident by its rank growth wherever it has secured a start on the prairie. It is claimed to be just as good for hogs as for cattle.

Mr. Steele is hunting for a supply of the seed to start a field of it on his Sully County ranch, and to give it tests. It is a fodder for which stock must acquire a taste; but when they once take to it they eat it readily, and the results have been shown to him by men who have tried it.

BOOMING SWEET CLOVER.

There seems to be a boom on in sweet clover. We were among the earliest of farm papers to call attention to the value of this long-despised cousin of alfalfa, and are glad to have our judgment verified. But booms are unsafe things, and a word of caution may well be dropped.

Sweet clover is a money-maker to the farmer who can grow it successfully. But because it is a way-side weed it must not be assumed that it will grow successfully of its own accord. There is a trick to sweet-clover growing which must be learned, or failure will be met with. It has about the same feeding value as alfalfa. It will grow in localities where alfalfa fails. It prepares the way for alfalfa on the same ground. It makes good hay and furnishes good pasture. It renovates the soil. But it is not as good a plant as alfalfa for the purpose for which alfalfa is grown—that is, we don't think it is. —*Farm and Fireside*.

One farmer reports success in killing quack-grass with sweet clover. In view of the fact that the sweet-clover crop, for either pasture, hay, or seed, is almost as valuable as alfalfa, and that it is a great soil-renovator, quack-grass and Canada-thistle victims may well look into the matter. —*Farm and Fireside*, Dec. 9.

Temperance

"HURRAH FOR HOBSON!"

Why can't we have him for President of the United States? I clip the following from *The Union Signal* of Dec. 7:

HON. RICHMOND P. HOBSON INTRODUCES A PROHIBITION AMENDMENT.

On Dec. 4, 1911, Congressman Hobson introduced in the House of Representatives the following joint resolution, which was referred to the Committee on Alcoholic-liquor Traffic, and ordered printed:

Joint Resolution proposing an amendment to the Constitution, prohibiting the sale, manufacture for sale, and importation for sale of beverages containing alcohol.

Whereas, exact scientific research has demonstrated that alcohol is a narcotic poison, destructive and degenerating to the human organism, and that its distribution as a beverage lays a staggering economic burden upon the shoulders of the people, lowers to an appalling degree their average standard of character, thereby undermining the public morals and the foundation of free institutions, inflicts disease and untimely death upon hundreds of thousands of citizens, and blights with degeneracy their children unborn, threatening the future integrity and the very life of the nation: Therefore be it

Resolved by the Senate and House of Representatives of the United States of America in Congress assembled (two-thirds of each House concurring), that the following be proposed as an amendment to the Constitution, which shall be valid to all intents and purposes as part of the Constitution when ratified by the legislatures of three-fourths of the States: 1. The sale, manufacture for sale, and importation for sale of beverages containing alcohol, are for ever prohibited in the United States and in all territory under its jurisdiction.

2. Congress shall have power to enforce, by appropriate legislation, the provisions of this article.

LIQUOR TRAFFIC IN PROHIBITION STATES.

The following was clipped from the *Chicago Advance* (Congregational), and you will notice they clipped it from the *Herald and Presbyterian* (Presbyterian); and if the Baptist brotherhood and the Methodist Church will now indorse it and publish it I think it may do a lot of good. It is just what I have had in mind; but it is told so much better than I could tell it I have copied it entire.

A great deal has been made out of the fact, if fact it is, as stated by the Interstate Commerce Commission, that 20,000,000 gallons of liquor are shipped annually into the nine prohibition States. A great deal *should* be made of it. One is, that every gallon carried into this territory was disposed of contrary to law, by law-breakers and criminals and anarchists, and that the United States furnished tax certificates to many of these anarchists, and gave them a form of protection and respectability in their criminal operations. This ought to be, and *must* be, stopped. No nation claiming a Christian civilization can afford to override or to discourage the moral aspirations and efforts of its people, especially as expressed in the regular form of State laws, as our nation is doing in encouraging anarchist liquor-dealers to break down the prohibition laws made in nine of our States for the protection of the homes and the people.

But another thing being made out of the fact of this importation of liquor into prohibition States is (and a most abject and discreditable thing it is) that prohibition does not prohibit, and, consequently, should be done away with! Why does it *not* prohibit? Because there are some criminals who are breaking the law, and some criminal officers who are not enforcing it, although they are under oath to do so, and are paid for doing so.

Their argument, however, is that, because some law-breakers break the law, they ought to be rewarded for their opposition to the law by having the law repealed.

But it is well to consider the proportions of this feature of the importation of 20,000,000 gallons of liquor into prohibition States. It means that the people of these nine States consume less than one gallon and a quarter per capita, while the per-capita consumption of the people of the other States is 25 gallons a year. Thus even the horrible conditions brought about in the prohibition States by boot-leggers and blind tigers and all other disreputable means for the anarchistic disposal of liquor are only one-twentieth as bad as in the other States, where the saloon is regulated and well ordered, and moral and lovely, and 25 gallons of liquor is consumed on an average by the people every year. The city of Chicago alone, with only 2,000,000 people, consumes 12 times as much liquor as 15,000,000 in the prohibition States consume.

If our good folks in Medina feel inclined, I should like to have extra copies printed for free distribution. They might open the eyes of the good people in Ohio who are making such haste to vote back the saloons because, as they are told, "prohibition does not prohibit."

"WET AND DRY" IN THE RECLAIMED COLORADO DESERT.

Mr. Root:—I have been very much interested in your temperance department, and think perhaps you will be interested in the fight which is now on in Imperial, between the good citizens and the saloon interests. Imperial County (which is the reclaimed Colorado Desert) has been dry since its birth; but a "local option" amendment to our State constitution, passed at the last election, takes the power of prohibition from the counties and gives it to towns; and the brewers of Los Angeles are taking advantage of this to try to force their abominable products upon Imperial Co. The full-page advertisement which I inclose will show you what pitiful arguments they put up in favor of their proposition. The "Progressive League" is composed of the "Pool Hall" and "Blind Pig" element of Imperial. The business men are, I think, without exception, opposed to the saloon. It is too bad that woman suffrage, which has just been passed at a special election, is not yet in force; for if the *women* of Imperial had a vote, the town and county would certainly *remain* dry.

El Centro, Cal., Oct. 24, 1911. D. P. BOTTROFF.

Then follows a full-page advertisement gotten up by the brewers to prove that a careful and well-regulated saloon is better than prohibition—that is, no saloon. Now if these liquor people would just point to a city that is prospering under the reign of the "well-regulated" saloon, it would be a curiosity.

"SLEDGE-HAMMER" BLOWS FOR TEMPERANCE; WHAT A METHODIST PREACHER SAYS.

A few weeks ago in the home of Mr. Wallace Gridley, of Edgewood, Cal. (a very enthusiastic bee-man), I read in your magazine a splendid temperance sermon for which I want to reach a fraternal hand across the country and say "shake! hurrah for you! do it again." Mr. Gridley, who is also a most ardent anti-saloon man, has since given me several copies of the same article in leaflet form, which I shall distribute, hoping and praying they will help us make California dry. It is an awful fight we are in; but such articles as I have mentioned will strike a blow like a veritable *sledge hammer*. God bless you! do it again.

Sisson, Cal., Aug. 1.

NO. 3

Editorial

THERE will be a meeting of apiary inspectors, and others interested, at Amherst, Mass. See special announcement on p. 25.

WE expect to have in our next issue something more to say on the subject of putting lime in the soil to make clover grow on land that has hitherto been considered "clover-sick." Clover in the years gone by has used up the lime in some soils, and it is now time to replace it. It can be done very cheaply.

THE OHIO STATE BEE-KEEPERS' CONVENTION.

THE attention of Ohio bee-keepers is directed to the program of the Ohio State Bee-keepers' convention, to be held at Springfield, O., Feb. 21, on page 25 of this issue. Entomologist Shaw, chief foul-brood inspector, will be present. An effort has been made to get Dr. E. F. Phillips, of the Bureau of Entomology, to come also. This will be an interesting and important meeting. We expect to be present ourselves, and hope that all bee-keepers who can will make an extra effort to attend.

SPECIAL NUMBER ON AUTOMOBILES.

WE are now planning to have our April 1st issue a special number devoted to the interest of the bee-keeper who owns an automobile, or who intends to purchase one. There have been many requests for this; and for the past few months almost every mail has brought us letters of inquiry from prospective purchasers. We are always glad to give information regarding different machines when we can; and in order to call out the experience of others we have planned this special number. We already have several interesting articles on hand, together with some good illustrations; but we are anxious to get a good many more. Let all those who own machines tell why they bought them, whether they are profitable from a business standpoint, etc.

What machine do you own, and why did you get it? Has it proven satisfactory? If you have owned it as long as a year, what has been your expense for repairs?

We are especially anxious to get photographs of various machines in use. We shall expect to pay for all contributions used, especially where photographs are sent that can be reproduced.

SENDING HONEY OR OTHER COMMODITIES BY FREIGHT OR EXPRESS; A FEW FACTS TO REMEMBER.

A SHORT time ago a subscriber wrote us that he had shipped some honey to a commission house, and could get no returns. The case was something like this:

The commission house, it seems, made this bee-keeper an offer for his honey delivered in their city. The bee-keeper did not accept the offer, as he said it was too low. He wrote back that he would have to have more money than they had offered. He received a letter from the commission house, accepting his figures. The honey was shipped; but on arrival it was found to be badly broken down. The commission house would make no returns, and the bee-keeper finally appealed to us. We replied by saying that if he, the bee-keeper, had accepted the price offered by the commission house, f. o. b. city of the commission house, he would be compelled to accept whatever terms of payment the commission house could make, after making reasonable allowance for breakage; that his only recourse would be to put in a claim against the railroad company for the difference between what he received and what he would have gotten if the shipment had not been damaged; but as the commission house had accepted the honey f. o. b. station of the bee-keeper, it was up to them to make full returns on the basis agreed upon, and then enter claim for loss against the railroad company.

The moral of this whole thing is, that it is to the interest of the bee-keeper to have the honey delivered into the hands of the railroad company of *his own town, and no further*. It is equally obvious that it is to the interest of the buyer to secure, if he can, delivery of honey to his city.

There is one other point to be considered, however, and that is this: If the bee-keeper puts up his honey in a careless and improper manner, neither the buyer nor the rail-

road company could be compelled to pay the full loss, if they paid any thing. The loss would then fall on the producer. It is, therefore, important that the bee-keeper put up his honey in the most approved style, using modern well-made shipping-cases; and if he can prove that the honey was delivered at the railroad station in good order, any loss or breakage in transit can then be recovered from the railroad company by either the consignee or shipper.

Another case arose some little time ago. A bee-keeper shipped his household goods from a southern city to a northern. He prepaid the freight to the agent at the starting-point, which was \$12.00. This charge was based on an estimated weight of the goods. When the goods reached the northern city the agent at destination demanded \$3.85 more, which was paid. A short time later the railroad company demanded \$5.50 more. The bee-keeper demurred, and wrote to us, asking for his rights in the matter, saying that the railroad company threatened that, if he did not pay, he would be held liable to a fine of \$3000 and a term in the penitentiary. He was willing to pay what was right, but he did not propose to be imposed on.

We replied, saying he made a mistake in not knowing the exact weight of the goods when they were shipped; that the railroad agent at the starting-point had no business to "estimate" the weight. But this thing is done very often; but if any trouble arises it always falls on the shipper; and in this case it seems that, when the goods arrived at destination, the estimated weight was found to be too low, and the agent at that point figured up the difference and demanded \$3.85. Later on, the railroad company discovered that the *rate* made in the first place was wrong, and this necessitated additional payment.

We do not wonder that our correspondent thought he was being imposed on; but the facts are, the railroad company had the advantage. If the poor shipper does not pay the full amount required by the rate and the weight of the goods, the Interstate Commerce Commission when appealed to can compel him to do so or take the consequences, and the consequences are something serious. We do not know whether the railroads of the country have secured a set of laws in their favor or not; but clearly they have the advantage in such cases over the shipper. On the other hand, there is no rule but what will work *both* ways. If the shipper can prove that the weights made by the railroad company were too high, or that the rate charged was in excess of the proper amount, and appeals to the Interstate Commerce Commission, that body will require the carrier to refund the difference.

Moral 2.—Carefully weigh your goods before you ship them; then when the railroad agent weighs them again, make sure that his weight corresponds with yours. If there is a discrepancy, ascertain where the mistake is before the goods are shipped. Second, ascertain what the rate is on the class

of goods shipped. Make the agent show you the schedule. Keep all of your records; and then if there is any trouble, and the shipment is a large one, present the facts to an attorney.

DOUBLE-WALLED PACKED HIVES V. SINGLE-WALLED WITH A PAPER COVER.

THE readers will doubtless be interested in the symposium on this general question in this issue, on pages 73, 74, 75, 76, and 77. It is our opinion that this question of packing, absorbents, and size of entrances, is more dependent on locality than we had, perhaps, supposed. Mr. A. C. Miller, an excellent authority, seems to prefer the single-walled hive with black paper for a winter wrapping, or, rather, perhaps we should say, he concludes that there is no advantage in having the walls made thicker. He prefers large entrances on the *sides* of the hive and sealed covers. While he says nothing about sealed covers, he makes no provision for the moisture to escape upward, but, rather, to pass out through an entrance of ample dimensions. We do not question the accuracy of his judgment for his locality; but from exhaustive tests we made some years ago we are thoroughly convinced that bees in single-walled hives in this locality, even with paper covers, either died outright or were so weak in the spring as to be good for nothing for honey-production the following season. We did not at the time take any readings of the inside and outside of such hives; but we see no reason to question Mr. Miller's statement, that the difference in temperature between the outside and inside would be very slight with so large an entrance, and with walls so thin.

It is probably true that a contracted entrance, whether in a single-walled or double-walled hive, would not be advisable in his locality—that is, providing no upward ventilation were allowed. But conditions in other localities are so different that we feel very certain that the plan he recommends would not work in most of the colder climates; and Mr. Holtermann and Mr. Byer seem to be equally certain that they must have more packing for their localities. Mr. J. E. Crane, who is visiting us to-day, Jan. 20, expresses himself as decidedly favoring the views taken by Mr. Byer and Mr. Holtermann, and Mr. Crane is one of our most successful bee-keepers in Vermont.

Perhaps an illustration would help to make it plainer why we favor a double-walled packed hive rather than a single-walled hive. During the past season we built a small garage for storing an automobile. The structure was made of $\frac{7}{8}$ lumber planed on both sides, and painted on the outside. This made a single-walled building, for we did not think it necessary to go to the expense of making double walls, because the building could be easily heated by exhaust steam from the factory. Now, it happened that a radiator in one of the living-rooms in our house was altogether too large for the size of the room. The temperature would go up to

80 and even 90, even when the weather was very cold outside. This room had two outside exposures and two good-sized windows; but the house was sheeted with inch pine lumber on the outside, and over this was nailed tar-felt paper. Over the whole was nailed ordinary siding. The inside walls were lathed and plastered in the usual way. It was very easy to warm this room in the house with that radiator.

Now, it happened that the inside cubic contents of the garage were about the same as those of the room. We concluded that, if that radiator was too much of a good thing for a double-walled room, it would be just about right for a single-walled room of four sides and a roof of exposure. What was our amazement when we found that, even in moderate weather, this big radiator would not make the garage warm enough so that the motor would start readily. When the temperature was down to zero outside, the temperature inside of the building was far below freezing. When that radiator was in the house, in a double-walled room, it would run the temperature up to 80 while the mercury outside was at zero with a high wind. We were at a loss to understand why this garage should be so cold with a radiator going all the time, night and day. On placing the hand on the siding we saw the reason at once. The boards were as cold as a block of ice. Indeed, it became very apparent to us that the outside cold penetrated those $\frac{3}{4}$ boards to a much greater degree than we ever supposed. So little did they keep out the cold that a pail of water would freeze solid within two feet of the radiator.

Now, then, to the application. A colony of bees, even though it be contracted down to a comparatively small ball, is a miniature radiator, i. e., a source of heat. The closer a thermometer is placed to this ball of bees, the higher the temperature will go, providing the entrance is not too large. Now, if this little ball of bees is a radiator, and if those bees have to keep up their body heat by consuming honey, the colder the atmosphere *around* the cluster, the more food will be required. Overfeeding is quite sure to cause dysentery before spring. If the hive is single-walled, an immense amount of cold will penetrate those walls, making the problem of the bees to keep the cluster warm much greater. The thicker the walls, the larger the cluster, and the more it can expand over the food. It would seem that, for most localities, a moderate entrance with a double-walled packed hive will give better results in wintering than a single-walled hive or one protected by any kind of single thickness of paper. The question of the size of entrances and of upward ventilation or sealed covers will depend largely on locality. We are beginning to favor a flat board laid on top of the hive, not sealed down. This permits a moderate entrance and a slight amount of upward ventilation, but not enough to make the packing above damp.

The thermometer readings inside and out-

side of the hive by Mr. Byer and ourselves on pages 77 and 78 would seem to favor double-walled packed hives. The actual difference is anywhere from 20 to 40 degrees where the outside temperature has not taken a sudden change. A zero atmosphere or a few degrees above must be bad for a cluster, especially if it continues for days.

THE CENSUS OF 1910; THE MARKED DECREASE IN THE NUMBER OF BEES ON FARMS, AND WHY.

BEE-KEEPERS have been waiting with interest for the returns on the bee-keeping industry from the Census of 1910. Part of the data is now available and is presented herewith, together with similar data from the Census of 1900. That there has been a decrease in the number of farmer bee-keepers, there can be no question. Whether the tables showing this decrease by States are accurate we can not say; but decrease there surely has been. This is probably due to two causes; viz., 1. To a reduction in the amount of clover grown, either because intensive agriculture has crowded it out, or because soil that once grew clover luxuriantly has become "clover-sick"—that is, too acid. Clover is the main dependence for honey in most of the States east of the Mississippi and north of the Ohio. It is a notable fact that clover doesn't yield as it did in the olden days before the lime had been exhausted from the soil. When "bees don't pay" on the farm, they die off because the farmers won't feed them. We shall have more to say about this at a later time. 2. The other cause for reduction in the number of farmer bee-keepers is clearly traceable to bee disease that has made such rapid spread. The obvious remedy is to work for more extensive bee-inspection work and, besides, preach the doctrine of putting lime in the soil. That can be done cheaply, and make clover grow as before. While lime can have no effect on bee diseases it will make clover grow as it did in old days.

Attention should be called to the fact that these data are for bees on farms only, and that bees in towns and cities are not included. The official designation of a "farm" actually includes many apiaries in towns; but, as is well recognized, most of the large town apiaries have not been included in the enumeration. At one State bee-keepers' convention last winter it was found that approximately three-fourths of the bees there represented had not been included in the count. It is obviously not at all fair to the bee-keeping industry to count only the bees on farms when many of our largest bee-keepers are not on farms, but are in small towns or even in our larger cities. It is understood that no enumeration was made in the Census of 1910 of bees in towns and cities, and it is hoped that, before another census is taken, the authorities in the Census Bureau will learn that bee-keeping is not confined solely to farms.

The data presented shows a decrease of

116,408 in the number of farms reporting bees, and of 795,719 in the number of colonies reported. The valuations put on colonies of bees by many bee-keepers are of little significance; but it is interesting to note that these valuations show an increase of \$193,139. The only States showing any increase in bee-keepers, worthy of serious consideration, are Minnesota, Oklahoma, South Dakota, Washington, Montana, Wyoming, and North Dakota—all western States. The greatest reported loss is in Utah, where a decrease of 49.5 per cent is shown in the number of farms reporting bees. It is worthy of consideration that the loss in number of farms reporting bees is usually greater than in the number of colonies, indicating that those now in the business are keeping more bees.

Bee-keepers should not take any of these figures too seriously, for they certainly are not an accurate representation of the industry. Apiculture was never in so good condition as it is now. As an indication of this, it may be stated that the demand for

supplies during the last decade exceeds that of any previous period, and the markets for honey are continually improving. Honey production is fast becoming the business of the specialist, and, as a result, honey is being marketed in better shape and in larger quantities.

While it is true that these figures are not to be taken as seriously as the Census Bureau might wish them to be, yet it is a good thing for us to realize that there has been a falling-off in one part of the industry. If, as suggested, the brood diseases are a factor in this decrease, it emphasizes the necessity for spreading information on this subject so that those bee-keepers who have it in them to be good bee-keepers may be informed on this subject. Nothing will save a careless bee-keeper when disease reaches him.

In spite of these figures, there is no reason to doubt that there will be more colonies of bees in the United States in 1912 than ever before, and that the industry is on the increase.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

A FIGHT between queens is mentioned as an attraction at a bee convention in *L'Apiculteur*, p. 466.

DR. WEYGANDT says the Caucasian is the original race of bees from which all others are derived.—*Bienen-Vater*, 334.

THE WARDEN of the Illinois penitentiary at Joliet, Ill., says that 90 per cent of the men are there on account of liquor, and that out of 158 life men all but four or five committed the crimes for which they are in prison for life while under the influence of liquor.

PLEASE ALLOW, Mr. Editor, an addendum to the good advice given p. 26. When the colony attacked by robbers is carried into the cellar, set in its place an empty hive of similar appearance. If you don't, the robbers will pitch into the next hive. Besides, if you leave the place vacant, when you put the hive back again the robbers will notice the change, and will say, "There's our prey back again." [Good correction! Thanks.—ED.]

DER DEUTSCHE IMKERBUND (German Bee-keepers' Confederation) now numbers 82,547 members.—*Bienenzucht*, p. 183. We have a few things yet to learn from the Germans. [It would be interesting to know what is the basis of their organization. Is it fostered by the state? or do the members pay annual dues and receive something in return which justifies them in renewing year after year?—ED.]

YOU ASK what's the difference between a comb in a brood-frame and a comb in a section. None if the comb is the same. But in a section it is not expected brood has been reared, and it is expected in the brood-frame; and my experience is that moths greatly prefer the old black comb. You ask why the moth should not lay eggs in sections if she lays in combs that have been fumigated or frozen. I don't know. May be the cocoons make a difference.

SIX COLONIES of bees, well packed, were successfully shipped in winter, in Hungary, 335 miles by rail and 2½ by wagon, during the last of their journey enduring a temperature of 20 degrees below zero, Fahrenheit.—*Leipz. Bztg.*, 154. [We believe it to be entirely possible. Trouble, if any, probably would not manifest itself immediately but later on. If the bees were set down on stands outdoors we should expect the disturbance would cause a heavy mortality later on. If, on the other hand, they went into a cellar where the conditions were ideal, no bad results would probably follow.—ED.]

DR. HERING, *Bienenzucht*, XI., quotes GLEANINGS as recommending the feeding of thin syrup in the open to prevent robbing at late extracting, and says, "We doubt whether this will have any result. The

strong aroma of the extracted honey and the odor of the open colonies will, of course, attract the robbers more strongly than the thin syrup." But, doctor, you have to believe what you see, don't you? [GLEANINGS never advocated feeding sweetened water during extracting seasons to prevent robbing. We have always recommended, or supposed we did, honey thinned down with water. While probably not very much sugar-sweetened water would get into the extracting-combs again, we think it advisable to avoid any appearance of evil by feeding honey thinned down to the consistency of nectar.—ED.]

J. L. BYER says, p. 5, that for his latitude outdoor wintering is best. I'm in lower latitude, and cellaring seems best here. But that doesn't say Bro. Byer is wrong. I suspect that he doesn't have the hard winds, *long continued*, that we have here. [Is it not possible, doctor, that, if you were to try outdoor wintering again, you might discover that it is more to your advantage to use it than the indoor plan? Mr. R. F. Holtermann says he would not go back to the old way under any circumstances. When we suggested to him that bees wintered outdoors consume more stores he said, "Yes, but they are correspondingly stronger in the spring. As a rule, indoor-wintered colonies do not raise very much brood; while those outdoors will often begin brood-rearing on a small scale in February and March—two months before they would do very much at it in the cellar.—ED.]

Sweet Clover as a Renovator of Poor Soil.

Mr. Frank Coverdale, in his articles on seeding sweet clover, lays emphasis on the need of having the soil fertile. Now, the farmer who has these conditions is all but ready to sow alfalfa, and is much more likely to go on and seed to that plant rather than to something about which he has heard such conflicting reports as with sweet clover.

The great opening for sweet clover, provided it can be made to do the work, is as a renovator of impoverished soils. That in the wild state it grows and flourishes upon the poorest soils is a matter of every-day notice. That there should be any extensive failure to grow it on poor soils would seem to be due to but one cause. That sweet clover and alfalfa have the same nitrifying bacteria is frequently mentioned, and the need of soil inoculation for the latter often urged. That legumes are chiefly benefited by such bacteria on poor soils is also known.

The means by which its seed is transported in the wild state, on wagon-wheels, by streams, and from railroad gravel-pits, are well calculated to secure this inoculation, and doubtless explain its cosmopolitan nature under such conditions. On the contrary, seed harvested from standing plants has little chance of carrying the bacteria; and unless they are supplied they will be liable to failure on soils in which they are necessary to a good growth. Then why not inoculate for sweet clover? If by working in about 200 lbs. per acre of earth from a sweet-clover patch, the soil-enriching powers of this plant can be secured, it certainly ought to pay to take the trouble, and no harm done the bee business either.

McConnellsville, O., Dec. 11.

H. D. TENNENT.

NOTES FROM CANADA

J. L. BYER, Mt. Joy, Ont.

Thanks, friend Crane, for that word of good cheer, page 745, Dec. 15. May your prophecy concerning next year be correct. However, while I am not fretting about what we can not help, nevertheless my faith is not very strong for a good crop of honey in 1912. I hope I may be "disappointed."

Much evidence seems to be accumulating as to the efficacy of carbolic acid used in different ways in the handling of bees under various circumstances. The use of this drug for this purpose has been quite common in the British Isles for some time; but so far as I know it has been used but little in Canada. I am looking forward to trying it some time next summer, as I am convinced that it must be a good thing for certain manipulations of the hive.

A correspondent of the *British Bee Journal* asks for the best method of extracting wax from brood-combs, and expresses the idea that the screw presses advocated by many are too expensive to justify him getting one. The editor of that journal advises him to get a "solar," and says that is the best and cheapest way of extracting wax, adding that they will soon repay their cost. Can the editor really mean that a solar is the best arrangement for getting wax out of brood-combs? Why, here in Canada we have much hotter days than they do in England, and the solar that will not leave anywhere from 25 to 50 per cent of the wax in old brood-combs is yet to come under my notice. Last August I happened to be in a large apiary conducted by an old gentleman, and he asked me if we ever tried burning the stuff from the solar wax-press after the wax was *all out*. He said that his women folks liked it when they wanted a particularly hot fire; and when I saw them putting some of this stuff in the stove I didn't wonder it made a good fire. Oh how I ached to get hold of a few tons of that kind of *fuel*! It would not have gone into a stove. A solar is all right for cappings or bits of comb, etc.; but in my opinion it is worse than useless for brood-combs. More than that, since disease is getting so evenly distributed over the country, I now regard that kind of wax-extractor as being a very dangerous arrangement in the hands of many bee-keepers, and for my part I would gladly see solar wax-extractors become a thing of the past.

Bees wintered outdoors had a good flight in most localities in December. Up to date (Jan. 1) we have not had nearly as severe weather as at this season a year ago; in fact, the thermometer has not yet reached the zero-mark, although just now we are threatened with a cold wave. There was much rain and mud in December, and a farmer

was telling me that, with the freezing and thawing, some of his red clover was heaving a bit—an unusual circumstance for this time of the year. However, with colder weather now, there will be no more danger along that line for a while. As for the alskike heaving, there is no need for worry, as there is very little here to heave. Although the weather has been mild, from all reports received so far the bees indoors appear to be wintering well. A few days ago a friend living near where our east apiary is wintering inside of three caves built right on top of limestone rock, wrote me that he had just been in the repositories, and that all were dry and nice, and the bees so quiet that one would not know they were there.

The principle on which these "caves" are constructed appears to me to be sound, and they might be all right in localities where it is not advisable to go deep into the ground. They have given perfect satisfaction for a number of years. Sometime I will illustrate them for the benefit of the readers of GLEANINGS. This winter 280 colonies are in them, and in past seasons as many as 400 have been wintered with good results.

A. C. Miller is a close observer, but I can not agree with his conclusions as to how different methods of clipping the wings of queens will affect their chances for being superseded. For a number of years I have clipped the queens while they were on the combs, and I *try* to get more than half of all the wings off. I can not see a bit of difference so far as their usefulness is concerned, compared with those that have only the tips of one side cut off, or any other particular style of wing-dressing that may be in vogue. Two years ago I reported having a queen that lived to be seven years old—no doubt about the matter at all, as I had proof of my assertion. Well, the man this queen was purchased from had the habit of taking all of the wings off pretty close, and in this particular case he had outdone himself and clipped all her wings off close. She looked very strange, and was always easily seen, even though she was a dark Carniolan. As to her qualities, I need not say much about them, considering that she was alive till seven years of age. She was very strong every year till the fifth, but only moderately so the last two years. Combs full of brood sealed all over—as if all eggs had been laid in a day in that comb—did not look as if she were hampered much by having no wings. But then, who knows but that she might have been better and lived till more than seven years if she had been properly clipped instead of being marked as she was? However, I should like to have a hundred queens like her so far as her good points were concerned, and wouldn't object if they had their wings off either, as I do not think it would hurt them a bit.

Bee-keeping Among the Rockies

WESLEY FOSTER, Boulder, Colo.

Just take this pointer, all you contributors to GLEANINGS, including myself: Tell your little story as simply and naturally as does Miss Lucille Johnson, page 754, Dec. 15.

ABUNDANT SNOWS.

We are having an abundance of snow and cold weather in Colorado at the present time. The snowfall on the ranges has been heavier than for several years, and an abundant supply of irrigation water is practically assured.

AUTOS FOR BEE-KEEPERS.

The automobile is about the liveliest subject among the bee-keepers at the present time. It seemed that, before and after every session of our Colorado State convention, the members would be discussing autos and their use for out-apiary work. Autos that will last for several years for bee-keepers' use are now so moderate in price that it is a question whether a progressive bee-keeper can afford to be without one. They have come to stay, and those most loud in their praise are those who are using them. Several machines will probably be purchased as the result of the informal experiences given at the convention. The machines most generally in use in Colorado are light runabouts or auto wagons, the latter similar to the International auto wagon which will carry one thousand pounds. Motor cycles are quite popular with some bee-keepers for use in getting to their out-apiaries. [See editorial.—Ed.]

Mr. F. Rauchfuss, manager of the Colorado Honey-producers' Association, recently told me a few things about the honey situation in the West, which would do every Western bee-keeper good to know. Extracted honey, over and above that which can be sold in the local markets, has to be sold in the East in competition with Southern and far Western honey. Comb-honey markets have been developed which demand Western honey, and pay a good figure. The Pacific coast has a more favorable freight rate on the shipment of extracted honey than has Colorado and the intermountain region. Comb honey, the past season, brought \$2.75 to \$3.25, while the very best extracted water-white alfalfa honey sells slowly at not over 7 cents in large quantities. Under present conditions there is no doubt whatever that comb-honey production pays far better than extracted honey. In making these statements I am speaking of Colorado and the intermountain regions only. The average bee-keeper finds that he can sell a few cans of honey around home for 10 or 15 cts. per pound, and straightway figures that he can make more money with extracted at this price

than with comb honey at 11½ to 12½ cts., when he has to buy sections, foundation, shipping-cases, etc., and so he goes and changes from comb to extracted honey, soon finding that he can not market his increased product around home, and has to put his nice alfalfa stock on the market in competition with honeys of cracker-factory grade. Extracted-honey producers in Colorado, within the last few years, have had to accept 6 cts. for white alfalfa honey to be used by cracker-factories because they could not find a market for this table honey. At the present time there are five or six carloads of extracted honey in Colorado, and probably not one carload of comb could be found if the whole State were carefully gone over.

BEE-KEEPING EXTENSION.

There are several problems before Western bee-keepers that may not affect those in the East. Here there are many specialists who do not look with favor on bee-inspection. They hope that foul brood will soon clean out the little fellow and leave the field to himself. Is he right? He figures that he can keep foul brood from gaining a foothold in his own apiaries while it is destroying the bees of his less watchful neighbors, and he does not want the inspector to come around and show them how to get rid of the disease. What is the course to pursue for the best interests of the bee-keeping industry as a whole?

A few have spoken to me that were doubtful of the good of having bee-keeping represented on the farmers'-institute courses. They take the stand that it encourages many to take up bee-keeping only to become discouraged later on and lose money by the operation. Then it tends to overstock the field, they claim.

What is the best course to pursue? Stop all bee-inspection and bee-keeping extension, and let the industry go as it has, or try to educate the beginners in the best methods? This subject arouses bitter argument in some places in Colorado and the West.

The whole tendency of the times is toward specialization, and the specialist feels that the ignorant amateur or careless box-hive bee-keeper is a thorn in the flesh. He does not believe such men can be taught; he thinks the only way is for him to become discouraged and sell out to the specialist. There are fewer bee-keepers in Colorado than ten years ago, but more good ones, and there are a goodly number of first-class small bee-keepers. I know some farmers who are really good bee-keepers, and who welcome suggestions and help through farmers' institutes and farm papers, bee-inspection, etc. Let's hear from others on this question.

Conversations with Doolittle

At Borodino, New York

ADVERTISING AS PRODUCERS.

I have been reading the *Rural New-Yorker* for the past year, and I notice that many of the producers of apples, potatoes, beans, etc., put inside the packages a slip of paper, or something of the kind, telling what they received as producers, and requesting the consumer to let them know what he paid for the same. From data received in this way the *Rural* figures that the producer gets only about 35 cents of the consumer's dollar. This seems quite unfair to the producer, and gives a clue to the reason why we bee-keepers receive so small a price for our honey when compared with most of the things we have to buy. Now, while I would not advocate the same plan, I have been wondering why it would not be a good plan to put our names, as producers, on every crate of comb honey we send out, if not on every section, using a pretty stamp therefor. Then by sending out only a gilt-edged article the consumer would soon know of whom he could buy the best honey, and in this way the progressive bee-keeper might build up a most profitable trade, while those who work only in a slipshod way could be shut out from hurting us by selling their product for less than good honey is worth, as is so often done by the careless and indifferent.

This question carries me back more than a quarter of a century, when I was producing much more comb honey than our home market would consume, which obliged me to send quite a share of my crop abroad. I sent some to different counties in this State, and in States adjoining, and reasoned that no buyer should object to the producer's name and address on the packages of honey which he produced, and even went so far as to procure a rubber stamp, and put my name on every section. This was very little trouble if done just before the cover to the crate was nailed on, as the sections were all in rows, so the stamp could be pressed on each almost as soon as it takes to tell it. As I "wielded" this stamp I said to myself, "If the producer or manufacturer of an article has not the right to have his name on it, I don't know who has. How is a honey-producer going to advertise his business and work up a trade for his product unless he places his name on every section of honey he considers a No. 1? It has taken me over fifteen years to learn how to produce a real fancy article of comb honey, and I should be foolish to give this away to some one who happened to buy my honey expecting to sell it again. Those purchasing to sell again have a right to place their name on the *package* as the seller of it, but in no way should they be allowed to mark it or the sections so as to advertise themselves as the producer."

About this time I took a sample of my section honey to a buyer in Syracuse, N. Y., taking a section from each of the different grades which was produced that season, expecting to put my stamp on only that which I considered a fancy article, as I did not consider it good policy to stamp the inferior grades. The buyer looked the samples over, got my prices for each grade, then about the quantity I had, made a few figures, and offered me about \$25.00 more than I expected to get for the whole crop. Of course I sold it to him. I then asked him

how he wanted it put up. He said, "Put as near as you can the proper proportion of all grades in each crate." I objected, and then told him how I had been in the habit of putting my stamp on each section of fancy and No. 1 honey, putting that in crates by itself, while the off grades went without the stamp. He said that he had bought the honey, paid me a good figure for it, and it should be his right to dispose of it as he saw fit, to which I had to agree or be guilty of not living up to my part of the contract. We then talked the matter over, and he agreed that, where I did my own selling to the consumer, I was right in wishing my name on every package, as that would hold me and the consumers together. But with him as a buyer the case was different. He was building up a trade there in Syracuse and in other cities, reaching out into other States, therefore he wished to have his name on every package, and not that of the producer. He then went on and told how he was spending time and money and energy and thought in building up a market for honey in all these cities, and considered that it was only reasonable that he should reap a reward for so doing. He did not advertise that he was the producer of the honey he sold, but tried to impress upon his customers the idea that he was an expert judge of honey, and took great pains to secure that which was of excellent quality. He took great pains to live up to his professions, and always furnished an excellent article, and thus led his customers to believe that, when they bought one, five, ten, or twenty-five crates of honey of him, they could rest assured that it had *his* guarantee that it was all right. He said that, if he should send out honey having upon the sections the names of the different producers of whom he purchased, he would never succeed in building up a demand for the honey he bought, for one day he might be selling honey stamped Doolittle, and the next day that stamped Jones, and so on to the end of the list of producers from whom he bought. When we were through with this talk I saw that there were two sides to this as well as to many other questions, and that, if I produced more honey than I could sell at retail, or direct to the consumer, the buyer of this overplus was entitled to pay for the time he spent in getting it from the producer to the consumer.

He instructed me to put this honey up in crates holding from 100 to 112 pounds, according as the sections were completed by the bees. When delivering the second load, a day or two after the first delivery, I found him sorting the honey I first brought, and putting the different grades into different-sized crates or cases, and sending each to his different customers in the different cities, in accordance with what any particular market called for.

HIVE PROTECTION.

The Temperature of the Hive Outside the Cluster Nearly the Same as that Outdoors; Thin Hives Covered with Black Paper Better than Expensive Chaff Hives.

BY ARTHUR C. MILLER.

Some years ago I brought to the attention of bee-keepers the value of black water-proofed paper as a winter and spring covering for hives, and explained some of the reasons for its usefulness, and some of the things to be guarded against. Several, evidently thinking that I erred in some of my methods, or overlooking some of the directions, proceeded to use it contrary to some specific and emphatic instructions. They came to grief, and promptly laid it to the black paper. Others thought any water-proof paper would do, and failed to secure expected results in its use. Still others, thinking to improve on all the rest, covered their hives with several layers of papers, and then put a telescope cover snugly over it. All failed to grasp the fundamentals.

Many bee-keepers now have hives either paper-protected or are planning so to protect them in the spring on removing the bees from the cellar, and it may be helpful to repeat at this time some of the essentials, and emphasize some of the important details.

First, a description of conditions within the hive in winter and spring is necessary. In a normal colony of average size, and which has not been unseasonably meddled with, the cluster will be found in early winter down close to the entrance. If such a cluster is opened and examined, it will be found to be nearly spherical in shape, and usually the cells within the sphere contain each a live bee; and between these bee-filled combs other live bees are solidly packed; so, except for the thin waxen cell walls, there is actually a solid living ball of bees. About the outer part of this cluster unsealed honey is found, and beyond that the sealed.

If into that ball, and in the spaces between the combs beside, behind, above, and below the bees thermometers are thrust, some surprising things will be revealed. For this purpose long slender thermometers with long straight bulbs are used. These are passed through holes bored in a super cover, and the cracks about the glass stems are stuffed with cotton. The scales of the thermometers are on white glass backgrounds made a part of them. These scales are selected so that the range of degrees probable will be above the level of the super cover. Over these protruding glass tubes is placed an inverted box or similar cover. This may have glass windows to read the scales through, or the box may be lifted off for the purpose.

As soon as the bees quiet down from the disturbance caused by thrusting the ther-

mometer bulb into their midst, a temperature of 68 to 72° F. will be found. Outside of the cluster, before, behind, or beside, the temperature will be about the same as out of doors. If external temperature has been nearly level for a day or two, the internal temperature will be not over one or two degrees higher. Just above the cluster the temperature will be but a few degrees below that of the cluster center.

These facts are the same whether the hive has walls stuffed with three inches of sawdust or chaff, or are only half an inch thick.

Now, if the thermometer within the cluster is wiggled, the mercury begins to rise; and within five to eight minutes it has risen ten to twelve degrees. Remember this, for it shows the cost of disturbance of the bees in winter. That increased heat is expended energy—bee life plus honey.

If the bees are in thin-walled hives the temperature within the hive (and outside the cluster) will closely follow that outside the hive. In chaff hives, particularly with small entrances, the fluctuation is slower, and this is to the disadvantage of the bee-keeper. If a blizzard has been raging, or strong winds with low temperature have prevailed for several days, and then there follows a still sunny day with a considerably milder temperature, the inside of that "nice warm chaff hive" is not pleasant to contemplate. It is just as cold in there as it was out of doors when the storm was raging, and it stays so for a long time. On the other hand, after an extended period of milder weather the temperature inside reaches the same level; and if a cold spell follows, the inner temperature falls slowly. But winter "mildness" is a long way below cluster temperature.

Bees in the thin hive get *more rapid change of temperature, but no greater extremes*. If the entrance to their hive is sufficiently large, little or no moisture will collect on walls or combs. If the entrance is small, moisture may collect; but the first mild and sunny spell will dissipate much of it. But not so in the thick hive. If moisture collects in it, it stays.

Just as soon as brood-rearing begins, internal conditions undergo a change. Cluster temperature rises; and when the brood occupies part of two or three combs, much more moisture is given off.

The exact temperature change within the cluster after brood-rearing is well under way is as yet a matter on which the several investigators are not agreed. Some note a regular rising and falling of about ten degrees each day, the rise beginning about 10 A.M., reaching its maximum in about an hour or a little more, remaining level until nearly 1 P.M., and then dropping until it reaches minimum at about 2 P.M. This is designated as a feeding fluctuation. Other observers noted the rise of only about 18° F. from the minimum of no brood, so that, in

the presence of brood, the temperature of the cluster stands steadily at about 88° F. And thus matters remain until the cluster "breaks."

When the bees cease to pack into the cells and spread out over the combs (break cluster), conditions within the hive are materially changed. Every thermometer will give nearly the same reading (if the colony is normal); those next to the brood, reading a little above the others. In other words, the bees are keeping the whole chamber warm, and the chaff-packed walls become a very decided help to the bees.

The bees in the unprotected thin-walled hives can not keep the whole brood-chamber warm, so that, from the "breaking of the cluster" until settled warm weather, they are kept much behind colonies in protected hives. But if a single-walled hive is properly covered with a *black* water-proof paper, the results are even better than in the more expensive and more cumbersome chaff hive. Paper to be "properly put on" should be so adjusted that no drafts can enter or leave the hive except at the entrance, which should be left open to a size not less than one by fourteen inches.

Before brood-rearing commences, the temperature within a hive thus protected fluctuates more widely than out of doors, and with this difference: When the sun shines, the black paper absorbs much heat; the hive is warmed through, and the condensed moisture is dispelled. As the season advances and the sun gets higher, the increase of temperature within becomes greater, even up to a point where the bees are incited to considerable activity. If now the entrances are small, the whole chamber becomes so warm that the bees will come down and start out as in summer, only to plunge into a chilling atmosphere without, and perish. But if the entrance is as large as indicated, when the bees reach the bottom of the frames they encounter a stratum of cold air, and, hesitating, start out slowly, if at all.

When the sun passes, the radiation from the paper-protected hive is slow—very much slower than the absorption of heat from the sun. When the cluster finally breaks, the bees can keep this hive as warm as the chaff-protected one. And they have the additional help of the sun's heat which is absorbed by the black paper.

There is a vast difference between a hive painted black and one covered with paper that is black. But where a thin telescope cover is used, and that is covered with black paper, all the advantages of the paper-covered hive are secured with the additional advantage of convenience and permanency. Only two additional items have to be considered with it—namely, having it deep enough to cover the whole hive-body, and having some sort of weather-strip around the bottom edge so air can not blow up under it.

In the spring, after the cluster breaks, it is safe to contract the entrance to suit the owner's fancy; but experience has shown

that no real gain was made by such procedure, if the colonies were of normal size.

Providence, R. I.

[When we received the above article we felt that the importance of the question at stake was such that the other side should be presented at the same time; accordingly we sent a copy of it to Mr. Holtermann and Mr. Byer. Their replies follow.—ED.]

HIVE PROTECTION.

Though the Temperature Outside the Cluster of the Interior of a Thin Hive with a Large Entrance May Vary Little from that Outdoors, does this Prove that Ample Packing is Useless?

BY R. F. HOLTERMANN.

STORES.

Mr. Miller says, "If such [a natural colony of average size] is opened and examined, it will be found to be nearly spherical in shape, and usually the cells within the sphere contain each a live bee, and between these bee-filled combs other live bees are solidly packed; so, except for the thin waxen cell walls, there is actually a solid living ball of bees. About the outer part of this cluster unsealed honey is found, and beyond that the sealed." It is a mighty difficult matter to say what "a normal colony of average size" is; but the description which follows would, in my estimation, picture a colony not well equipped for winter. (It may be insisted that, as I use a large hive (twelve-frame Langstroth), and do not allow my bees to swarm, a description of my bees would not give an average colony. Let me say that there are many bee-keepers who have adopted this system, or are aiming at it with a large measure of success, and many more are convinced of the economy and desirability of such a system, but do not yet know how to make a success of it.) I will guarantee now in early January (for I have had such for years) to take a committee to some of my apiaries in the early spring and show them many colonies that have bees on all of the twelve combs—colonies which ran in weight, without cover, 100 lbs. or even more in the fall of the year. Such colonies we all know must cover a very considerable portion of the capped honey in the fall and early winter. Colonies and their stores should be so arranged that they cover as nearly as possible all of the winter stores in the hive, as stores not covered by the bees during cold and damp weather deteriorate, and so much the more if there is much entrance or other opening to allow of the free circulation of air. It does not take a very good judge of honey to distinguish between honey which has been covered by the bees and that outside of the cluster in the hive during the winter months. The uncovered stores simply absorb moisture and atmospheric impurities, and granulate or deteriorate.

If I have to feed, and have only a limited number of colonies to prepare, I would not feed until close to the time when we *may* have permanent cold weather. I would give a syrup made of $2\frac{1}{2}$ lbs. of granulated sugar to 1 lb. of water brought to a boil; and if I wanted to do what I felt sure would be the best, I would add a teaspoonful of tartaric acid to each gallon of syrup. There is then little need of evaporation by the bees, and they would store the syrup in the midst of the cluster. No better stores can be provided for bees during winter confinement. In my estimation, if a bee-keeper has only an early surplus-honey flow such as clover, his bees are really never in a proper condition for best wintering without feeding; because if they have enough stores in the hive (which, as a rule, is not the case), it is not in the place where the bees can keep it in the best condition.

TEMPERATURE AND ENTRANCE.

Mr. Miller says, further: "Outside of the cluster—before, behind, or beside, the temperature will be about the same as out of doors. If external temperature has been nearly level for a day or two, the internal temperature will be not over one or two degrees higher. Just *above* the cluster the temperature will be but a few degrees *below* that of the cluster center" (italics are mine). This, he states, is 68° to 72° . This, no doubt, will be correct if the bee-keeper follows out his direction as to size of entrance, "which should be left open to a size not less than one by fourteen inches." The object in leaving the large entrance as stated by Mr. Miller is, "If the entrance is small, moisture may collect." Just so; and that is one reason why I do not want the water-proof paper over the hive, for it means that the moisture and foul air must all come out at the entrance, or in part condense on the stores. The fresh air and foul air, by this method come out at a common low-down entrance. In other words, the oxygen to assist the fire to burn, and the smoke and exhaust air, all go in and come out at the damper of the stove. Such a system is not based on scientific principles.

The entrance of the hive can be very small in winter. The entrance to my hive is $1\frac{1}{4}$ inches deep by the full width of the hive, 19 inches. I used to keep, during hot weather, a pair of wedges, $\frac{7}{8}$ in. deep, at the front of the hive, running to nothing an inch from the back, these placed between the sides of the bottom-board and the side of the hive. They were removed when the robbing season set in. I now have them as a permanent fixture the year round, and contract the entrance to suit my needs by a reversible entrance-board to fit lightly between the sides of the portico, $2\frac{1}{2}$ in. deep, and $\frac{1}{4}$ in. wide. Dividing this board by an imaginary line parallel to the bottom-board into two equal parts we have two parts, each $1\frac{1}{4}$ in. wide. The one has on the outer edge an entrance 6 in. long by $\frac{1}{4}$ in. high. The other, outside, an entrance 4 in. long by $\frac{1}{4}$ in. wide, and three holes next to the imaginary line

—one in the center lengthwise, and the other two one at each side about $2\frac{1}{2}$ in. from the center hole. These holes are $\frac{3}{8}$ in. in diameter. During the fall I turn next to the bottom-board the 6-inch entrance. When I pack for winter I turn the 4-inch entrance down. The three $\frac{3}{8}$ -inch holes now come just below the front board of the hive. Before, with the 6-inch entrance, they were closed by the front board of the hive, as they are not in the center of the board. Dead bees can not close these round holes until they accumulate to the depth of one inch on the bottom-board, which does not happen as long as the colony is worth saving.

By putting a piece of lath in the bridge in front of the entrance I can, by reaching with a wire through the three $\frac{3}{8}$ -inch holes in the outer case, close the lower 4-inch entrance quite or almost entirely.

The fresh air in moderate quantities enters the well-protected entrance (the holes in the outer cases are not on a level with the $\frac{3}{8}$ -inch holes in the entrance board or block to check drafts). It ascends about the bees; and as it is being warmed it keeps rising, taking with it moisture and impurities, finally passing out of the hive above. The exit is expedited by a queen-excluder resting on each hive, with a cloth on the queen-excluder. In this matter I have followed the advice of Jas. Armstrong, one of Ontario's efficient inspectors. The air with the contained moisture and impurities passes through the leaves, 8 to 10 inches deep above, and condenses on the cold $\frac{1}{2}$ -inch cover, with roofing-paper outside above, or passes out of the case through ventilators for the purpose.

With such a method no one need tell me that the temperature inside the hive, about the cluster, is, in a more or less short time, the same as that outside. I am quite free to admit that much (almost all) the advantage of packing is lost when a heavy cold wind strikes the entrance of the case. But I have an 8-ft. fence about a small piece of ground, and I feel very strongly that any other method of caring for bees outside is a mistake—sometimes a calamity.

LOSS OF HEAT, THEREFORE VITALITY OF THE BEES, PLUS HONEY.

Mr. Miller himself furnishes an excellent foundation for opposing his conclusions in the statement, "If a blizzard has been raging, or strong winds with a low temperature have prevailed for several days, and then there follows a still sunny day with a considerably milder temperature, the inside of that nice warm chaff hive is not pleasant to contemplate;" and he tells us, "Just *above* the cluster the temperature will be but a few degrees *below* that of the cluster center." *There is the point.* This is clear proof that there is a certain amount of heat given off by the cluster of bees. From Mr. Miller's experiments I find it is even more than I expected it to be. This heat given off by the cluster has an effect upon the hive, and a much greater effect if the entrance to the

hive is small and the bees are *well* protected by packing, but is rapidly lost with an entrance in the winter and spring, 1 in. by 14 inches. The heat passing away more rapidly compels more heat to be generated, which, as Mr. Miller rightly states, "Remember this—that increased heat is expended energy—bee life plus honey." If we have a stove (the cluster) in a room (the hive) it makes a vast difference if we open the window half an inch or take the window out altogether (my winter entrance in contrast to Mr. Miller's).

It seems to me that, however sound the argument may seem to some, an overcoat to keep out the cold is a good thing to keep out the heat, or that no overcoat is a good thing in the morning because the sun can strike us better later in the day to warm us up. As with us, so with the bees—the natural heat of man and bees has to be considered.

SPRING.

In spring, hives protected as mine are, the bees are active in the hive feeding brood, and the queen laying, when in unpacked hives about all they appear to have the energy to do is to turn up their tails slowly, let their stings protrude, and give the well-known accompanying buzz. Perhaps in Mr. Miller's locality the temperature does not range very low nor last for any length of time. The protected entrance also almost entirely prevents robbing, and also keeps the bees from coming out on the least provocation.

Brantford, Ont., Canada.

THE RESULTS OF SOME EXTENDED EXPERIENCE IN CANADA.

Colonies in Thin Hives Wrapped with Paper Died, while Others, Wintered in the Same Yard in Packed Hives, came Through in Good Condition.

BY J. L. BYER.

I have had some considerable experience in the matter of wintering bees outdoors in our severe Ontario climate; and whatever I shall say will, of course, be based on that phase of the subject. And right here let me say that I know nothing of what the climatic conditions of Rhode Island may be, and, for aught I know, Mr. Miller's papered bee-hive may be all right for that State, and countries in a similar latitude. At the same time, I can not understand how it is that what is good for us in a colder climate would not to a lesser degree be good for a milder one, where, even if the thermometer does not go as low as it does here in Ontario, there are nevertheless very sudden changes from cold to warm, and *vice versa*.

As Mr. Miller says, some few years ago he boomed the papered-hive idea in the *American Bee-keeper*. Well, I myself was one who tried to save a few dollars at a time when a silver quarter looked as big as a

"cart-wheel," and as a result I got "stung" in good shape. In glancing at the sub-heads of Mr. Miller's article I notice the phrase, "Thin hives covered with black paper better than expensive chaff hives," and the thought came to me that, if such is the case, a number of bee-keepers who have no money to throw away are making fools of themselves in going to the trouble of giving lots of protection to their bees when a common hive wrapped with a few farthings' worth of paper would answer the bill *better* than all the protection (?) we are giving them. Among the number, the names of McEvoy, Holtermann, Sibbald, and Miller come to my mind, and these four men winter colonies by the hundreds outdoors. Counting in my bees, the five of us winter probably 2000 colonies, so the expenditure in the way of protection, as we now understand the term, amounts to no small sum in the aggregate. Many others might be named, but these names happen to come to my mind as being associated with outdoor wintering quite prominently.

Now, as I have already intimated, I propose to speak on this matter from the standpoint of experience; and in order to get directly at the subject I will at once tell how the plan as advocated by Mr. Miller worked here in Ontario during a winter such as our grandparents designated an "old-fashioned" one. Having a number of colonies in single-walled hives that had to be looked after in some way in order to carry the bees over the winter, friend Miller's plan that appeared in print just at that time was eagerly taken advantage of as a method that would help me out and at the same time solve the question of winter protection when I had no money to buy winter cases. The hives were prepared (about 20) as nearly as possible according to Mr. Miller's direction, with the exception that not quite as large an entrance was given as he specifies in his present article. As a matter of fact, he says an entrance should be not less than one by fourteen inches, and of course this would be impossible in an eight-frame hive. However, I want to be perfectly fair in the matter, and I will admit that the entrances I gave were not as large as they *could* have been in an eight-frame hive. Indeed, an entrance one inch deep, full depth of hive, would allow the hives to be pretty well filled with snow during some of the storms we have sometimes. The hives used were eight-frame; but the frames were somewhat deeper than even the Jumbo size—a circumstance that favors outdoor wintering more or less, as the deeper frames are generally conceded to be somewhat better for wintering than the standard L. frame.

As nearly as I can recall from memory, the entrances were one inch deep, and varied from five to eight inches in width; but I can not for a moment think that a few inches more in size of hive entrance would have made any radical differences in the wintering results.

As already stated, the winter was a very

cold one, so I had abundant facilities for testing the two styles of winter protection as mentioned by Mr. Miller, as in the yard were also about 80 colonies wintered in packed hives. After quite a long spell of cold weather it was found on examination that the sides and ends of the paper-packed hives were coated with frost very heavily, while in the packed hives very little was found on any hives, while many showed none at all. Now, I am well aware that a cluster of bees, to a wonderful degree, can prevent radiation of heat from the cluster, yet *some* heat must leave the cluster, else how could the condensed moisture on the sides and ends of the hives be explained? Then if the packed hives were no warmer than the papered ones, why the absence of frost on the sides and ends, when on the walls of the papered hives the frost was so much in evidence? Mr. Miller says that, if moisture does collect in the hive, the first mild and sunny day will dissipate much of it. On the hives I have under discussion, when a mild day came the moisture would run in streams out of the entrance and would often freeze there toward evening or at a time when the sun would not strike the front of the hive. All winter they gave me trouble, and before the winter was half over I knew that it was all up with the most of them, and the following May only five or six were alive, and they were only weaklings at that. How about the other 80 colonies wintered in packed hives? Writing from memory, the bees wintered in perfect shape with only the loss of three or four colonies from queenlessness, etc. Why the difference in results, if the manner of packing was not the main essential in the transaction? At the time, I said something about my experience, in one of the journals, and Mr. Miller said that he did not recommend the plan for our Ontario climate. In his present article he makes no exception to climatic conditions; and as thousands of colonies are wintered outdoors in our latitude, he probably thinks the plan he recommends will be all right wherever bees are wintered successfully outdoors.

Regarding the temperature of the hives away from the cluster, it seems quite reasonable to believe that the air would be as cold inside as outside in a hive with no protection except paper, and with an entrance 14 inches long and 1 inch deep. That is on a par with opening the door of our living-room during zero weather.

When it comes to protected hives, then I will assume the "show me" attitude till I am convinced. Go to one of the winter cases with four colonies packed close together inside, as described by Mr. Holtermann in a recent article in GLEANINGS. Lift off the packing from the tops of the hives and note all four clusters in a circle around where the four hives meet one another. See the entire absence of frosty walls (provided there is ample protection of dry material between hives and case) and dry condition of the combs; and if you are not convinced

that the air in such hives is warmer than that outside of hives, it will only be when a thermometer under proper conditions has proved otherwise. As to the absence of frost on the walls of the hives, possibly the absorbent material around them accounts for the difference. The main thing I look at is that it is *absent*, while on the papered hives it is always present in very cold weather.

I have tried the black paper for spring protection; and when I say that, besides the bees wintering outdoors, I have 300 colonies inside, and would not thank anybody to paper the whole outfit gratis when they are taken out in the spring, anybody can understand my position on the question without going into detail. My main objection is that the black paper around the hives warms up the hives too much during sunshine and causes undue disturbance, the bees flying out only to perish outside. Mr. Miller covers this point by insisting on large entrances; but as I do not like an entrance in the spring as large as specified by him, the difficulty I mention could not be overcome. Some packing *over* the brood-nest in the spring is, in my estimation, worth more than many sheets of paper around the sides and ends. I have wintered bees in hives prepared as he says, even in our climate, and they sometimes came through fairly strong. But when such was the case, the winters were not as severe as the one during which we lost so heavily.

Another important matter is that every colony wintered with the *minimum* of protection consumed a *maximum* of stores, so in the end any apparent saving in the cost of winter cases was more than made up in increased consumption of stores and weakened vitality of the bees. For seven years in succession I wintered a strong colony in a very large hive, with no protection except packing over the top inside of a super. A hole near the top of the hive would allow me to see the cluster in zero weather, and they wintered well every winter in spite of no protection; but they always consumed about twice as much stores as the protected colonies. While seasoned bee-keepers in climates like ours are not likely to try doing away with protection for their bees, there is danger of some fellow doing as I did some years ago; and all such I would urge to go slow, and test the matter well before risking too much.

Very strong colonies with a very large amount of good stores will winter any old way; but, generally speaking, the apiaries given the best protection during the winter and spring will give the best results in the honey-flow; and I feel pretty sure that, if Mr. Miller were in our locality, and wintering outdoors, he would soon modify his statements as to the relative values of papered hives, and hives in cases with abundance of dry material to protect from the cold winds and take up any moisture that may collect in the hives. If experience proved otherwise, I would be one of the first to quit

spending money for something worse than useless.

Mr. Miller says that "bees in the thin hive get more rapid change of temperature, but no greater extremes." I agree to the first clause of the statement unreservedly, but dispute the second just as strongly. During very cold days in the latter end of January and early in February, whenever the sun would shine brightly for a few hours the bees in the paper-covered hives would be warmed up to such an extent that the clusters would be broken more or less, and the bees become quite uneasy. This condition repeated at various times was a factor that worked havoc to the bees in these *thin hives*, while such short periods of sunshine did not affect the bees in the packed hives, for they wintered in splendid condition.

THEMOMETER READINGS SHOW AVERAGE
DIFFERENCE OF 35° BETWEEN OUTSIDE
AND INSIDE.

Jan. 5 gave signs of a real cold wave visiting us, so a hive was selected for an experiment. The hive is a very large one—12 frames, L. length, and somewhat deeper than the Jumbo style—what some would call a veritable barn. It is a regular packed hive with a double bottom, two inches of sawdust being between the case and hive proper. The outside case is of half-inch stuff. The entrance is $\frac{1}{2} \times 10$ inches, lined inside with paper, and then there is a filling of four inches of dry sawdust between the case and inner hive of inch material. Over the frames is a porous quilt, and on top of that two sacks; without, ten inches deep of sawdust and chaff mixed. Over that is a roof of galvanized iron, and between roof and packing is an air-space of ten or twelve inches. The hive has ten frames and a division-board, which leaves a space of one frame at the side of the hive unoccupied. The division-board was shifted to the outside, and the thermometer suspended between it and the outside comb. The colony is strong, and occupied seven spaces when the weather was at zero, no bees being next to the comb beside the thermometer; but the fringe of the cluster reached to the next space. All that was necessary to do to see the thermometer was to lift off the gable cover quietly, turn back the corner of the sack with the packing, and lift the corner of the quilt. Friday afternoon the temperature had reached zero, and was on the down grade. The thermometer was put in the hive at 4 P.M. The following are the readings for three days in succession.

Saturday, 8 A.M.—Very clear and quiet; 15 below zero outdoors; inside the hive, 34 above. Saturday, 5 P.M.—Zero outside; 40 inside hive; sun had shone brightly all day. Sunday, 8 A.M.—Zero, cloudy all day; inside hive, 35. Sunday, 5 P.M.—1 below zero outside; 36 above, inside. Monday, 8 A.M.—Stormy; cold wind blowing right in the entrance all day; 4 above zero; inside hive, 34 above. Monday, 5 P.M.—16 above, outside, and 36 above in the hive.

Mt. Joy, Ont., Can.

[With a large entrance on one side of the cluster, a single-walled hive, and only one thickness of tarred paper around the hive, we should hardly expect the temperature inside to be very much different from that on the outside. In order to determine the conditions in and outside of a *double-walled packed hive*, with 7 inches of packing on top and $2\frac{1}{2}$ between the walls, we took a number of temperature readings at our home yard. A series of colonies in such hives were selected at random. A thermometer was placed in different parts of the brood-nest, and in one case in particular it was let through a hole in the super-cover, the upper portion sticking up into the packing, so that a reading could be taken without opening the brood-nest. Here are some of the readings we took off where the cover and packing was removed and the thermometer examined before the mercury could possibly change:

Jan. 3, outside, 22 F.; inside temperature of first hive, 60; second hive, same day, 58; third hive, same day, 50; fourth hive, 50; fifth hive, 63. In explanation of these variations we would say that the temperature would have been the same in all the hives within one or two degrees if the thermometer had been placed the same distance from the cluster. In hives 1 and 2 the bulb of the thermometer was placed within two inches of the cluster, and hence the higher reading. On Jan. 5, with a temperature of 7 above, we bored a hole through a super cover, placing the bulb of a tested dairy thermometer clear to the back end of the hive as far away from the cluster as possible. Here are the readings: In the afternoon, about five hours after the thermometer was inserted in the hole, a reading was taken that showed 7 above outside, and 26 inside. Jan. 6, 7 A.M., the outside temperature was 5 below; inside temperature, 20 above. On the same day, at 2:20, the outside temperature was 10 above; inside temperature, 28. Jan. 8, outside temperature 29 above; inside, 28. But on that day the temperature outside rose rapidly from zero in the morning to 29 above. It is, therefore, plain why the inside should have been 28. But right here our experience teaches us that rapid changes of temperature inside of the hive for this locality are detrimental, because they break up the cluster, causing excitement when the bees should be kept quiet. Again, Jan. 8, the outside temperature was 4 above; inside, 28 above. As we are located in a warmer climate than Mr. Byer we do not use as heavy a packing. Perhaps it would be better if we did, for we notice that his inside temperatures are relatively higher. Rhode Island has a milder climate, and much more moisture than most northern localities near the great lakes, and it is no doubt true that it is an advantage to have large entrances; but we can not get away from the conclusion that more packing would save a considerable amount of stores. See further comments on this question in the Editorial department.—ED.]

BEE-KEEPING ON THE APPALACHICOLA RIVER, FLORIDA.

Locating Whole Apiaries up on Stilts or Benches, above the High-water Mark.

BY E. R. ROOT.

In our previous issue I told you something about the wonderful possibilities in the way of honey production along the banks of the Appalachicola River, and I promised to take you to some of the apiaries where the hives are located clear up in the air on benches above the high-water mark of the river. Before doing this I wish to introduce to you our host, Mr. A. B. Marchant, whose apiaries we have been visiting, and whose methods for taking honey we have been considering. He is only slightly older than myself, and that means he is still a young man, of course, even if I am within five months of being half a century old. I do not need to say any thing more about Mr. Marchant as a bee-keeper, more than to mention that he has taken as high as 250 barrels of honey in 26 days. A man may know how to spin fine theories. He may be, indeed, a fine bee-keeper; but unless he can make those theories and that expert knowledge pan out into *results*, he is not a successful bee-keeper. Mr. Marchant is not only a bee-keeper, but a honey-producer. 'Nough said.

He invited me to take a trip with him down the river in his gasoline-launch, and, of course, I accepted the invitation. In this Appalachicola region an automobile would be out of the question, mainly because of deep sand and lack of roads; but a gasoline-launch is almost a thing of necessity, for with it a bee-keeper can visit his yards as often as he pleases, and haul his supplies and honey back and forth with the greatest convenience.

We walked down the wharf where we saw those big loads of honey, and stepped aboard

A. B. MARCHANT.

his launch called the *Dixie*, and glided out into the river, the engine going "tuppy, tuppy," as we went. The water is clear and deep, and the fishing superb.

As the little craft goes down the stream toward Appalachicola, beautiful scenery opens up at every turn of the river. Here and there a little stream empties into the big one, and up almost any of them one can find a good place to locate a bee-yard, providing, of course, he has the money, and time to put his apiary up on platforms, six, eight, or ten feet above the ground. As we sat in the bow of the boat Mr. Marchant

pointed out the tupelos along the river. I said:

"Mr. Marchant, why don't we see more bee-yards in this country?"

"Largely," said he, "because there are few places in which to put bees."

The banks of the stream are heavily covered with timber. Occasionally here and there one may no-

Marchant's gasoline launch for going to and from bee-yards and to town.

R. L. Tucker's apiary on the Appalachian River, elevated upon platform to avoid high water.

tice a clearing, but the ground is swampy and low, and therefore it becomes necessary for some who do locate here to go to considerable expense in making the elevated platforms, with a runway between the hives. Let us stop at one of these yards.

The subjoined illustrations show the apiary of Mr. R. L. Tucker, who has his post-office at Appalachicola. Here we see 360 hives of bees located clear up in the air. The different views will show the details of construction of the platforms and the convenient runways for a wheelbarrow down between the rows of hives. Notice how the platforms are braced, and that the hives are set up on side racks, I should say two feet above the general runway. When the plat-

forms are finally constructed Mr. Tucker has a location for a bee-yard as good as he can ask—no grass, no weeds, no shrubbery—just nice board sidewalks to every hive.

At one end of the "apiary," and also on stilts, is a small building where the owner himself can eat and sleep, put together his supplies, put in foundation, extract his honey, etc. At the time of my visit Mr. Tucker had been sick a few days—whether from malaria or what, I do not know; but, unfortunately, this low marshy land, while it may be ideal for an apiary up on stilts, is, apparently, not an ideal place for the owner to spend several months during the height of the season; and this may explain why there are not more bee-keepers in this coun-

Tucker's apiary, showing the detail of the high benches.

The handy board sidewalks between the hives.

try that furnishes, I might say, shiploads of honey, much of which is now going to waste.

Again we board the launch. As we go "tuppy, tuppy" down the stream we find other bee-keepers located a good deal like those already shown. For example, Mr. B. F. Tucker, at Bluffston, has between 250 and 300 colonies.

As we hasten down toward Appalachicola we make no more stops. But I said to myself, "If it were not for malaria and mosquitoes, this would be the greatest bee-keeper's paradise I ever struck in all the United States, and I have now traveled nearly every foot of territory where bees are known to thrive." I doubt if this country will ever be overstocked.

Our friend Mr. A. B. Marchant, at Marchant's Landing, must be better located than most of the bee-keepers on the river. He is on comparatively high ground, on good land where he can do any thing else he pleases. Unfortunately our friend has suffered severely from two fires, losing his home in both cases, and, unfortunately, his business has increased to such an extent that he finds himself with too many irons in the fire. Besides a sawmill, bee-ranch, and orange-grove, he is also extensively engaged in queen-rearing. As we went down the river out into the Appalachicola Bay he showed me islands off in the distance where queens could be mated to choice drones. He has not worked out the scheme yet, but hopes, before another season rolls by, to furnish island-bred queens mated to choice hand-picked drones. The islands are just far enough from the main land to furnish ideal conditions. If he can possibly get the time he will give us the benefit of his experiments along this line.

I can not drop this Appalachicola district without referring to one or more prominent bee-keepers in that section, whom I was unable to visit at this time. For instance, there is Mr. S. S. Alderman, at Wewahitch-

ka, further up the river. At one time he had as many as 1500 colonies, but now he has only 1000. He does not employ a number of men to work for him, but farms his bees out on shares.

THE BEE-STING CURE FOR RHEUMATISM.

[The following letter was sent to Mr. Fred W. Muth, who, because of the widespread interest shown in the bee-sting cure, sent it on to GLEANINGS together with his reply.—ED.]

I am a sufferer from arthritis (chronic rheumatism) of the joints—some call it rheumatic gout. I have just read the article in *Country Life in America* for December on your application of the bee-sting on Mr. Renner's arm for his rheumatism. I decided, at any rate, to trespass upon your courtesy and ask for your opinion, as you have had experience. We have few bees near by. Is the sting of all species of bees equally efficacious? about how long a time is required to inoculate the system with the formic acid from the bee? I have a long vacation in the summer, and I am wondering if I could have you get your bees to work on me next summer? I would gladly meet any reasonable expense. Please advise. I have little or no rheumatism in the muscles—all in stiffened, swollen joints. Could the sting be applied there? I have tried all known remedies, but nothing is of the least service. I am ready for something heroic, and sincerely trust you will do a sufferer from a terrible disease the courtesy of telling him whether you would be willing later to try your bee cure on him.

G. PRENTICE CARSON.

De Land, Fla., Dec. 8.

[The writer is not a specialist on this subject, and can not advise whether all kinds of rheumatism can be cured by bee-stings. On the other hand, were I a sufferer from rheumatism as you are I would surely try

Forsythe's queen-finding sieve that slides in the entrance of the hive.

stings, for it costs nothing, and the writer believes it will do more good than harm, and harm it can not do, for we have never known a practical bee-man to be afflicted with rheumatism. Some fifty years ago my father was a terrible sufferer from this dread disease, and purchased some bees for the express purpose of curing his rheumatism, and was never troubled afterward. It is the occasional sting while working with the bees that does the work.

Mr. Renner, in question, came to our apary last spring of his own accord, as the last resort. For fifteen years he had been unable to work. Since the cold weather has set in he has not made his appearance, but has called up our office and tells me he has not felt better for many years, and that he is coming back next spring, for he firmly believes he will be entirely relieved.

If you will be the possessor of a few colonies of bees, and do the work among the bees yourself, we feel you will be most handsomely rewarded in your health.

FRED. W. MUTH.

Cincinnati, Ohio, Dec. 11.

QUEEN-FINDING SIEVE TO FIT IN HIVE-ENTRANCE.

BY ROBERT FORSYTH.

I am sending you a photograph of my queen-finding sieve as described on page 666, Nov. 1. I have given it a thorough trial, and do not see how any thing could be more simple or effective. When the sieve is slipped under the frames and the latter are shaken in front of the hive, no opportunity is given the bees to reënter the hive except through the sieve. When all

have entered, pull out the sieve and you are sure to have the queen.

Clairemont, N. H., Oct. 30.

BEE-KEEPING IN ENGLAND.

BY A. H. BOWEN.

Thanks to the influence of "Old Sol," who shone out in cloudless skies from early morn till dewy eve, the year 1911 ranks high in England among the seasons of recent years, for both the quality and the quantity of the crop are excellent. Indeed, had it not been for the stormy period in June and the fierce heat of July, the season would have been a record one; still, the result is satisfactory and most encouraging after two poor years.

With a fairly mild winter, bees came out in good condition, but the early spring proved unfavorable, and was bitterly cold, with the result that many colonies died out through lack of bees and stores.

This condition existed until the end of April, when the weather changed; and from then right on we enjoyed perfect bee days. Fruit-trees rapidly came into blossom, and colonies quickly built up until, at the beginning of June, many were on fourteen combs of brood, and occupying two supers.

All colonies located on the hills where the first flow is from sainfoin, were fed with syrup from about March, right on until the honey-flow. The syrup was given in slow tin feeders, and it was surprising how powerful the colonies became, just in time for the flow, which commenced early in June. A large quantity of unusually light honey was stored and quickly extracted, the wet combs being returned ready for the main clover harvest.

Two-foot log split open, exposing large colony of bees.

Unfortunately, the weather broke up and continued showery and cool until July, when we again enjoyed a glorious period of sunshine, which lasted more or less until the end of August. The fierce heat somewhat scorched up the clover; but a fair quantity was collected from that source, and also from the lime-trees, which yielded well this year. From my own bees I secured an average of 35 lbs. per hive of comb and extracted honey, and also obtained a 25-per-cent increase. The strongest colony yielded 100 lbs. of extracted honey; the next, 85 lbs.; and from the remainder, quantities varying down to 10 sections.

When getting wet combs cleaned up after the last extracting I have found it advantageous to place them *under* the colonies instead of above, as is usually practiced. My method is to remove the colony from its floor-board, and put on two or three supers containing wet combs, then replace the colony on the top. The entrance is contracted to avoid robbing; and when honey has all been carried above, the supers are removed.

In this country bees are usually covered with quilts made of a coarse material such as felt carpet, or even cast-off garments; but I use a wooden quilt of my own manufacture, which answers the purpose admirably; for not only does it afford protection against both cold and damp, but it also provides a perfect winter passage. The excellent way

in which bees winter when covered with this quilt has proved to me its very great value. I should like to convey to your readers some idea of the quiet beauty of the Cotswold, especially in September. Nature is then at her best; the cold bleak hills are clothed with the warmth of golden stubble, and the autumnal haze softens the landscape with those lights and shades which add so much of loveliness to a hill country; and suddenly, as we ramble along, a lovely valley is seen below; old-world farmhouses and ivy-covered cottages come into view, nestling among stately elms and beech-trees. On descending we come into a typical Cotswold village, with its manor house and Norman church, which stands out against the russet-tinted woods in the background. Passing through the village you will come across here and there in the cottage garden half a dozen skeps raised from the ground on logs of wood, and covered with a miscellaneous assortment of crocks, old sacks, tins, or any thing else which can be pressed into service. With the "gentlemen that pays the rint," and the proceeds from the sale of honey, cottagers are able to supplement their somewhat scanty wage.

But the great changes which are sweeping over our land have already invaded even such secluded Cotswold villages as these, and very soon the skep and thatched cottage will be a thing of the past.

Cheltenham, Gloucestershire, Eng.

A LARGE COLONY TAKEN FROM A TWO-FOOT LOG.

BY A. W. AAMODT.

Inclosed you will find a picture. This view of the split bee-log shown herewith was taken during the fore part of October. After some hard work we managed to get this log cut from a bee-tree which was two feet in diameter. We saved the bees and got a good strong colony. We gave them combs containing about 20 lbs. of honey, and, besides that, we got 19 lbs. for home use. The bees were hybrids, but we introduced a pure Italian queen, and by next summer we shall probably have a pure Italian colony.

St. Paul, Minn.

MEETING OF THE NORTHERN CALIFORNIA BEE-KEEPERS' ASSOCIATION.

A Plea for a State-wide Association.

BY W. A. H. GILSTRAP.

The sixth annual convention of the Northern California Bee-keepers' Association was held in Sacramento, Dec. 27 and 28, 1911. It was one of the most important meetings of honey-producers ever held on the coast. A veteran in the pursuit, who was unable to attend, thinks there have been few if any conventions of honey-producers in the United States which has had so beneficial results

as this one will have. To understand the situation, some historical evidence should be introduced.

Over twenty years ago the Southern California Bee-keepers' Association was formed, the projectors trying to interest those further north in the work. The name was soon changed to California State Bee-keepers' Association, and the effort continued to get all honey-producers in the State to combine. The writer knows this is fact.

Not much later the Central California Bee-keepers' Association was formed at Hanford, and possibly still exists. The Tulare County Bee-keepers' Association is about 17 years old; is well organized, and had two delegates present—Mr. Walker, of Tulare, its president, and Mr. Epperson, of Fresno. The Imperial country, in the southeastern part of the State, has an association, which, like the State association, is incorporated.

The writer was honored with the chairmanship of a committee dealing with organization and inspection. The former was reported substantially as follows:

All honey-producers in the State are requested to join the State association, which shall consist of northern, central, Imperial, southern, and any other divisions that may be formed. County clubs are to be formed in each division. For administrative purposes delegates are to be elected to each division from the county clubs, and to the State association from each division.

No law can be passed on inspection till next winter, and the committee's plan contemplated the above organization by that time. The main features of the plan are somewhat similar to the above in formation. The Governor of the State shall appoint a State board of apianian examiners whose members shall not exceed the division of the State association in number, from a list of names to be submitted by the State association, and the Governor shall remove the same for cause. The board shall appoint a State inspector and county inspectors, and shall be paid actual expenses and per-diem salary by the State. The State inspector shall have laboratory facilities with the University of California or elsewhere; shall give necessary assistance to county inspectors, and shall cause necessary inspection to be done by competent persons in counties where there are no inspectors, at expense of counties where inspection is done. County inspectors shall appoint deputies when necessary; may remove them, and shall be responsible for their acts. All the above shall be under bonds, excepting the deputies. County inspectors and deputies are to be paid by the county.

While the above is from memory, it is close to the report submitted, which was turned over to the executive committee. After due amendment we hope it will be endorsed by all the associations in California.

The delegates from the State association, Sec. A. B. Shafner, Los Angeles, and Inspector J. W. Ferree, of Surrey, as well as the Tulare association delegates, were of

much assistance, and worked untiringly for the general good.

The first day, State Entomologist Prof. C. W. Woodworth was up from Berkeley, and was frequently called on for advice. He said we should confer with the various societies of our industry for a law, take plenty of time to get it right, and then he would work for its passage. He has conducted a class in apiculture at the University for 17 years.

The last day, Dr. A. J. Cook, State Horticultural Commissioner, was with us for a while. To bee-keepers he will ever be "Prof. A. J. Cook." He spoke with much feeling of the older bee-keepers who have largely passed away, and assured us of the friendship of the bee-keepers at the south end of the State. He told us how Governor Johnson had lately called a special session of the legislature to manage an insect not as large as a house-fly. Twenty minutes after the legislature convened the desired measure became a law, and the legislature adjourned! He told us to prepare a good law and he would help us get it through. We enjoyed his talk immensely, even if he did "josh" us freely.

Our friends from the south told us that the State association reports its meetings to the papers, as it wants it done by a censor, and not as a reporter who knows nothing of our pursuit would do it. During the meeting the need of such a plan was glaringly apparent, and all bee-keepers' associations could well consider this point.

Mr. W. Gear, of Vorden, was elected secretary for the following year.

Ceres, Cal.

MOVING OVER 1000 MILES, AND SECURING 160 POUNDS PER COLONY.

BY B. F. SMITH, JR.

April 26 I received notice I was to be transferred from the Omaha to the Sheridan division of the C. B. & Q. R. R. The year 1910 was nearly a failure in our locality in Nebraska; but having fed my 23 colonies until each had 25 or more pounds of stores for outdoor wintering, I expected to find them in good shape for the trip. I found two dead and one with just a little bunch of bees with a drone-layer. This left just 20 with two doubtful ones, which I did not have time to examine.

About 2 P.M., with thermometer at 55, the covers were removed and wire cloth nailed on instead, thus leaving just a 3/8-inch space over frames. About 5 P.M. it was a little colder, and screens were tacked over the entrances, and the work of loading commenced. All household goods were loaded in one end of a 40-foot box car, and a rack or gallery built in the opposite end, upon which the covers, supers, and chaff-trays were loaded.

I had just enough one-inch boards to cover the bottom of the car in the end I intended for the bees, and on top of these I put

about a foot of straw, carefully smoothing out the bumps. The hives were loaded in four rows of five each, and held in place by 1x4 strips nailed to the sides of each hive with a straw bumper between end hives and car. The hive entrances were all toward the car door with about 3 feet between the top of the hives and the rack above. The rows extended nearly to the door; and between the doors I had five crates of chickens, a cot, chair, gasoline-stove, and water-barrel. As the last piece was loaded, the engine backed on to the car, and the start was made.

We had not reached the first station before I discovered that one pair of wheels on that car were not true, and at a certain speed every thing in the car danced in a fashion that made me sick. As it was on the opposite end from the bees I tried to hope it would be all right with them. About half the first night was spent in bracing the chicken-coops and putting packing in where I could to prevent chafing.

The trainmen on my old division handled my car in fine shape; but as soon as I was among strangers the way that car was hit, bumped, and jammed made me wish that some of those switchmen and engineers would have to ride over one division in a car like that.

There were eight divisions, and that meant eight switchings; and although the car was loaded by an expert loader, it had to be rebraced several times. The hives, however, did not move on their bed of straw.

Saturday morning we arrived at our destination in the Big Horn Basin, Wyoming, in the midst of a snow storm, and the bees remained in the car until Monday, making the total time just one week. I found the two doubtful colonies and the one weak one dead. The two had been queenless before loading, so that there were none but old bees. The smaller colony suffered because the frames slipped over. Some were Hoffman frames and some loose hanging; but only one of these moved. All the bees had been sprinkled four times daily except the two last days. Temperature ranged 50 to 75°.

The late storm destroyed all the fruit-bloom, and I commenced feeding May 15. On June 14 sweet clover started to yield; then alfalfa and wild licorice. The flow did not let up until frost, Sept. 20. All colonies were tiered up as high as I could lift the supers before any were removed. Three colonies were divided, but I had no swarms. In all, there was a crop of 3050 pounds of water-white extracted honey and 150 pounds of comb; and I had 20 colonies ready for winter.

During July I found a swarm in a rabbit-hole. It had evidently swarmed, as there was just a little sealed brood with several vacant queen-cells and a virgin queen. This colony I transferred to a hive, and it built up to six frames without assistance.

Cawley, Wyo.

[The usual plan is to locate the hives in the car so that the frames are parallel with

the rails, so that, when switching is going on, and the car is constantly being bumped, there is not so much danger of breakage. Your record, however, was very good.—ED.]

FENCES VERSUS SOLID SEPARATORS.

Narrow Versus Wide Cleats.

BY F. GREINER.

It is still vivid in my mind what trouble I experienced with the comb-honey supers which I used during the first few years of my bee-keeping in 1875 and thereafter; but I found something after a while that worked so well that even now I do not see the need of seeking for any thing better; and had I not been led to using no-beeway sections, which made it necessary to use either fences or cleated separators, I would have nothing more to say on that subject. When the no-beeway section was first brought out by Mr. Morton, a discussion arose as to how wide the vertical cleats should be, and it seems that one-fourth inch has been settled on, although at one time it appeared that three-fourths inch, or at least something much wider than the present regular width of one-fourth, would gain in favor; but of late, and for some years, our comb-honey producers have said nothing on the subject, which seems to be accepted as evidence that these narrow-cleated fences give the best of results and are satisfactory.

Now, it happened that, at the time I wanted to make my plain-section supers, fences could not be bought; none were offered for sale; and as the evidence seemed to be in favor of a wider cleat I made up my cleated separators with cleats three-fourths inch wide. Wishing to test fences also, I made up 25 sets of fences with narrow cleats one-fourth inch wide, as are commonly used now, except that the separator material was one-eighth inch thick instead of one-sixteenth, as the larger part of the fences in use are made. It also happened that, soon after this, I bought some 20 or 25 supers with fences of the narrow-cleat type. These supers of different styles have been in use ever since, which is quite a term of years, and now I desire to give my experience along this line.

I want to add that, a year ago, I wanted to increase my stock of supers; and, not wishing to spend much time in making up fences, which is a very laborious task when one has not machinery to do it with, I bought 500 Danzenbaker fences. All of these were used last season with the others. Now as to the result:

The smoothest honey has always been produced with the solid wood separator, whether cleated or not; i. e., whether it came out beeway or no beeway section-supers. There was always the least of what friend G. M. Doolittle called "mangled" honey with these solid separators.

The separators (or, rather, the fences of the 25 supers which were bought during the earlier time) were very flimsy; they were

only $\frac{1}{8}$ inch thick, and of very soft timber. My bees showed very little respect for them, and gnawed them in a frightful manner. They have long been out of commission, and the supers have been entirely remodelled to correspond with my regular stock. The resulting honey had always the washboard appearance, and many legs were attached to the faces and fences. There was another peculiarity of these supers; the combs in them ran crosswise of the frames in the brood-chambers, making it necessary to keep hives perfectly level both ways. This is, as every one knows, a very undesirable feature, and can not be tolerated except in house-aparies or tenement hives.

The honey produced with the Danzenbaker fences also lacked in smoothness when compared with that produced with solid separators. But the feature I wanted to draw especial attention to as being the result of the narrowness of the cleats is this: The sealing of the cells next to the wood is quite often so drawn out as to be slightly attached to the cleats; and when the filled sections are removed from the supers this sealing is somewhat broken, and a leak is the result. This may not be very serious, for bee-keepers seem to be passing it by without making objections, although few have mentioned the matter. A wider cleat entirely prevents this trouble, as is clearly shown by the honey produced in my 100 or more supers provided with such wide cleats. The fences with the narrow $\frac{1}{4}$ -inch cleats, which I made some fifteen or more years ago, have always given us the same trouble, more or less, just as the Danzenbaker fences did, but have stood the wear exceptionally well—probably because the material was good sound timber, and of good thickness. I doubt whether the thin Danzenbaker fences will endure like that. My suggestion would be to make thin separators or fences of hard wood—maple, elm, or something of that nature.

Before I forget it I want to say that we can get along with the "legs," or little attachments the bees are apt to build between the fences and the combs, much better than we can with the other nuisance mentioned, of having the sealings attached to the cleats. The legs are easily detached by running an eight-inch hack-saw blade through the beespaces where the attachments appear. Before unloading filled supers we stand them up on the bench so that the light will shine into the spaces; thus we readily see where there are any attachments. This past season we had some supers which looked very discouraging to us on account of the many legs. At first I thought I would not find a single suitable section in a whole case for shipment; but after sawing off the legs there was not a spoiled section to be found; while, had we omitted this, not a section in some of the worst cases would have been fit to ship. But we have no remedy to prevent mutilation when the sealings are attached to the cleats.

Naples, N. Y.

FOUNDATION SPLINTS.

How Made and How Used.

BY DR. C. C. MILLER.

M. C. Thompson, Milwaukee, Oregon, inquires about foundation splints. They are made by sawing and also by slicing. First the wood is cut into sheets $\frac{1}{8}$ of an inch in thickness. Then a number of sheets are laid together and cut into splints, making the splints $\frac{1}{8}$ of an inch square. A saw for the purpose must, of course, be very fine, and the slicing-machine is a large and powerful affair that I suppose is quite expensive. I have never made any splints, as I can buy them for 60 cents per thousand with an additional 10 cents for postage if sent by mail. I couldn't make them nor have them made locally for any such price. They would work all right if made long enough to reach from top to bottom-bar, but would be troublesome to put in, so they are made $\frac{1}{4}$ inch shorter than that. For a frame of Langstroth size, with top-bar $\frac{3}{8}$ thick and bottom-bar $\frac{1}{4}$ thick, that makes the splint $7\frac{1}{4}$ inches long.

Broomcorn might work for splints, only it would take a good deal of care in selecting, and at that would not be of such uniform thickness as the spliced splints. I hardly think you would make satisfactory work splitting wood into splints, even if your cedar and fir are very straight-grained. But you can easily try it.

Now the manner of putting in the splints. The foundation is fastened to top and bottom bars; then the frame is laid over a board such as is commonly in use, being made to fit rather loosely inside the frame with stops on the edges to allow the foundation to rest on the board. The splints are thrown into a square shallow tin pan that contains hot beeswax. They will froth up because of the moisture frying out of them. When the frothing ceases, and the splints are saturated with wax, then they are ready for use. With a pair of plyers a splint is lifted out of the wax (kept just hot enough over a stove), and placed upon the foundation so that the splint shall be perpendicular when the frame is hung in the hive. As fast as a splint is laid in place, an assistant immediately presses it down into the foundation with the wetted edge of a thin board.

I have used different makes of brood-foundation with splints, and of different weights—heavy, medium, and light. About $1\frac{1}{2}$ inches from each end-bar is placed a splint, and between these three other splints at equal distances, making five splints in the frame. This for heavy or medium foundation. For light foundation I have used seven splints to the frame.

I see no reason why the plan given by Mr. Atwater, in April *Review*, should not work all right.

If splints are given when the bees are not busy gathering nectar and building comb, they will be gnawed out. The thinner the foundation the more likely the gnawing.

Heads of Grain from Different Fields

How Often is it Necessary to Inspect Colonies for Foul Brood?

Dr. C. C. Miller:—How often would you recommend examining hives for foul brood, and at what season of the year? In April or May I examined a colony that acted strangely, and found about one-fifth of the unsealed brood dead and black. In three weeks all cells were cleaned out, and being filled with eggs and larvæ; but about a third of the worker-cells hatched out all drones. No more disease appeared. I pronounced it pickled brood. These bees were dark hybrids.

In August I killed the queen, which was a fine-looking one, and introduced a golden Italian one in her place. Soon beautiful bees began to hatch; but within ten days from the time they began to fly out, there would be from four to seven dead ones on the alighting-board. But there were no old nor hybrid bees among the dead ones. The unhatched brood was healthy. Why did the young bees that had never done field work die off? At present all seems to be well.

Gewda Springs, Kan., Dec. 9. D. W. HOLLAND.

[Dr. Miller replies:—]

Of course there's no use looking any time before brood is present in spring, nor, indeed, for some time after. Wait till colonies have built up into prosperous condition and are bringing in honey. From that time until brood-rearing ceases in the fall it will be well to make an inspection every two or three weeks if foul brood is in the apiary, either for treatment or to make sure that no treatment is needed.

You are likely right in attributing that 20 per cent of dead brood to the pickled-brood business, if we may call starved or chilled brood pickled brood. But the drones from worker-cells should be charged to a defective queen. The dead young Italians may likely be charged to the larvæ of the moth. These run their galleries along the surface of the sealed brood, mutilating the young bees, which are then thrown out.

C. C. MILLER.

When is the Best Time to Remove Old Crooked Combs?

Are Jumbo frames self-spacing?

What is the best way to remove old useless brood-comb from the hive so that there shall be as little waste as possible of honey, brood, and pollen?

I have no honey-extractor. Some of my colonies have contracted foul brood, and I find that it is those colonies that have old brood-combs.

Bainham, N. Z.

E. B. LANGFORD.

[The Jumbo frames are usually self-spacing of the Hoffman type.

If colonies require feeding in the fall, old crooked combs can be gotten rid of very easily at such a time by removing them before the feeding is done, and then contracting the size of the brood-chamber to accommodate the combs left which contain the winter stores.

Early in the spring a great many poor combs can be taken away; and a little later, when the bees begin to need more room, frames of foundation can be substituted.

During swarming time the old combs may be removed entirely, and the bees shaken on to full sheets of comb foundation. The old brood-combs are then stacked up, the young bees allowed to hatch, and then, after three weeks, these young bees shaken in front of various colonies in the yard that may need strengthening. The old combs are then empty and may be rendered up.—ED.]

Capping-melters Darken Amber Honeys.

I am one of the oldest bee-keepers in Australia, and for a long time the largest, although I do not think I am at present. I have had a bottling establishment in Sydney for a number of years; and as it was always necessary to use heat I had considerable experience of the effect of heat on different honeys. There are some honeys gathered in Australia of good consistency and flavor, and very light color, which a capping-melter would not injure much; but the majority of darker honeys it would damage to a great extent. There are some honeys here that will not stand heat at all; and if they candy it is better to let them go in that state than to attempt to liquefy them, as they get so

dark and rank. For that reason a capping-heater would be of no use to me, nor, I think, to the majority of Australian bee-keepers. If I used one I would certainly keep the honey apart and sell it on its merits. I would not allow it to run into the tank.

Mr. Beuhne is, I think, peculiarly situated, inasmuch as he has a location which gives him a very large field of light honey—the sort which receives the minimum amount of damage by the application of heat. Both here and on my other farms, 400 miles south, I get some honey which I could safely put through a capping-heater, but I get a lot which I could not.

Cappings are undoubtedly a nuisance—that is to say, the accumulations during extracting are; and the only merit a heater has, in my opinion, is to get them out of the way quickly; but if this is done at the expense of the quality of the honey the advantage is a doubtful one. I will tell you later on, if you care to know, how we manage with our cappings.

MAJOR SHALLARD.

South Woodburn, N. S. W., Australia.

[We are very glad to use what you have to say regarding capping-melters; and we should be pleased to have you continue the subject, and tell how you dispose of cappings.—ED.]

A Swarm that Issued when the Queens were Ready to Hatch.

One Sunday morning in July we noticed that a swarm had just gone out of one of our hives previous to our visit; and in order to make sure from which hive the swarm came we opened the one which, the previous day, seemed about to swarm. This happened to be the right hive; and on examining the frames we saw two or three queen-cells on which the caps were so loose from the young queens trying to free themselves that we had no trouble in removing the caps with our fingers and releasing the young queens, which immediately ran out on the frames. That was the first time in our experience that we had so good an opportunity to test this much-mooted question. We think this bears out your experience also, that the young queens hatch at or about the time the old queen goes out with the swarm.

Clamart, France, Nov. 21.

GEO. STEPHENS.

[There has been plenty of proof to show that the swarm occasionally issues about the time the cells hatch; but it seems likely that, in the majority of cases, it comes out about a week in advance. Unfavorable weather conditions probably account for the occasional delays.—ED.]

Will Honey Transmit European Foul Brood?

I wish to know if European foul brood might be transferred from place to place in the honey. I understand that it is fully admitted that the American type is. Will honey extracted from an apiary containing European foul brood, and shipped to another State, and fed to bees, bring on disease?

Kerman, Cal., Dec. 13.

CHAS. A. LEE.

[This letter was referred to Dr. E. F. Phillips, who replies:—]

The question raised is, of course, important; but I know of no way to answer it definitely. The cause of European foul brood is not known, and therefore we would not know what to look for in the honey. Furthermore, even for American foul brood (which we know is carried in honey) it is difficult to find the organisms. Some practical experiences would certainly indicate that European foul brood is carried in honey; but, on the other hand, the success which is sometimes experienced with the dequeening method of treatment makes this somewhat questionable. Every phase of this disease is a puzzle, and one who can speak definitely of it usually does not know. E. F. PHILLIPS.

In Charge of Apiculture.

Bees Returned to Old Location when Set out for a Midwinter Flight.

The mercury rose to 66 degrees, so I ventured to set my bees out for a flight, and they flew freely all day. I set them on the opposite side of the house, and some of the bees hung around the old stands, but returned all right. That shows their memory.

Derby, Vt., Dec. 12.

W. H. WILSON.

Italians are Gentler and Produce More Honey, but they Also Swarm Worse.

For some years I have had a yard of black bees about three miles from home, while at home I have only Italians; and I have endeavored in every way to arrive at the truth in the matter as to which is really the better under all ordinary conditions. At first I thought the Italians were the better; then one season caused me to change my opinion, and I have now come to the conclusion that I prefer Italians; but I think there is really but a very little difference as to the amount of honey gathered by each race. While the Italians have proven to be a little ahead in the amount of honey gathered, they have overbalanced this by being worse to swarm, especially early in the spring, before there is any honey of notice to gather.

Another difference that I have never seen mentioned is that the blacks are not nearly as apt to use up their stores by rearing brood early and late in the season. I have rarely found a black colony starving in the winter or spring, while this is almost the rule with Italians here, as they nearly always require more or less feeding, either in the fall or spring.

On the score of gentleness the Italians are far ahead of the blacks, as the latter will sting much worse, and are so nervous that they will fall from the combs to the ground, where they will scramble about and crawl under one's clothes if possible. I am pretty sure that the Italians slightly excel as honey-gatherers, and very much so as to gentleness and ease with which they may be handled. Taking every thing into consideration I now prefer Italians; but it is a great deal more trouble to keep them pure, as there are always some blacks in the neighborhood, either in trees in the woods or in hives. I find that this is to some extent the case in most of the country, as a great many queen-breeders send out queens that produce hybrids which are as cross as cross can be. I have had hives of hybrids that were so cross that an inexperienced person would have been in danger if he had tried to handle them.

Stonecoal, W. Va., Dec. 1.

W. C. MOLLETT.

Mouse-proof Entrance.

During cold weather there is often great damage done by field mice where the hives are left on the summer stands and the entrances left unprotected; but if a wire mouse-screen, like the sample I am sending you, is used, there will be no trouble at all

from mice, and the bees can pass out and in freely when the weather is warm enough for them to fly. I first bevel the entrance as shown, and I find that the bees pass in and out with much greater facility than with the ordinary entrance.

Wilkesburg, Pa.

W. D. KEYES.

Bees Uneasy Because of Low Temperature in the Cellar.

Why are my bees restless in the cellar with the temperature down to 32°, and the air good? They keep up a constant buzzing, and a few come out and die.

Glenwood City, Wis., Jan. 12.

J. E. COOK.

[The trouble with your bees is undoubtedly because the temperature of the cellar is too low. It should seldom go below 45° F.; and when it goes below 40 the bees are apt to roar or show that they

are uneasy. Dr. C. C. Miller, in one of his articles some time ago, described how he quieted his bees by raising the temperature.]

This roaring may be caused by bad air, even though the temperature be right; or it may be caused by too low a temperature, even in good air. It may be advisable for you to put artificial heat in your cellar. The best way, of course, is to put a small drum stove, burning hard coal, or something that will give a steady heat, down in the cellar, connecting the same to a chimney reaching down through the floor. Of course, if you can not apply this kind of stove you might use a large coal-oil lamp; but this makes the air of the cellar very foul. When the temperature of the cellar is as low as 32°, and you have no means of raising it, your bees will be almost sure to die before spring.—ED.]

Association of Apiary Inspectors of the United States and Canada.

On Dec. 30, 1911, in Washington, D. C., there was formed a temporary organization of the above name with a view to increasing the efficiency of apiary inspection and to bring about a greater uniformity in the laws, and more active coöperation between the various inspectors.

A committee on permanent organization was formed, to report at a meeting to be held in Cleveland, O., in December, 1912, in connection with the meeting of the Association of Economic Entomologists. Prof. Wilmon Newell, College Station, Texas, is chairman of this committee.

A standing committee was also appointed on legislation for the purpose of drawing up a law incorporating the necessary and desirable features. The undersigned was appointed chairman of this committee.

All apiary inspectors and official entomologists of the United States and Canada who are interested in the advancement of apiculture are invited and urged to join in this movement for an increased efficiency in the fight against brood diseases. For the present it was decided to levy an assessment of \$1.00 per year on each member to defray necessary expenses. It is hoped that arrangements may later be perfected for affiliation with the Association of Economic Entomologists. Requests for membership and the assessment may be sent to the undersigned.

E. F. PHILLIPS,

Bureau of Entomology, Washington, D. C.,
Secretary.

DR. BURTON N. GATES, Amherst, Mass.,
Chairman.

Cellar Wintering Best when Bees can Not Fly for Over Five Months.

On page 741, Dec. 15, I note your statement, "It takes much less skill and time to winter bees outdoors," and "The average beginner will succeed better by it." I would take exception to both of those statements, especially for a man who lives as far north as I do, and in as cold a climate. Last winter my bees were without a flight for 5 months and 17 days; nor was there one day when they could have had a flight even if they had been outdoors. I lost 6 colonies out of 86.

Last year my bees had their last flight October 18, and there has not been a day since when they could have flown. I put them in the cellar Nov. 3.

We had one night in November when the mercury was 28 below zero. There have been several nights when the temperature has been to zero. The night of Jan. 1 the temperature was 35° below zero; Jan. 2, 26 below; to-night, Jan. 3, it is 24 below; and at no time in the last three days has it been warmer than 14 below zero. I think I had better stick to cellar wintering.

Robbins, Wis.

G. C. CHASE.

Clipping does Not Impair the Usefulness of a Queen.

Clipping queens, in my experience of over twenty-five years, does not usually in any way impair their usefulness or shorten their lives—at least they often live three or four years after being clipped—p. 523, Sept. 1. I usually cut square across all the wings, taking off about half of each.

If you want to kill bumble-bees or yellow-jackets, put some gasoline in a spring-bottom oil-can and squirt it into the nests. Do it before you stir them up. Bumble-bees can be handled by using smoke.

Payson, Ill., Dec. 29.

DANIEL E. ROBBINS.

Watering Bees in a Cellar.

I noticed in March, last year, my bees began to raise brood, in consequence of which they became very restless, after which I gave each colony a little saucer of water, which seemed to satisfy them. Is this the right thing to do?

Omaha, Neb., Jan. 5.

H. C. COOK.

[Water has been given the bees while in the cellar by some bee-keepers, and in a few cases it has seemed to quiet them. Whether it is because they needed the water for brood-rearing or what, we can not say. A good deal will depend upon local conditions. If water does encourage bees to rear brood, we would say that we would question the advisability of giving it to them in the cellar, because brood-rearing too early in the spring would be a disadvantage. The bees would be uneasy, rouse up, and make the colony too warm, and render it difficult to control the conditions properly.—ED.]

A Diagonal Line of Drone-cells.

A colony of bees superseded its queen in July. Several of the virgins being of good stock they were secured. They started laying Aug. 17. Two, that proved to be purely mated, were saved. These queens are somewhat slender in body, but apparently prolific. The brood is compact and regular, with the exception that drone brood is placed in worker-cells running in almost perfect lines of single cells diagonally across the comb. Some drone comb in the supers, to which these queens had access, was neglected. About the time the drones reared in the worker-cells matured they were cast out. During August and September two successive lots of drones were reared that way. Each lot consisted of about 100 such drones. I am a beginner; and, with the exception of some little drone brood appearing in worker-cells in the early spring, I have not experienced this condition. What do you think of these queens?

Philadelphia, Pa., Jan. 13.

E. ROHNER.

[Perhaps these particular combs that contained drone brood had sagged so that a line of cells was stretched large enough so the queen laid drone eggs in them. It is hard to conceive of only one line of cells being stretched in this way; but this is the only explanation we can think of. If these combs are wired diagonally this might have something to do with the matter. You had better watch those queens next season.—ED.]

Greasy Waste Dangerous.

I note what you have to say concerning the footnote to my comments on cotton as smoker fuel, p. 664, Nov. 1. Greasy waste is nasty to handle. Reload the smoker and then handle some snowy sections of honey. It is dangerous to leave about. Its tendency to spontaneous combustion is great, particularly when it contains certain oils and greases, and the smoke from it stinks. There are plenty of better things. Plain cotton, in waste rags, or yarn, always makes trouble for me when used as smoker fuel. Mr. Latham is very emphatic in its condemnation. Repeated use of tobacco, say on several consecutive days, often causes trouble.

Providence, R. I.

ARTHUR C. MILLER.

[If a little care is used as to the place where the waste is kept, there is no danger of a fire. The great advantage of this fuel over any other that we have tried is that it lights at the touch of a match, does not make a hot fire, and never goes out until it is all used up.—ED.]

Meeting of the Ventura County Club.

At a meeting of the Ventura County Bee-keepers' Club, held at Fillmore, Cal., January 6, 1912, it was unanimously voted to join in a body the California State Bee-keepers' Association. Inspector Allen was upheld in the matter of quarantining all bees and queens from outside the county, on account of brood diseases. All queens and bees shipped into Ventura Co. must bear an inspector's certificate or they will be destroyed when they arrive.

Santa Paula, Cal.

E. F. McDONALD, Sec.

"Grandma" Wilson a Honey Salesman.

I wonder whether Dr. Miller realized what a fine salesman he had when he started that fine old lady on the road, page 659, Nov. 1. I have no means of knowing just how much she has benefited other bee-keepers, but I know she has sold quite a few

pounds of honey for me. If bee-keepers did but know it, right here is the secret of successful advertising. Let those with large healthy families or healthy old folks who consume honey regularly have photos taken, and have them published in their local papers, and they will often be copied widely. These articles are always interesting. I clipped the inclosed from the *Philadelphia Record*, East Stroudsburg, Pa. GEORGE H. BEDFORD.

[The clipping sent was a copy of the article as it appeared in GLEANINGS, picture and all. Yes, such items do good.—ED.]

Camphor in the Carbolic-cloth Solution.

Carbolic cloths can not be surpassed by any kind of smoker. I have handled blacks and hybrids, of very vicious temper, with the greatest of ease, and under many adverse conditions, as well as Italians. I procure a 4-oz. medicine-bottle and get 1 oz. of pure carbolic acid, also 2 oz. of camphor. Get a pestle and mortar and break the camphor up fine, then pour on the carbolic; and after it has dissolved the camphor, bottle for use. The reason I mention a 4-oz. bottle is that I have always found it handy in my pocket when out.

Toronto, Ont.

R. V. KEYHOLE.

How Many Kinds of Italian Bees are there?

What kind of Italian bee is the best? How far would it do to ship colonies of bees? I should like to buy some this spring. A. T. DANIELSON.

[There are but two main divisions or kinds of Italian bees—the leather-colored (often called the three-banded) and the five-banded. The latter bees have been bred especially for the color, and sometimes are more irritable and less hardy than the former. The red-clover Italians are simply one strain of the ordinary leather-colored.

Bees may be shipped almost any distance. By express it is possible to ship across the country; and if the bees are prepared in good shape they should go through all right.—ED.]

No More Bees Shipped into Imperial Co., California.

At a meeting of the Board of Supervisors of this county an ordinance was passed for the protection of the bee industry of this county. This goes into effect Feb. 1, 1912. On and after that date no more bees will be permitted to be brought into this county. This act became necessary because so many bees were being brought in from infected counties. This county contains about 11,000 colonies of bees; and with prospects of a poor season in coast counties there was danger of importing brood diseases. Any violation of this ordinance is punishable by fine or imprisonment, or both.

A. F. WAGNER.

Inspector of Apiaries of Imperial Co., Cal.
El Centro, Cal., Jan. 15.

Clusters Hanging Clear to the Bottom-board in a Temperature of 19° below Zero.

I am afraid that a good many bees have "gone the route." One man I know, who will not spend a dollar for a bee-journal, lost eight stands of bees early in the fall. They all starved to death.

I winter my colonies on their summer stands. They are still all right. The clusters are hanging clear to the bottom-board. Yesterday morning it was 19 degrees below zero.

Plattsmouth, Neb., Jan. 8.

J. NIELSON.

Why did the Bees Destroy their Own Queen-cell Cups?

I had a colony last spring. While I was looking through it I found five queen-cell cups partially built, and just laid in by the queen. About a week later I went with a new hive, with the intention of dividing, but there was not a cell to be found. I wonder what had become of those cups or partly built cells.

Filer, Idaho.

LOUIS A. BARBEZAT.

[Is it not probable that a swarm had issued meanwhile?—ED.]

Something Needed to Kill the Grass.

What the bee-men want in this part of the country is some way to kill out the grass and weeds among the hives so that the mountain or brush fires will not destroy whole apiaries as they have done this year.

San Marcos, Cal., Jan. 9.

G. F. MERRIAM.

Our Homes

A. I. ROOT

Wist ye not that I must be about my Father's business?—LUKE 2:49.

Rejoice and be glad, O daughter of Edom.—LAM-ENTATIONS 4:21.

Rejoice in that day, and leap for joy.—LUKE 6:23.

I have several times remarked that my chickens at times talk by actions almost as plainly as words, or sometimes even plainer; but it was a lesson and a revelation when, a few days ago, a dog not only talked to me but he preached to me a most wonderful sermon—the sermon I am going to try to give you this beautiful morning on the second day of the new year. I have read many wonderful stories of canine sagacity, but many of them I did not believe; and I am frank to say that, had I not seen it with my own eyes, I fear I should be loath to credit what I am going to tell you.

I was sitting at my typewriter, as I am now, when a strange dog came trotting up the cement walk. Supposing him to be a tramp dog that was probably hungry, and that would likely hang around if we fed him, I was about to drive him away as gently as I could, for he seemed after all to be a nice-looking dog. I went toward the screen door just as he came up opposite on the outside. Before I opened my mouth to speak, however, I paused, because of his bright look of intelligence. He was a beautiful shepherd dog, and his appealing look at once attracted my sympathy as well as curiosity. As soon as he saw he had my attention, he turned partly around and looked toward the gate and then again at me. Following his look I was startled to find one cow partly through the open gate, and another inside greedily grabbing the luxuriant bright-green Bermuda grass. When he saw I had taken in the condition of things he made a quick jump toward the cows and gate, then turned back as if waiting permission from me to drive the cows back. Of course I said at once, "You are a real good doggie, and I shall be very glad to have you drive them out; and I am everlastingly obliged to you for having so kindly taken an interest in my property and my premises."

Now listen while I tell you how he managed it. He could not do any thing with the cow that was rapidly getting further and further into the yard until he first got the other cow out of the gateway, where she seemed bound to "hold the fort." Accordingly he first tackled her, and with much skill and good judgment crowded her back, clear out of the way. Then he went for the other cow, kept her out of the shrubbery, and, after he had driven her safely outside, came up to me for a word of praise for doing so skillfully what very much needed to be done. After I had given him a good patting on the head, and called him repeatedly "good doggie," he hurried off through the

gate and was off, as if he felt he had, perhaps, delayed some important errand.

A few days later, while a drove of town cows were passing he came in again to give us warning. The gate was again unhooked, and was open a little way. This time Mrs. Root was present, and she said the dog should be rewarded for repeatedly rebuking us for our own carelessness. But he was bounding off again just as she succeeded in throwing a piece a biscuit toward him. At first he acted as if he had not time to come back and get it; but finally deciding it would hardly be courtesy to a lady he came back, picked it up, and started on again. He did not stop to eat it, but kept it in his mouth; and when she threw him a second piece he looked at it a minute, and then seemed to decide he must not waste any more time, and was off with big bounds. At present writing I have not been able to decide who is the owner of this remarkable dog that seems to be looking after the affairs of mankind in general.

At the risk of having some of you think me irreverent, I am going to confess that this dog made me think of the first of our texts to-day; but I would put it this way: When he decided he could not stop to come back for the second piece of bread, he had in his sagacious mind "Wist ye not I must be about my *master's* business?"

Well, the above is, at least to me, surprising; but it is not all of "my dog story." Some time afterward I stopped to leave a package at the express office up town. As I had to go to the grocery, the bank, the drugstore, postoffice, and other errands, my mind was busy for fear I should forget something. By the way, let me tell you I am getting bravely over my forgetfulness. I can now attend to half a dozen errands or more, and not forget any of them. Wonderful, isn't it? Now listen: Ever since I commenced going without a regular supper, and eating only apples, my memory has been constantly improving. In other words, I was losing my memory and getting old prematurely just because of eating *three* meals a day when *two* were a great plenty.

Well, on that morning, when I was rushing out of the express office because I had left my auto-engine running, a strange dog kept getting in my way. He danced up and down, ran before and behind me, and nearly jumped over my head while he gave voice to sharp quick barks of joy and animation—bow, *wow*, wow! Just as I began to say to myself, "Why, what makes that dog act so strange?" I took a good look at him, and, behold, it was my shepherd-dog friend. He was appealing and pleading for just one word of recognition and a pat on the head, and to be called "good doggie" once more from some one he had in past time served.

Do you see the point of this *dog* sermon? Now, when I had stopped to talk with him

and assure him I had *not* forgotten my faithful and devoted friend, his joy and gladness seemed to know no bounds. His joyous attitude over just a little kind recognition has been a rebuke to me ever since. And, by the way, is there anywhere else in the round of the whole animated creation such an exemplification of the text as a happy dog? "Rejoice and be glad." Had not a lot of us (we who are professing Christians, for instance) better take a pattern after a well-fed and well-trained dog? Are there not others than dogs who are literally hungry for a word of recognition, sympathy, or encouragement? perhaps some have done you important service in times past, and you have been so busy you have forgotten all about it.

This dog might have said truthfully to the bystanders who wondered to see the dog single me out from all the rest, "Why, Mr. Root and I both belong to the same church, and our delight is to serve all humanity wherever our services may most be needed."

Once more, are we rejoicing and being glad as we might be and ought to be? Have we not just as good a right to be glad as our canine friends? and have we not as much reason to be glad *every day* of our lives?

Belonging to the same church reminds me of an incident of years ago. A profane and drinking man was in the habit of swearing and blaspheming on the streets when a little under the influence of drink, and in this way he would often collect quite a crowd just to hear him swear. As nobody seemed to want to interfere (for he was a tough character), he seemed to be getting worse; and one day I decided I would try to stop him; and if I failed I intended to appeal to the authorities. I came up behind his back, and the crowd began to snicker as they looked toward where I stood, expecting, doubtless, to see more fun. He finally turned and faced me, and stopped entirely in his harangue. Some one said, "Why, Dave, what made you stop all at once when you saw Mr. Root was in the crowd?"

"Why, boys, I stopped because brother Root and I both belong to the same church."

The idea that the speaker ever belonged to *any* church, or *could* belong to any church, caused an uproar of merriment; and, if I recall correctly, I pushed forward and took his hand and called on all present to witness that David had confessed before the crowd that he belonged to the church of Jesus Christ. He was sober enough so he remembered what he had said, and it paved the way for several talks with him, the outcome of which was that he promised to stop drinking and swearing, for a time at least, and promised me he would come to me and give me notice *before* he drank another drop. For a year or more he was a sober man, saved his money, and cared for his family; and people began to hope he was a changed man for good. Finally he came to me, reminding me he had kept his promise so far, but, for certain reasons, he had decided to go back, partly, to his old habits. I reasoned, begged, and implored, but to no

avail. I finally urged the needs of his family. Said I, "Mr. H., you have more money now than you used to have?"

"Yes," admitted he, as he took out of his pocket a great handful of silver, "I have a little more money; but on the whole I think I will try a little drink for a while."

I did not know then, but I found out later, that during his hard drinking he had incurred a disease that is not easily managed, and Satan had put it into the head of this poor lost soul, ruined both in mind and body, that his forced abstinence was what made him feel so badly, and that a little drink *occasionally* would bring back his old former self. Poor deluded man! the drink only aggravated the trouble; and not long after, when I met him on the street his former jovial manner was all gone, and he told me he was near to death's door. He had scraped up a little money from friends, and was going *alone* to the city to see if any of the great doctors could give him any help. My conscience troubles me now to think that, if I had given a little more encouragement when he had done so well (like the shepherd dog), he might have tided over Satan's temptation, lived for years, and died a Christian after all. "Be ye not weary in well doing, for in due time ye shall reap if ye faint not."

PUMPKIN PIE AS AN ARTICLE OF DIET,
FROM AS HIGH AN AUTHORITY AS
DR. H. W. WILEY.

Our readers may recall that I questioned whether pumpkin pie is, as a rule, to be recommended as an article of diet. Well, our good friend Neal submitted the matter to Dr. Wiley, our United States Chemist. Below is what friend Neal says, and under it is the letter from Dr. Wiley.

In GLEANINGS for Aug. 1, 1910, A. I. Root throws mud at my eating pumpkin pies. Now, he can throw mud at my eating pumpkin pies, all he wants to, and it will be all right. However, the doctors claim that fat meat or lard is easy to digest, something like apples. Fat meat is an injury when burnt; however, as the lard content of pumpkin pies is doubtless what Mr. A. I. Root objects to, I think pumpkin pies should be all right. I have Dr. Wiley's opinion on the matter. I hope you may publish his letter, as I know of no better aid to eating lots of honey than squash or pumpkin pies.
Jonesboro, Ind. C. A. NEAL.

Mr. C. A. Neal:—I have your letter of the 3d instant in relation to the wholesomeness of pumpkin pie, and your reference to the opinion of Mr. Root that it is unwholesome. I am not competent to decide opinions of this kind respecting the wholesomeness and unwholesomeness, as a great deal depends on the individual. Foods that are often well relished and well digested by some persons will be rejected and regarded as injurious by others. Personally I am very fond of pumpkin pie, and have eaten a great many in my time, and hope I shall live to eat a great many more.
Washington, D. C. H. W. WILEY.

SOY BEANS IN OHIO.

I notice you mention soy beans in GLEANINGS. I have been growing them for three years. This year I thrashed about 100 bushels from 3½ acres. I think I have a very fine strain of medium green. If they are as valuable as you claim, I can raise many pounds of "beef scraps" to the acre. I like the coffee made from the early varieties.
Baltic, O., Oct. 21. JACOB MCQUEEN.

OPIMUM, MORPHINE, COCAINE, ETC.; A WARNING.

I have been a reader of GLEANINGS for about twenty years, and I do not remember seeing in A. I. Root's department any warning in regard to the use of powerful drugs such as opium and its products (morphine being the most common), chloral, and cocaine. As the use of such comforting drugs has grown to great proportions, both by evil persons and also by well-to-do and well-meaning persons who do not exercise enough care, I thought a little warning and perhaps help to some who have come under their binding power would be good.

The subject has been brought to my mind again strongly, because a very good woman of a little over fifty has just been taken to an asylum because of insanity caused by the use of morphine given by her husband who is a doctor; another is much used up by the excessive use of a nerve medicine which included chloral given by her doctor. She was taking six different kinds in two doses. I happened to see the prescriptions. Another whom I know has spent a whole farm for help since the doctor caused her to get the morphine habit. The doctor has the farm and she has the habit.

I am fifty years old, and took opium (in the form of laudanum) fifteen years. I took it for chronic looseness of the bowels. I was careful not to use much, and thought I would not acquire the habit; but after years of use I found I was almost a complete wreck. I could not digest any thing but two tablespoonfuls of the very mildest food, and could not sit up. My doctor was not to blame for my commencing, but said I could not stop. Finally, when I was so weak, we consulted another doctor. He said, "Take five drops less; then in five days take five less again, and so on till you are down to none." I took about sixty drops at two o'clock at night, and there was about two drops in a teaspoonful of nerve tonic that the doctor made for me. It was hard work cutting it down, but it could be done, and was done, and it is ten years now since I did it. I am not over the effects yet, but can now eat any thing in moderation; bowels are in perfect condition.

Opium is a terrible master. Don't take it. Use other means. I could have done without it and saved myself a lot of terrible suffering. And don't permit any doctor to give you cocaine. It is far worse than opium, and it is, as I said, a terrible master. One of the brightest and most skillful dentists we had in Pottstown became addicted to its use, and died in the very prime of life, unable to free himself of it.

I think coffee and the medicines having caffeine in them prepare the nerves for neuralgia. That is my plague now, and I think it is a result of migraine tablets for the relief of headache. Water has been a great help, drinking it night and day.

Pottstown, Pa.

W. W. KULP.

I heartily endorse all friend Kulp says in the above. In fact, I mentioned some time ago an experience with morphine, taken in a "cholera cure" medicine for chronic dysentery. Since using nothing but apples for my supper I have been entirely free from all troubles with digestion.—A. I. R.

THE WONDERBERRY UP TO DATE.

When the *Rural New-Yorker* made such a stir about offering the wonderberry as a "new creation," some scientific man, either in Washington or over in England, decided quite positively that it would be likely to send out sports that would produce poisonous berries. In reply to this, some of the defenders of the berries made fun of this assertion. The following clipping from the *Detroit Free Press*, sent us by one of our subscribers, would seem to show that it was not such a joking matter after all:

"WONDERBERRIES" MAY CAUSE DEATH; THREE MYSTERIOUS CASES OF POISONING AT LEONIDAS ATTRIBUTED TO FRUIT.

Mr. and Mrs. Michael Stealman, of Leonidas, are in a critical condition from eating "wonderber-

ries" from a bush owned by William Merritt, of that village, who recently died under mysterious circumstances.

The old couple, both nearly 70, ate the berries furnished by a neighbor, and this morning both were found unconscious on their bedroom floor, where they had lain all night. They are still in a state of coma, and not likely to recover.

It is now believed that Merritt, who died while on his way to a Marshall doctor to have his case diagnosed, died from the same cause.

Battle Creek, Mich., August 16.

THE "WONDERFUL DISCOVERY."

Mr. A. I. Root:—"Another wonderful discovery in the chicken business," in Oct. 15th GLEANINGS, interests me. I like to read your poultry department, and value it more than any poultry paper I take, although I do not take much stock in some of your wonderful discoveries. "There is more in the feed than in the breed of the hog." I find that, when I forget to feed my hens at night, the egg-basket is not so full the next night; also when I change from soft mash to dry feed there will be a falling-off in eggs. My hens are moulting now; and the same hens that laid nearly every day a few weeks ago are now laying one or two eggs a week. I have learned a few things. One is, you can not make a hen lay if she does not want to; another is, there is no use in trying to make a chicken live when it wants to die.

Factoryville, Pa., Oct. 25.

EARL SEAMANS.

"FORECASTING" THE LAYERS; TWO EGGS IN ONE DAY, ETC.

Mr. A. I. Root:—The following is an egg-laying report:

Last winter our one pen of 24 Silver Comb White Leghorn pullets started laying during November. I trap-nested them during the months of December, January, February, March, and April, so as to be able to hatch eggs from our best layers during the spring. I found no regularity as to their laying; in fact, one pullet laid two eggs in one day on two different days (that is, four eggs in two days), and another pullet laid two eggs in one day. Our hens were well fed, well housed, and well taken care of. They averaged, for the months mentioned, 19.5 eggs per bird per month.

Red Wing, Minn., Nov. 13.

E. A. LINDELL.

HENS THAT LAY TWO EGGS IN ONE DAY.

I have known hens that lay two eggs in one day—that is, one very early in the morning and another late in the afternoon, then another the next day about noon.

I have had Indian Runner ducks several years. They are great frog-eaters, and great layers in the spring and summer; but they do not lay in the fall or winter. Mine make nests in the brush about my pond, or near it. At one time one made a nest and hatched some ducks under a hive of bees. I find that these ducks very rarely drop eggs promiscuously, for they practically always lay eggs in a nest.

Carlton, Colo.

JAS. H. WING.

Kind Words From Our Customers.

OUT OF DARKNESS AND INTO THE LIGHT.

Mr. Root:—I wish I could meet you once, for you have saved me from a drunkard's life and from many other bad things. You have also taught me a lot about poultry, gardening, and health; and I have thanked the Lord, too, that I have learned to do right. I also thank you very much for writing so many good things in GLEANINGS. I will let you know of my experience, and how you helped me to be a different man in life.

This spring I was married to a nice bright farmer girl, 19 years old, I am 23. I took your advice to get married and start young. Of course it cost me something, for I am doing big farming; but with the help of the Lord I shall get out of debt. Then I am going to work to find a little place of my own, so I can raise fruit and poultry. I have a few colonies of bees for health and pleasure, besides running a 160-acre farm. I read many farm and poul-

try journals, also the Bible, and they all do me good. I also read T. B. Terry's health book.

The farmers here are mostly Germans. They drink, smoke, and chew tobacco. I soon fell into the same habits. I was getting to be a real drunkard. I also got drunk sometimes, and received some hard knocks. I did not care what I did. I also smoked and chewed, but still supported my good mother, for that is one thing I did not neglect. I never was a very strong boy, so my health was beginning to fail. But it was just then that I commenced reading GLEANINGS and your health notes. I soon found that fresh air is the best thing for me to sleep in at night, as I had a kind of lung fever. I also read your temperance talks, and found out that hard drink was the cause of my poor health. I was also having some sad experience in the way of drinking, so I thought I would put a stop to it, and I did so. I soon found, after leaving whisky alone, that my health was improving, and now I am as well as any young man, and I am living happy with my young wife, whom I soon fell in love with after I let drink and other bad practices alone. The experience I had with drink was this: Whenever I went to help my neighbors shell corn, thrash, or do other things, they would give me all the drink I wanted, and thus many of us got drunk. When night came I would go home weak and sick. I always thought the work tired me out; but it was the drink. I can now go home as fresh as I started, after a hard day's work at my neighbors'; and there are many others who are learning from me now. You don't know how much I thank you for your good talks in GLEANINGS.

Elk Creek, Neb., Nov. 2.

E. C. ULRICH.

[May the Lord be praised, friend U., for the good news you tell us in your kind letter. What you say about your good wife reminds me of a beautiful book that is almost worth its weight in gold. The title is, "Fell in Love with his Wife." It was written by E. P. Roe. Mrs. Root and I read it years ago, and we have both very much enjoyed reading it again. You can get it of Sears, Roebuck & Co., Chicago, for 33 cents. God grant that you may continue to "fall in love" with the dear woman more and more every year that God permits you to live together.—A. I. R.]

HOW A MAN WITH ELEVEN CHILDREN "MADE GOOD."

I like GLEANINGS very much, and I thank God for your fearless denunciation of evil, and your kindly advice to the erring.

I am much interested in W. S. Cohenour's letter, p. 639, Oct. 15, as it sets forth the condition I was in myself, twelve years ago. With a large family to support, and keen competition in my trade, it was like making two bites of a cherry. This was in old Ontario, so we gathered our little all and moved to this land of promise, New Ontario, Thunder Bay District, 15 miles from Port William. On arriving here 12 years ago, the 20th of Oct., 1899, I had only \$18.00 left to face a winter and buy food and clothing for a family of eight, besides buying all feed for four horses and nine head of cattle for two winters. The only milk cow among these died in the spring, and my finest horse died the following fall. I gave another horse away for lack of feed, so was left with a very unevenly matched team (a heavy mare and a two-year-old bronco). We settled on an absolutely wild farm. Now for results: There have been five added to our family. The eldest is now a qualified grain inspector, holding a steady position, with a home of his own, paid for, in the city. The next three are schoolteachers with salaries ranging from \$450 to \$525; the rest are smaller, but all aiming in the same direction. We have 80 acres under cultivation, farms well fenced, good buildings, barn 40 x 100 feet, house 20 x 28, with kitchen 12 x 34; cement cellar and cement walks; rural telephone in the house, communication with neighbors and the twin cities (Port William and Port Arthur). I have laid out over \$1400 in vehicles and implements. My farm stock has not diminished, and yesterday I put in the cellar 84 colonies of bees. I was 39 years of age when we came up here. We all rolled up our sleeves and went at it—I at my trade (plastering), and my good wife, boys, and girls doing their best on the farm at home.

Now, if I were an American, as Mr. Cohenour, instead of soliciting charity from the millionaires I would strike Mr. Roosevelt for a bonus for the fine large family.

I hope to see this man succeed, as I see that he says as I do, "Owe no man any thing."

As poultry seems to be what he aims at, I might quote prices here. From 25 cts. in spring and early summer to 60 cts. in winter. The demand for fresh eggs far exceeds the supply.

State River, New Ont., Can. JAS. M. MUNRO.

IS 75, BUT NO BEER NOR TOBACCO.

In reply to yours of Sept. 11, 1911, I would say that I have been a subscriber to your paper for many years—nearly twenty, I think. I have owned bees for sixty years with the exception of two years while in Nebraska. I value GLEANINGS highly, and don't know that I have any suggestions to make, realizing that it is managed by men who know a great deal more about the bee business than I do; and when I tell you that I am in my seventy-fifth year, and never drank a glass of beer nor a glass of alcoholic liquor except once (and that during a terrible pain in sickness), and never drew a whiff on a pipe or cigar, and never put any tobacco in my mouth, you can imagine how highly I value A. I. Root's Home talks and the stand he takes on temperance.

I am pretty much discouraged in the bee business. For three years in succession I have had hundreds of pounds of honey-dew, and have lost most of my bees from it during the winter. I don't like to sell the black stuff; and whether it is a secretion or an excretion I don't want to eat it.

Athol, Mass., Oct. 23.

A. M. V. HAGER.

"FORECASTING" LENGTH OF LIFE BY ONE 89 YEARS OLD.

I have been reading GLEANINGS for a long time. Some years ago, when you were teaching how to live to be one hundred years old, you said all who wanted to go along should "fall into the procession." I said, "All right, I will go with you, not for a hundred, but for ninety." I shall be 89 the 17th of November. I am well and hearty for my age. I ride over my farm on horseback. I go to town, three miles, in my buggy, every few days. I superintend all my affairs. I keep busy—so busy that disease can hardly get in.

Now, you may ask, how I do live. I aim to live moderately—not excessive in any thing. Moderation is the word I keep before me. I eat a little of almost every thing placed before me; but I eat moderately. I eat a little meat when I get hungry for it, but I often do without it for a week or more at a time. A boiled egg, a glass of milk, stewed fruit, apples mainly, and a biscuit make up my daily meals.

Tell me the manner of a man's life and I can reckon pretty close to the length of it. The manner of life and the length of it keep pretty close together. The young, many of them, go down from 18 to 30; others from 30 to 60, when, by a proper manner of living, they could reach the allotted threescore and ten. I think I shall reach 90, although a little feeble, and I hope you may go there and beyond.

Your Home papers are doing good. Keep them going for the uplift of our people. This is a long letter for an old man; but I wanted to say what I have, and more.

Nicholasville, Ky., Oct. 30. H. C. HERSPERGER.

A "HIGH-PRESSURE" A KIND WORD.

I received your letter telling me you would drop my name if I didn't renew my subscription at once; so I am aiming not to be dropped out of the finest class of people on earth, because I fully believe that they are the Gleanings family. Gleanings is one of the purest and cleanest of all the reading matter I have ever subscribed for. It is so straight against the evil, and so strong against it in every form, that it makes me love its pages. May God bless you all in your good work, and especially the dear old A. I. whose talks have done us so much good. You will find enclosed \$1.00 for the book I want, and Gleanings one year.

Jellico, Tenn.

C. WALKER.

THE OLD-FASHIONED RELIGION.

We always plan to read what A. I. Root says in the Home papers, Sunday evenings, as we are on a farm, and find it difficult to get to evening service. We endorse every word he says, and it does us good to know there are a few yet who hold to the old-fashioned religion.

Neenah, Wis., Oct. 16.

Editorial

In our issue for Feb. 1, Stray Straws had a corner cut out. The fact is, we did not get our usual batch of Straws (or supposed we didn't) and thereupon accused Dr. Miller of carrying them in his pocket instead of mailing them. The "goak" is on the editor this time, for he found the missing Straws under a pile of papers on his desk.

ONE MORE OF THE PIONEERS GONE.

We are sorry to announce the death of J. J. Ochsner, of Prairie du Sac, Wis. For a great many years Mr. Ochsner was one of the most extensive bee-keepers in his State, at one time owning six apiaries. His death, at the age of 83 years, which occurred January 15, was quite sudden, as his health was very good, owing to his firm belief in the value of fresh air and exercise. On the evening of January 10 he was reading to his wife, and had just finished reading our editorial notice of the death of James Heddon in the January 1st issue, when he was taken with a stroke of apoplexy, from which he did not recover.

Mr. Ochsner for a great many years was a reader of GLEANINGS, and we shall miss him as one of our most loyal friends.

HONEY STATISTICS, AGAIN; THE UNITED STATES CENSUS RELATING TO THE BEE-KEEPING INDUSTRY MISLEADING.

We failed to observe in our comments on the census returns, last issue, page 67, that certain States had made a great increase in the number of colonies over the previous decade. In this list we find Arizona, California, Colorado, Idaho, Iowa, Michigan, Montana, and New Mexico. It will be observed that this list comprises some of the Western States where irrigation is being opened up and alfalfa is being grown largely. In fact, in nearly all other States of the Union there has been a falling-off in the number of colonies. Yet in spite of all these figures more honey and beeswax have been produced in the last decade than during the previous period. This shows conclusively that the business is going into the hands of the specialists, and that those specialists are securing larger returns per colony. While it is true that producers in some of the irrigated

regions are not making as large an average as they did in the previous decade, owing to overstocking, yet the box-hive bee-keeper and the movable-frame bee-keepers who don't read the bee-papers, and secured anywhere from five to ten pounds of box honey have been eliminated, or almost entirely so. The elimination of nearly a million of colonies with a very low average production in the hands of such a class of bee-keepers necessarily brings up the average of colonies in the hands of the better class of producers. It is a case of the survival of the fittest.

PARCELS POST.

THE following editorial from the *Rural New-Yorker* for Feb. 3 is so much to the point that we can not do better than to use it, with the suggestion that every one of our readers sit down at once and write to his Senators and Representatives in Congress, and do it soon. Here is the editorial in question, from our esteemed contemporary:

Next week we begin the publication of the most striking article yet printed on parcels post. Prof. Price, of Ohio, is in Germany, and he will tell us in a plain, practical way just how the German parcels post is conducted and what it does for the German people. The time is just ripe for this, for now is the time to move upon Congress. There is a Presidential election this year. As they stand, both of the old parties are discredited in the eyes of the public. The leaders know this, no matter how they may bluff and bluster, and onside will outbid the other for popular favor if the demand can only be made clear. Here then is the opportunity for parcels post. If Congress can let it die there will be two or four years more of inaction. Right now, at the opening of this Presidential year, is the combination of time and the hour. Let every reader of the *Rural New-Yorker* realize this. It is the time to strike. Do not pass "resolutions" or sign petitions, but spend 20 cents or more in postage stamps and go right at the two Senators from your State and the Congressman from your district and tell them what you want. Do not threaten nor make any promises. Treat them as men—a little more prominent than you are, but still men with a good judgment of human nature. They will know when you mean business, or when you are chicken-hearted, and they will give you business or "taffy" as they size you up. No one can win parcels post for you without your aid. It will do little good to curse these men at home or at the store. Use the talking tongue to stick a stamp on a parcels-post letter.

HOW THE BEES ARE WINTERING; WHY WE ARE OPTIMISTIC.

SOME fears have been expressed by some of our correspondents that the severe winter we have been having may cause a heavy

loss. In answer to this we may say that so far conditions have not been unfavorable where the bees have been *properly protected*, indoors or out. The winter, up to the first of January, was very mild all over the United States. This put the bees in fine condition. Then it turned cold and stayed cold, with one or two rises of temperature—enough so that the bees could turn over in their sleep. The very severe cold that has been prevalent throughout the United States will mean an early spring if history repeats itself; and whatever the bees may have lost by reason of the cold will be more than made up by later conditions.

A condition that causes severe loss among bees are cold and warm spells in January or February, or both, during which bees get started in brood-rearing. A cold snap of two or three weeks after that is almost sure to have a disastrous effect; that is to say, an ordinary winter in January or February, followed by bad weather in March, is usually severe on bees. So far the weather this winter has been favorable rather than otherwise; for a *steady* cold does far less harm than warm and cold.

Examination of our own colonies, for example, about two weeks ago, showed all of them in splendid condition. At the present writing, Feb. 14, the United States Weather Bureau shows a letting-up in the cold.

It is fair to state that this winter will be disastrous on bees unprotected or in single-walled hives outdoors. On the other hand, it has been favorable for cellared bees.

CITY COUNCILS LEGISLATING AGAINST BEES; MAKING BEES STAY ON THEIR OWN PREMISES.

OUR attention has been called to a paper that is being circulated in the town of Gibsonburg, Ohio, for the purpose of getting the town council to pass an ordinance prohibiting the keeping of bees within the corporate limits of the village. We obtained the names of the mayor and president of the council, and wrote letters to them, explaining the important position that bees occupy in the fruit-growing industry by pollinating the blossoms. We showed that the few bees kept in town are probably only a very small part of those kept within a distance of a mile or more; that, even if those in town were removed, the chances are that there would be almost as many bees flying about as before. We concluded by stating that any such ordinance is unconstitutional, and cited the celebrated Arkadelphia case. The history of this famous case was written up by Thos. G. Newman, then General Manager of the National Bee-keepers' Association, and we sent them a copy of the pamphlet.

Last September we wrote to the mayor and councilmen of Huron, Ohio, where an ordinance had already been passed compelling all bee-keepers (and we believe there was only one) living within the corporate limits to screen the bees in the hives during July and August!

There are often local ordinances prevent-

ing any one living in a village from allowing his chickens to have a free range over his neighbors' lawns and gardens. No one objects to this; but suppose there were a hundred poultry-raisers situated just beyond the limits of the corporation, and the chickens in all of these yards were allowed free range over the town—how much good would it do to build fences around the few chickens kept in town? The absurdity is all the greater in the case of the bees, as they would die if fenced in so long, and they do no real harm any way.

Just the other day a gentleman gravely told us that he used to raise a great many grapes, but that it was no longer profitable, because bees from somewhere stung all his fruit. These stories, believed and repeated by intelligent people, are enough to make one think the whole world has gone daft.

In several instances where drastic measures were being taken by grudge-holders in towns or cities, we have been able to offer some help by way of writing letters, as mentioned before, to the mayor or councilmen. We shall be glad to do this at any time, for we have some strong literature bearing on the subject, that shows that bees, instead of being opposed by the intelligent fruit-growers, are actually welcomed by them. They are asking to have the bees put in their orchards.

THE BEE-KEEPER AND POULTRY-RAISER.

WHILE we are in hearty sympathy with the advice of the late W. Z. Hutchinson, "Keep more bees," for some specialists, the far greater number of bee-keepers, for one reason or another, can not go into the business extensively enough to make it worth their while to devote their whole time to it. For example, in many localities bee-keeping on a large scale would not be profitable, because the bee-pasturage is limited, or because the seasons are too uncertain.

Then there are others, like Mr. Louis H. Scholl, for instance, who like to have some hobby aside from their main business, to provide a change of thought and work and a certain amount of pleasure. There are still others who have the ability to become specialists in some other business at the same time that they are specializing in bee-keeping. To all such we would recommend poultry-raising; for, in our opinion, there is no other line of work that dovetails so nicely with bees. As has been pointed out by several of our correspondents in this issue, one who is capable of making a success with the bee business is also capable of succeeding with poultry, and *vice versa*.

An objection that is frequently made against combining two kinds of business is that one interferes with the other, so that the best results can not be secured from either. This may be true to a certain extent with bee-keeping and farming, bee-keeping and fruit-growing, etc.; for when the bees require the most attention and thought, there is need of "all hands" on the farm or in the orchard. But with the

poultry business this objection does not apply, for chickens require perhaps the least attention when bees require the most.

He is an extensive bee-keeper indeed, in the Northern States at least, who can keep his time profitably spent during the winter. It is true that some bottle and sell their crop through the winter months, but so few producers have the time to make a specialty of selling that we do not find more than perhaps one bee-keeper in a hundred who utilize their winters in this way. A certain amount of work is required, it is true, in preparing supers, repairing, and, in short, getting ready for the next season; but this should not take all of the time by any means.

A poultry-man, along in January, is usually very busy starting incubators, getting brooders ready, etc. Later in the season, as the chickens become older, it is possible to have more and more of the work done by an assistant, so that the bees may receive their share of attention. Thus the two lines do not interfere with each other—a fact which is proven by the constantly increasing number of producers of “honey and eggs.”

WHY THE CLOVERS DO NOT YIELD HONEY AS THEY DID IN YE OLDEN TIMES; CLOVER-SICK SOIL; LIME THE SOLUTION.

In our last issue, under the general heading of statistics relating to bee-keeping in the United States, we said we would have something further to say on the subject of clovers, and why they do not yield honey as formerly. We have heard a great deal concerning clover-sick soils; of land that will not grow red clover, but will grow alsike.

Many farmers who do not read the up-to-date farm papers have allowed their farms (as well as themselves) to become poorer and poorer until they have had to sell at a fearful sacrifice. For some reason, they do not know why, their farms have all “run down.” Farms that used to yield their fathers and grandfathers big crops of clover, now yield sparingly. Something is wrong. “The land is clover-sick—no good; might as well sell out and get a job in town.”

Later on, some up-to-date young farmer who has been to an agricultural school, or who thinks it pays to read progressive farm papers, comes along and buys one of these old farms that, through lack of knowledge, has all run down. Mark the change. In two or three years this “book farmer” (whom his neighbors ridiculed, perhaps) makes it as productive as when the country was new, or perhaps, in some cases, even more productive. How does this all come about? First of all, he begins to study the soil. He discovers it has been robbed, year in and year out, of some of the essential elements that make plant life grow. While stable manure has been applied, it does not supply every thing needed. In many cases these young farmers have found that the continued cropping of clover, year in and year out, has robbed the land of the

lime naturally in the soil until it has become too acid to grow clover as it should. In other cases, some other elements had been taken out.

It is getting to be the practice now among up-to-date farmers to send a sample of soil to the nearest experiment station in order to have it analyzed. In many cases the report shows a deficiency of lime; and when a farmer can not grow clover on his land in rotation with other crops he is in a bad way. Land that will grow alsike better than red clover shows a deficiency of lime; for alsike will grow on a more acid soil than red clover. The deficiency of lime in many soils has enormously increased the growing of alsike; and this has been of no small benefit to the bee-keepers. In some ways it may be better to let the farmer be in ignorance of the cause; but at this rate the soil will become too acid for even alsike.

Nearly all of Northeastern Ohio and the major part of Pennsylvania show a deficiency in lime. The same deficiency has been found in other States; Massachusetts, for example, doesn't yield any clover honey to speak of. The progressive farmers find they are able to remedy this condition by putting in lime; and when we can grow clover as we did in the days of our granddads, we shall have clover honey as they did. Unintelligent farming on the part of the don't-read-papers tillers of the soil has ruined many farms in the country. Their owners are badly in debt, and complaining of hard times. If there ever was a time when a farmer *ought* to be prosperous, it is right now; and any farmer who does not read a good farm paper is losing the great opportunity of his life to pay off those old debts and put aside a comfortable sum to take care of old age.

This sounds a good deal like an editorial for farmers; but the facts are, it is written for the farmer bee-keepers—not because they need the information, but because they need to get after their neighbors who are not reading papers. By so doing they can very greatly increase their clover pasturage, and clover pasturage means honey. In the mean time, we invite every bee-keeper, or any one else who reads these pages, to send to his nearest experiment station for bulletins on clover-growing and liming the soil. While it is not contended that lime is the only thing lacking (because clover will generally continue to grow some in spite of acid soil), it *is* contended that lime, where the soil is acid, will make it vastly more friendly to the clovers.

The editor had the pleasure of listening to Alva Agee at College Station, Pa., at a farmers' institute recently; and if there is a man in the United States who seems to understand this problem of making clover grow, through the use of lime, Mr. Agee is the man. Joseph Wing is another great authority. In later issues we hope to present something more from these men, particularly on *how* to lime the soil and what kind of lime to use.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

MR. EDITOR, please look at the sticker on the envelop that contains these Straws. It reads, "WE WANT the United States Government to establish a *parcels post*." These stickers can be had for \$1.00 a 1000 from "Parcels Post League," New York. [Good suggestion. See editorial elsewhere on the subject.—ED.]

BEEES WILL build queen-cells when the queen is caged in the hive "about the same as if she were out of the hive entirely," p. 58. I suppose that "about" means that cells will be started sooner, and more of them, if the queen be out of the hive entirely. [We accept your modification or correction.—ED.]

LOUIS SCHOLL gives alfalfa as an example of honey with decided flavor, page 38. I've been buying alfalfa to use in hot drink, as being nearest a pure sweet without flavor, but I've lately had some with too much flavor. Wonder what is the rule about flavor in alfalfa. [Alfalfa varies somewhat in flavor, depending on the locality where it is produced. In the southern irrigated regions it is apt to be a little darker, and perhaps a little stronger in flavor. In the more northern regions the color and flavor are improved. In some localities there is enough sweet clover and mountain sage in alfalfa to mellow its taste. The same conditions that affect alfalfa apply to clover—that is to say, there is white clover and white clover—some extra fancy, most of it good, and some of it poor or "off."—ED.]

"EVERY modern yard nowadays has a scale-hive," p. 48. S-s-say, Mr. Editor, do you mean to insinuate that my bee-yard isn't modern? Well, if you will insist, I suppose that part of the yard isn't as modern as it might be. [Yes, sir, 'e. Put up a scale hive. You may have a modern yard, but it can not be clear up to date unless you have a honey-barometer, so to speak. We have been in many yards where the owners would about as soon get along without a veil as without a scale hive. If the colony on the scales is a fair average one, neither the best nor the poorest, it enables the owner to keep pretty close tab on the flow of nectar. For example, if a drouth is on, and the nectar supply begins to show a rapid falling-off, the bee-keeper will not put on any more supers. But if the weather conditions are ideal, and the scale hive shows a big gain every day, the bee-keeper will take the opposite course.—ED.]

YOU ASK, Mr. Editor, page 69, if I might not find outdoor wintering to my advantage if I should try it again. Entirely possible. Not very probable. I've always had an idea that bees wintered out in the open air would be more rugged than when in the close air of a cellar. Then there's the gain

of earlier breeding. But with a furnace in the cellar my bees have perhaps as pure air as outdoors. The earlier breeding makes some colonies stronger, but it also kills some colonies. At any rate, it is morally certain that I would have a loss every winter from wintering outdoors—some winters a heavy loss—while in my well-ventilated cellar I don't expect to lose a single colony from wintering in any winter. What's best elsewhere might not be best for me. [It would hardly pay you, evidently, to make any change; but a large number (mostly beginners) are not having success with indoor wintering. To all such, if located in a severe climate, we would recommend wintering four hives in one large case, as practiced by R. F. Holtermann, J. L. Byer, and H. G. Sibbald, of Canada, with such marked success. See pages 693 and 694, Nov. 15th issue. Where climates are extremely cold, these big winter cases, we believe, for four hives are the equal of any cellar.—ED.]

THAT EDITORIAL, p. 35, sets one to thinking. But if comb honey is so scarce, why don't quotations show it? In GLEANINGS the highest for comb is 18 and extracted 12. Hardly any thing in that to induce extractors to take up comb. It may be said that comb is a luxury, and above a certain price will not be bought. But it didn't work that way years ago when it was higher than now, and kept with the price of butter. It's too much of a muddle for me to understand. [Market quotations at the present time do not give the true index of the situation. Early last season there was a big demand for comb honey that could not be filled. Buyers, fearing that a large crop might be held in reserve, did not offer high prices, as they feared being overloaded. Shortly Western comb honey began to come in, and prices on comb honey that would have advanced were held stationary. Several buyers have told us that they could have sold ten times the amount of comb honey if they could have gotten it when there was a call for it. The best demand for comb honey is in the fall and before the holidays. If there is no comb honey to speak of, consumers will go without. If, on the other hand, we bee-keepers will raise more comb honey, and have it *ready in time*, we shall have no trouble in selling it—that is, if it is of good quality. At the present time there is just enough comb honey held by one or two large buyers to hold the market fairly even. But the point is this: There is always a good demand for more comb honey early in the season. In seasons of plenty the early shippers will dispose of their crops at good prices, while late shippers, if they wait till the holidays or after, may be hunting a market. Comb honey, however, is getting to be more and more of a staple.—ED.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

A capital idea that, in a footnote, page 712, Dec. 1, regarding the value of a mat of corrugated paper on top of sections. When the case is handled bottom side up the combs will rest on a soft mat.

That picture on the cover of the Dec. 15th number is very pretty; but it almost made my back ache to look at it, to think of the work required to inspect such a lot. A lot of fifteen or twenty, four inches apart, is bad enough without a roof over them.

Mr. Byer's appreciation of the value of dry sawdust for a cushion on top of the hive, p. 713, Dec. 1, is creditable to his good sense; but after having used sawdust for many years we have come to the conclusion that fine planer shavings are better.

Passing through the markets of Washington one day this week I saw a two-story shipping-case of the style Mr. Foster, of Colorado, has so ably defended, and I must confess it was a very attractive package; but I noticed that three of the six combs visible through the glass were broken loose from the wood.

Stopping near Howard University, a college for colored people, I was awakened early Christmas morning by the colored students singing Christmas carols, and it seemed almost as though the sky had again opened, and the angelic hosts were singing "Peace on earth, good will toward men"—a beautiful custom, surely.

Let me add my testimony to the value of windbreaks for wintering bees out of doors. In our climate I would go some distance to locate a yard of bees where there would be protection, after seeing a part of two yards wiped out where exposed to the wind while the rest of the yard wintered very much better. See page 675, Nov. 15.

I have noticed a good deal of discussion of late as to whether a two or three inch glass is best for shipping-cases. It has been many years since cases with glass have been used here in Vermont, and I am wondering how large a proportion of shipping-cases manufactured in supply-factories are made with a two or three inch glass side.

Wesley Foster tells us, page 647, Nov. 1, how to introduce queens by baptizing. Very good. I believe it was A. E. Manum who told in one of our State conventions many years ago how to introduce a virgin queen by giving her a second birth by caging her in a queen-cell and letting her gnaw out like a young queen, and they accepted her the same as a young queen.

On page 713 Mr. Byer expresses the idea that alsike clover is not a drouth-resister. Well, perhaps not as good as red clover, but, mercy me! how it can stand water! Red clover is nowhere in comparison, and I have noticed that, during a wet season, we usually have alsike clover, whether it could be seen on the ground the fall before or not.

Our friend Wesley Foster never seems to lack for good common sense, and his ideas on the value of reinspecting and the qualifications of an inspector are well worth reading, page 714, Dec. 1. It is certainly a great deal easier to burn hives of bees, and to be spectacular, than to teach bee-keepers patiently how to cure and care for their bees.

Mr. Gates' article, page 717, Dec. 1, is of great interest. I noted especially what he has said on the wastefulness of feeding bees in the open air. I believe we have a good deal to learn yet as to how much waste such feeding brings, and what is the character of the little drops that the bees let fall on their way to their hives. I am yet to be convinced that it is water they have separated from the sweet syrup.

Looking over the government green or propagating houses in Washington, I found that tests were being made of a large number of seedling melilotus clovers, or perhaps varieties, in order to find one with a very small amount of the characteristic bitterness. If successful in the experiment it may be used more extensively than at present as a forage-plant. If it should come into general use it will add much to our honey resources.

Mr. Chadwick, on page 748, Dec. 15, tells how the ranges of sage in Southern California are being plowed up and the bee-forage destroyed, and predicts the time when the waste places will be covered by plants of greater economic value. Let me say that I saw in Washington, alfalfa from Northern Africa that will grow where there are only three inches of rainfall, and another variety that required an alkali soil for thrifty growth. Still another from Northern Asia thrives where it is so cold that the ground never entirely thaws out.

The editorial on page 710, Dec. 1, on the value of shade, is full of good sense. I have contended in the past, I believe, that bees do as well in the shade as in the sun; but by watching I have discovered that there is a decided difference in favor of those shaded but little and those in a dense shade. "Confession is good for the soul." But I should think Mr. Robertson, page 725, used more shade than is necessary for his climate. For those having outyards, I fear his methods would not be practical.

Bee-keeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas

BEES AND CHICKENS; HOW THEY WORK TOGETHER.

I have decided to have something to say on this subject because it is the special theme of this issue, and because I have found that the combination of bees and poultry can be successfully followed, even by the extensive bee-keeper. In my case, I was much interested in pure-bred poultry even when a mere boy, and this interest has been the first incentive for keeping some poultry for a number of years. When my bee business was enlarged to greater proportions, so that it became a real business that was quite strenuous at times, especially during the rush of the season, the old slogan so often repeated, that "a business man should have a hobby to ride to take his mind away from his business cares," became one that received no little attention. Possessing that natural love and interest for pure-bred poultry, and seeing profitable possibilities in it besides the mere recreative value as a "hobby" to ride, besides already possessing a beginning in the dozen or more fowls in the back yard, poultry-breeding was adopted immediately.

I have ridden this hobby so successfully that my yards of Barred and White Plymouth Rocks, Rhode Island Reds, and White Wyandottes, are the best in the community, and are admired by many visitors who come to see them. The appreciation of this success has culminated in being chosen among the many poultry-raisers here as president of our poultry and pet-stock association.

The profits so far have not been large, on account of the initial investment necessary in the venture, which was really begun as a hobby rather than a paying dollars-and-cents business, but it has been a remunerative one from the very start.

It may be well to state that my beginning with poultry was just the same as that of my bee-keeping career. I had only a few fowls at first, just as I began with only a few colonies of bees. From this small start I began the upward climb on the ladder of success, as experience and better knowledge of what to do were acquired. I mention this to show the importance of beginning small and then growing into the business.

As a combination rightly managed, bee-keeping and poultry-raising may be profitably followed, even though neither line be restricted to the plane of a hobby. My own experience has left me without a doubt on this question. But it will be well to bear in mind that not all persons can manage too many irons in the fire, and such should not attempt the combination. Some reach their limit very easily with only a few hundred colonies of bees and no more, while some who could manage more bees can not look after two lines of business entirely different.

For those who want a "hobby," the keep-

ing of pure-bred poultry will fill a good place, and by those who want to combine bee-keeping with some other side line this combination will be found profitable if they are able to look after both properly. Those who find it better not to combine any thing else with bee-keeping should follow the late Mr. Hutchinson's motto, "Keep more bees," or my own, "Keep more better bees better."

MAKING A BEGINNING WITH BEES.

The cover design of the January 1st number of GLEANINGS was most appropriate for a beginner's number. It answers in picture, better than words can explain, the question so often asked, "How can I best make a beginning with bees?" The picture shows it. Order a two or three frame nucleus with a good queen of Italian bees from a reliable bee-keeper or queen-breeder. This will be shipped in a light crate by express so the shipping charges need not be very high.

In the mean time prepare a ten-frame hive. Have it nicely painted, and all the frames filled with full sheets of comb foundation except the two or three that will be replaced by the combs of the nucleus ordered. This hive should be nicely located in the shade of a tree where the morning sun brightens and warms up the hive in the fore part of the day, but where it is protected from the heat later.

With the hive material, have ready a good smoker and a bee-veil, so necessary in handling the bees. The smoker should be well started, ready to be used at the proper time, even with the gentlest bees; but the veil may be kept about the crown of the hat so that it can be pulled down over the face in a moment, in case of an emergency.

All in readiness, when the nucleus arrives take it to its new place of abode. After the veil has been adjusted, bring the smoker into play, blowing just a little smoke over the bees as the shipping-crate is pried open and the nucleus placed in the hive. Of course, you must admire the beautiful bees as the combs one by one are carefully handled. The next thought is, How does the queen look? To some it will be a little difficult to find her at once; but a little practice will soon enable the beginner to spy her very quickly. When the combs are all in place, the hive closed up, and the rest of the bees shaken out of the crate in front of the hive, it is a pretty sight indeed to watch them enter the new home with a loud hum of gladness as they fan the air with their raised wings.

If flowers are in bloom and nectar is plentiful, the bees will soon make progress and will build out the foundation into beautiful straight combs in the rest of the frames.

All this, and more too, is brought vividly to our minds by gazing at that cover design. A better one could not have been chosen.

BEE-KEEPING IN CALIFORNIA

P. C. CHADWICK, Redlands, Cal.

January is rapidly passing, with little rain of any consequence, and barely enough moisture to keep the surface growth alive. We have only about eight more weeks in which we may reasonably expect rain, making the outlook at best rather dark.

A book that I value as highly as any in my library is "Langstroth on the Honey-bee," published in 1870, two years previous to my birth. It was presented to me in 1886 by Mr. E. A. Rhea, of Loring, Kansas, and was the foundation of my knowledge of bees.

A capping-melter is not a great necessity here. If there is sun enough to warm the air sufficiently to extract, you can usually get your cappings melted in a solar extractor; and what little honey goes out with the drained cappings will very likely come in handy to feed weak colonies later on.

Those in reach of the orange may get the usual orange flow, for the month has been exceptionally warm, and breeding has started in earnest; many queens have spread three or more combs of eggs. I consider this of no advantage to those on sage ranges; for if the dry weather should continue it will cause heavy breeding, which will mean large consumption of stores that may be greatly needed before another season.

I was offered 25 cts. for the best wax delivered at Los Angeles, but an eastern buyer offered 28½ cts., F. O. B. I wrote to Los Angeles, regarding the other offer, and received this answer: "Your party who is offering 28½ cts. is, in our judgment, over-shooting the mark." I shipped the lot, 202 lbs., east and received check for \$57.57—\$7.50 more than I could get in Los Angeles. Most of our Southern California wax finds its way into Los Angeles, where at times the receipts are quite heavy, and prices slump beyond reason.

During the winter many sojourners from various parts of the country, who are interested in bees, have called on me, and I have enjoyed these visits very much. To those who may yet come, I would ask that you call at my home, 725 East High Ave., after 7 P.M., where you may have an hour or two and welcome; but do not expect me to beguile to come to our State, or you will be disappointed. If you are succeeding where you are, why change? If not, find out the reason, for it may be your own fault, and a fault not easily cured out here. There are more paying locations, not taken, in many States east

than there are in this State. You of the East have cold winters, to be sure; but loss from actual cold is much less than the average bee-keeper thinks; for every colony that dies is said to have "winter-killed," regardless of other conditions. Our normal mortality rate here is over 10 per cent.

My first bee-hive was a "George"—the only one, to my knowledge, ever manufactured on a rush order by this process. George, whose last name is Kutehenthal, had been married to my sister but a short time, and had not acquired a very large stock of tools. I was helping him plant corn on my fourteenth birthday, when I found a swarm of bees on a bush—the first swarm I had ever seen. I wanted them badly, but had no hive. George came to my rescue with a sharp hatchet and a 1×12 rough pine board. He soon had a hive chopped out and nailed. The hiving was successfully accomplished, and the foundation laid for my first apiary. Thanks to George.

The advisability of compensating for colonies destroyed by inspectors, mentioned by J. L. Byer, p. 5, Jan. 1, like all questions, has two sides. There have been cases in this State where inspectors have been guilty of no less than wanton destruction of property in their over-zealousness to enforce the law. On the other hand, some have been so grossly negligent that conditions in places have become deplorable. An inspector should be a man of good judgment, and should try, as far as possible, not to destroy any thing of value. Several cases have been called to my attention where quantities of hives and combs have been burned. There is no excuse whatever for such drastic action. The wax and hives are not diseased, and, if thoroughly boiled, could be saved.

Our so-called State association has been called for Feb. 6, 7, 8, at Los Angeles, which will be long before this reaches the readers of GLEANINGS. It is my earnest hope that the various organizations over the State may be amalgamated into what may be properly called a State association, our so-called State association being in reality no more than a Southern California organization, and should be so termed until all our smaller ones are included with us in one grand and truly State organization.

Since writing the above, GLEANINGS has come to hand, and I have read the words of Mr. Harry K. Hill, page 55, Jan. 15, and for the most part I agree with him. The northern brothers feel that it is a case of the tail trying to wag the dog, which belief, I believe, is not entirely unfounded.

Conversations with Doolittle

At Borodino, New York

KEEPING LOTS OF BEES.

"How many colonies of bees should one keep to be a well-to-do apiarist? I became interested in bees two years ago, and bought five colonies. I have fifteen now; and my sales, since I began, have been about \$156. I have been figuring a little on keeping 50 colonies, and from my experience so far I thought I might average \$500 a year from that number; but I have just read that no apiarist becomes well-to-do unless he keeps a lot of bees. The writer of the article advocated keeping several out-apiaries, numbering from 50 to 100 colonies each, besides having as many colonies in the home apiary as his field would support. If I must engage in bee-keeping on such a large scale in order to become well-to-do I shall feel somewhat like abandoning the whole thing."

"Much will depend upon the way you interpret that expression, 'well-to-do,' as well as the meaning of those four words, 'a lot of bees.' We will consider the last four words first. Some would construe these to mean a lot of bees in each colony. How often has it been reiterated that a colony of bees numbering from 50,000 to 75,000, and even 100,000, produces the best results, while one from 10,000 to 15,000 gives its keeper little if any surplus! In spite of the prevalent idea that bees work for nothing and board themselves, the colonies numbering between 10,000 and 20,000 are the rule rather than the exception, and, consequently yield only a small surplus, even though a bee-keeper may count his colonies by the hundreds or thousands.

"With such small colonies a much greater proportion of the whole colony must stay at home to care for the inside needs of the hive, thus leaving few fielders, than in case of the colony having 100,000 bees where 10,000 can care for the inside work, and 90,000 can go to the field, thereby rolling in an amount of honey that is sure to insure success.

"Then, too, these 90,000 fielders should come on the stage of action at the right time for the best nectar-yield, whether from clover, basswood, buckwheat, or what; otherwise they may not be as satisfactory as the smaller ones; for 90,000 bees on the stage of action at the end of any flow of nectar become consumers instead of producers; and unless another flow comes before they live out their 45 days of useful life the stores of the hive will constantly decrease, and the keeper of such colonies be compelled to feed for winter. From a financial standpoint the man who can keep 500 or 5000 colonies of bees so that each colony will have from 75,000 to 100,000 active fielders when the main flow of nectar is on, will far outshine the man who is contented with only 50 colonies.

"As to the expression, 'well-to-do,' suppose there is a bee-keeper who is capable of

bringing up to the necessary standard 500 or 1000 colonies of bees in several out-apiaries, and that he is able on the average, year after year, to do as well with them as our questioner hopes to do with 50 colonies, his income each year would be from \$5000 to 10,000, and, doubtless, in the eyes of the world he would be considered well-to-do. Yes, and I must confess that, by the great majority of the masses, this would be the feeling; for in the up-to-date newspaper lengthy articles are devoted to one who has been separated by death from his millions, but merely a scanty inch in some obscure corner is given to the one who has secured *eternal life* by believing on our Lord and Savior Jesus Christ, with a fortune in this world of only \$100 left for his burial.

"But let us come back to our questioner: He can keep his 50 colonies without the extreme exertion, racking of brains, and the muscle required by a larger number. He can have time to examine into the minutiae of affairs inside the colony; to go into scientific research, to study nature, and, from this, nature's God. In short, his powers can be spent in the uplifting of himself and those about him above the sordid things which come to the one whose only god is money. But can a man be considered 'well-to-do' with an income of only \$500 a year? The majority of the families in the United States do not have that income, and many of the preachers of the gospel, who are successful in winning many souls for Christ, do not have a larger salary. A good definition of 'well-to-do,' from my standpoint, would be, contentment, with godliness, is great gain."

[Mr. Doolittle is absolutely right when he emphasizes the importance of a large force of bees of the right age *in time* to go to the fields. We also wish to indorse his sentiments regarding the "well-to-do man."—ED.]

Cotton Smoker Fuel.

It is unfair to jump on a fellow just because he has said something you *think* isn't so; but when you walk all over him afterward it is stamping it in. You fellows can keep right on using cotton rags and waste for smoker fuel. It's wholly your party; and if you prefer the sort of fun which it brings I wish you happy days. Greasy cotton waste is an entirely different proposition, and I didn't say any thing about it, but merely talked of cotton. The grease gives a very different result, also a stink; and, furthermore, greasy waste is prone to spontaneous combustion—particularly so with some oils. A handful of it in a workman's pocket called his attention to its presence by consuming a sizable portion of the front of his overalls and trousers, and anointed him with a large and rosy blister. Happy days!

Well, boys, if you will fill two smokers, one with cotton rags or dry waste and another with burlap or wood in some form, then work ten colonies with one, then ten with the other, and so on, you may be inclined to leave me alone and let me catch my breath. If you can not wait to try the trick, ask Latham.

Providence, R. I., Jan. 29. ARTHUR C. MILLER.

General Correspondence

BEES, POULTRY, AND TRUCK-GARDENING IN FLORIDA.

BY FRANK M. BALDWIN.

My experience last October may help the readers of GLEANINGS to form a better judgment of this part of our great country. I came into this section in June to do some preaching; found surveying also, and have been here most of the summer. After preaching Sunday at Palmetto I took an early train Monday to inspect seventy-five colonies of bees on the edge of the Apopka Marsh, in Orange County, that Mr. W. S. Blaisdell had offered for sale. Mr. B. is old and infirm, and wants to convert his apiary into cash.

He was awaiting my coming at Gainsboro Station, and soon we were journeying behind his mule, toward his home, three miles away on the banks of the canal that was made for the purpose of draining the 50,000 acres composing the big marsh. This tract is rich sawgrass land, similar to the Everglades. The effort to reclaim it was not successful. The canal must be dug deeper and wider. Darkness overtook us just as we arrived at the house, and on this account the examination of the bees had to be postponed until Tuesday.

INSPECTION OF THE BEES.

The morning's inspection revealed a fine healthy lot of bees in old and worn-out hives. The style and sizes are original with their owner, and have given him the best results. He makes them from native lumber, much of it undressed. They have served him well for seventeen years, but are no longer strong enough to withstand three miles of jolting in wagons over rough roads to be followed by 150 miles in a freight car. The thought of buying and taking them to Parish was reluctantly abandoned. They were strong in bees and brood, in just the right condition to gather the honey-flow from goldenrod and myrtles. Mr. B. expected to extract three tons of superior honey from them within the next sixty days. He usually gets two crops—one from saw-palmetto in the early summer, the other in the fall. Last fall the marsh was too wet, and he got no surplus. This year conditions are more favorable than usual, and he hopes to make up in some measure for the failure of the palmetto in May and June. He is not near enough to any groves to get the benefit of the orange-bloom in February. It is only once in seventeen years that the two flows have failed him, and I believe he has never had to feed his bees.

Mr. Blaisdell took me down to see the old drainage canal. On the banks I met and talked with Mr. Belamy and his son, who are making a living from four acres of extra good truck land, and are salting something down in the bank. They use no fertilizer

and grow no celery. All other Florida vegetables are planted by them and sold at a local market. They rarely ship north. Three small towns within twelve miles of their patch take all they produce.

Mr. Blaisdell has 27 acres of rich land that his bees have paid for; and his neighbors say his industrious insects have paid for the fertilizer and labor he has wasted in his attempts to grow and market vegetables. Here was a convincing illustration of the truth that one must find out what he can do best, and devote himself to that. Truckers and bee-keepers are born rather than made.

TRUCK-FARMING.

At noon the train was again boarded. This time the destination was Sanford and the fall meeting of the Presbytery of St. John. While there Mr. and Mrs. Rosetter entertained me with true Southern hospitality. Mr. R. has a truck-farm of 40 acres, three miles in the country, which he and his son operate. He lives in town and the son on the farm, though both of them spend all the daylight hours in the field with their hands. Six helpers are employed all the year, and in the busy season as many as forty are at work. Lettuce and celery are the principal crops, and the seed which was sown in the beds several weeks ago is now up. The former will soon be transplanted into land which is now being carefully prepared for it.

Early Thursday I went with Mr. R. to the farm and enjoyed a two-hours' inspection of the seed-beds and the well-tilled ground. The seed-beds are more than half a mile in aggregate length, and are tended with great care. Lettuce requires ninety days from the time of planting until ready for the market; and celery about six months' time and labor. Beans, potatoes, etc., follow. Then corn is planted. This year this—the third crop on the land—yielded more than fifty bushels to the acre. This intensive farming calls for a ton of fertilizer to the acre.

There are ten artesian wells on the land, and rows of small tile have been laid 20 feet apart and 18 inches deep to use their water in sub-irrigation. Four thousand dollars' worth of boards for blanching celery are stacked up in great piles near the many buildings. These last, together with the many wells, tile, and other improvements, have called for an outlay of \$28,000, over and above the cost of the land (a rather large investment on forty acres). When, as in 1909, the crop brings less than it costs to raise it, the feeling must be rather bitter. But they do well most years. Once they netted \$12,400 from 16 acres.

The Sanford Board of Trade, to show what is being done in this favored region, took the Presbytery for a launch ride across Lake Worth Wednesday afternoon, and for an auto ride among the celery-farms Thursday.

A POULTRY FARM.

Mr. Throop, a man nearly seventy years old, has *three thousand* White Leghorns on his poultry-farm at Enterprise. He was feeding them corn. He is hale and vigorous, looking less than fifty. He keeps 2000 laying hens. One-third of the present flock are not old enough for the laying-pens. His birds are in fine condition. The old ones have about finished moulting, and will soon be "shelling out" lots of eggs. The average is 130 a hen per annum. The eggs sell at 35 cents a dozen to regular customers. Feed and corn cost from \$1.30 to \$1.40, according to the price of grain. Mr. Throop prefers to buy rather than grow feed. As the care of his flocks calls for all his time, he lives among his birds. They need constant attention 365 days in the year in order to net \$2.40 per hen. Two thousand times \$2.40 is an attractive income. But don't drop every thing and rush into poultry, for you may not have the genius for many details, some of them very unattractive, that make success in that business. Poultry-keepers are like truck-growers—born with a gift for it. Go very carefully until you find out what you can do, then go your length at that. Many have tried to imitate Mr. Throop. They are now sadder men, and, let us hope, wiser ones.

My judgment after two years' experience in Florida is that it is the land of opportunity for a great many. Yet it will bring loss to more than it will bring benefit. Its climate is its greatest asset. Do you need winter warmth and comfort? Have you the money or the energy to grow truck or develop an orange-grove? Come down. You will find the climate everywhere. The proper location for the others must be carefully sought. Much time and investigation must be given to it.

Parish, Fla., Oct. 16.

SYSTEM IN BEE-INSPECTION.

BY WESLEY FOSTER.

I am enclosing an inspection-report card which I have gotten up from suggestions received from the State Entomologist of Indiana, and from Dr. Phillips. The object of the cards is to save making a second inspection in every case. As Dr. Phillips says, the more we can accomplish in making each bee-keeper realize the importance of doing what he can to stamp out the disease, the more valuable will the inspection be as an educative force.

The cards, when torn along the perforated line, are card-file size, and can easily be kept for reference. The top-card is filled out by the inspector and signed on the back by the bee-keeper whose bees have been examined. This top card is then torn off and retained by the inspector, as it contains a record of the work done as well as a signed statement that the bee-keeper will treat the colonies that are diseased.

The lower card is filled out and given to the bee-keeper as a notice to treat all diseased colonies. The bee-keeper, when he has treated the bees, signs the statement of treatment and mails the card to me. The inspector in the meantime has sent the top card to me so that, if I do not receive its mate within the time allowed, I can write him to learn whether the bee-keeper has treated the colonies, or I can write directly to the bee-man, asking for an explanation for not receiving the statement of treatment as agreed.

I have used this plan in some of my inspection work this past fall, and it works well. The only difficulty is in getting a prompt report from the bee-keeper. Some have to be written to once or twice before sending in the statement of treatment.

The limit of time in treating colonies has been placed at ten days, though there will be cases where less time will be given, and some cases may arise where more may be given. This matter rests with the inspector.

OFFICE OF STATE ENTOMOLOGIST

WESLEY FOSTER, STATE BEE INSPECTOR, BOULDER, COLORADO.

The Bee Inspector has this day examined the bees belonging to and found colonies affected with foul brood. All bees having any form of foul brood are to be treated as indicated on the back of this notice.

STATEMENT OF TREATMENT.

I have treated all the bees mentioned as diseased above, and have carefully followed the directions.

Signature of bee-keeper.

Mail this card, as agreed, before191, to Wesley Foster, Boulder, Colorado.

Lower card (back).

TREATMENT FOR FOUL BROOD.

In the evening, after the bees have quit flying, brush or shake the bees from the old combs into a clean hive containing no drawn comb.

Burn all the old combs *at once*, not the next day. Do not allow even the smallest drop of honey from the diseased colony to be exposed to robbers, or the disease may be carried back to the healthy colonies.

The hive bodies, covers, and bottoms may be saved by scraping all wax and propolis from the interior surface and charring with a blaze from kerosene poured over the inside of the hive.

If no honey is being gathered from the flowers, the treated colonies should be fed or given combs of honey from healthy colonies to fill their hive, after the bees have been on the starters for at least 48 hours.

DUCKS AND DUCKLINGS DOWN IN FLORIDA.

More about the Duck that Laid 100 Eggs without a Miss.

BY A. I. ROOT.

[To the question, "What occupation goes the best with bees?" we have often replied, "Poultry-raising;" but W. Z. Hutchinson's invariable reply was, "More bees." If our senior editor, the writer of the following article, were asked what occupation goes the best with poultry-raising, we fancy he would say, "More ducks."—ED.]

On page 61, Jan. 15, I said the duck that gave the 100 eggs without a miss was still laying. Well, to-day, Jan. 22, she is still at it, making nearly two months without a miss *this* winter. Of course, there is a possibility of a mistake; but as her eggs are of a slightly bluish-green tint, and also larger, than any of those laid by her daughters, a mistake is not likely. None of her numerous daughters have so far come up to her. Like the good woman described in the last chapter of Proverbs we can say of her, "Many daughters have done virtuously, but thou excellest them all."

While speaking of the size of duck eggs I believe it is usually the case that most of them vary more or less in size. Well, I am led to believe this is largely a matter of nutrition. For some time I had been leaving a pan of corn with them all night long; but finding the birds and rabbits were also helping themselves I covered their grain the

A. I. Root admiring his favorite Buttercup rooster.

last thing at night, and uncovered it at daylight. By so doing there was a saving in feed; but I soon felt sure the eggs were not uniformly as large. To get up a good-sized egg every 24 hours requires good nourishing food, and that *without stint*.

Up to Jan. 1 I was boasting among the neighbors that I was getting four eggs a day

The duck that laid 100 eggs without a "skip," together with her comrades, as they go out every morning on the drainage canal. The two with the dark bills are ducks, and the two with yellow bills are drakes. The drakes are also lighter in color.

from four ducks right along; but on Dec. 31 one of my laying ducks did not get home at night with the rest, and Mrs. Root then reminded me that one of our largest drakes failed to return the day before *Thanksgiving*. At the time, I explained it by saying the alligators must have taken him, as they were going up the canal nearly half a mile every day. By the way, Mrs. Root thought I had got it a little too strong when I said nothing was ever stolen in our neighborhood, and remarked, "Do you think it reasonable that an alligator would take a particular fancy for a fat drake just before Thanksgiving, and again for a duck just before New Year's day?"

Well, I still feel sure no one around here has harmed my ducks; but if they really were stolen I think it was done by strangers from afar, who are usually prowling about with guns at this season of the year.

Since Jan. 1 I have been getting only two duck eggs a day much of the time, the two younger ducks not doing as well as their mother a year older. One of them, after finishing her laying, wanted to sit, for about a week; but, notwithstanding, I am putting every egg under hens or in the incubator. Out of 51 eggs in the incubator, 45 were fertile; but I hatched out only 19 ducklings, most of the rest having "died in the shell." I wrote to Cyphers people about it, and they seemed to think I did not give the eggs sufficient cooling.

The incubator is running again with 47 fertile eggs, and so far (11 days) they seem to be strongly fertile. As I hatched only 19

I said to myself I would take great care and not lose a duckling; but just this morning (when they are 11 days old) I found one squeezed in between the fireless brooder and the fence. How could I have been so careless as to leave such a place instead of pushing the brooder clear up to the fence, leaving no vacancy? Perhaps "locking the stable door *after* the horse is stolen" is better than doing nothing; but I would give a silver dollar to have that bright lively little friend back to life again, and to cure the sting of a guilty conscience that follows me all the day long. The fireless brooder answers here beautifully with ducklings. At first for a few nights while it was quite cool I gave them a heated brick; but I am led to believe it was not necessary; for one night when it seemed warm I omitted it, and it turned suddenly cold with a trace of frost. They were only about four days old, and I went out just at daylight with fear (and trembling) that they might all be stiff with cold. Not so. As soon as the entrance was open, out they shot and took a run clear to the other end of their yard in the frosty morning air; and after a big feed they cantered about until the sun was up.

Now in regard to the pictures accompanying this article. If you will turn back to my "duck story," April 1, last year, you will get a much better idea of them. While on the train coming here one man remarked to another, pointing to me, "Is not that the chap that goes down to Florida every winter to raise ducks to feed to alligators?"

Eggs are now only 30 cts. a dozen, so that

The waterfall that comes down over the mouth of the "alligator cave." It is made to spread out like a great soap bubble by the stream falling on the smooth surface of an inverted five-cent fire-shovel.

The mother Leghorn hen that did not hesitate about tackling an open-mouthed alligator in defense of her ducklings. The waterfall and alligator cave are just behind her. The drainage canal is right on the other side of the poultry-netting.

it takes rather more than nine eggs a day to feed the whole lot; and the way the 18 ducklings are beginning to tease for their meal, bran, and middlings, wet up with sour milk, the feed-bill promises to get *still* larger; but as I am getting from 30 to 40 eggs a day they are paying very well after all. The ducklings are crazy for lettuce; and here in Florida, at least, it would seem that lettuce is almost as necessary for all kinds of poultry as wheat, corn, and oats.

GIVING THE WEAK-LINGS A FAIR CHANCE.

About a year ago I told you of a single duck egg that was under two different sitting hens, and was finally hatched in my home-made incubator. Before the egg was even pipped, the inmate would peep every time I tapped with my finger-nail on the egg. Well, after he

was hatched I put him with some incubator chicks that were several days older than the duck, and of course they "made life miserable" for him, especially at feed-

Another view of the Leghorn hen and her ducklings, giving also a glimpse of box with netting front, where they are secure nights from all sorts of "night prowlers."

"The house of refuge." Netting "protector," for giving the weaklings or younger ones a fair chance.

ing time. As he was younger; and as ducks must have soft food when first hatched, I tried to give him bread and milk; but, dear me! he was "snowed under" before he got a single bite of the dainty prepared for him alone. Finally I "got busy;" and with the aid of a barrel-hoop and some inch-mesh netting I made the very handy implement pictured above.

In the picture it is shown placed over the ducks hatched out by a Leghorn hen, for we make use of it for many different emergencies, such as catching a chick or chickens that have "sticktights" or "sorehead," shutting up a sitting hen so other hens can not intrude, penning up a sitting hen (so she can't "bite") while you arrange her eggs or nest, and for various other purposes;* but it answered the purpose most admirably with my "lone duck." When I gave him his bread and milk and some water where he could satisfy his vigorous appetite in peace, while a "howling rabble" surrounded and climbed over his stout barricade, it reminded me vividly of the words of that beautiful and comforting passage in the 23d Psalm: "Thou preparest a table before me in the presence of mine enemies," etc.; and also of the promise, "Thou wilt keep him in perfect peace whose mind is stayed on thee." Dear reader, it just now occurs to me that this is not *altogether* a chicken story nor even a duck story, and I am going to switch off just a little to ask you if this Bible promise is indeed true, as I have held it up before you? Does the great Father ever place a shield or screen around us so we can actually "sit down" in quietness and peace

while the ungodly are leaving no stone unturned to misrepresent and defeat us? I am sure he does. If we fail to find that haven of peace and security when we need it so much, the fault is ours and not that of the great Father who loves us, and loves to have us come to him when weary and overburdened. Read once more the inspiring and comforting words I copied from the *Sunday School Times* on page 30, Jan. 1.

Much is said about hens' nests that are vermin-proof, or nests made of metal so that not only can vermin find no hiding-place, but the whole nest-box may be most effectually "fumigated" by simply lighting a match and setting the nesting material on fire. Such a nest I have figured below, and every *bee-keeper*, at least, can usually find such a nest-box on his own premises without costing him a cent.

Cut out half of one end, as shown in the picture; turn down the flap for a slanting doorstep, and you have a nest that will hold a hen and chickens at night safe from all prowlers, if you just fasten a bit of inch-mesh netting over the open front. As the five-gallon can is air-tight, you will have to close it with netting, especially in warm weather, to give the hen and her brood plenty of air. And this reminds me that, up to this date, Jan. 20, we have not seen an insect nor disease of any sort on any fowl on our premises, and I can almost say we have not seen a housefly. Very likely the latter is because Mrs. Root is so extremely careful not to leave anything outside or inside that can bait the flies and cause them to "hang around" our premises. Truly, prevention *is* better than cure. The last of the two pictures shows the tin-can nest occupied with a hen and her ducklings. She has gone in for the night; but a couple of the youngsters seem to be

Hen's nest and "all-metal" coop for hen and chicks.

*When a hen steals a nest out in the open, and wants to sit, I just set this over her as I go around the last thing at night, and leave her thus shut up and protected until I gather the eggs next day, when it is removed to let her out for necessary refreshment.

J. F. Kight, Southport, Ind., who has successfully combined bee-keeping and squab-raising.

tardy about "getting to bed." They probably want to make just "one more" visit to the feed-dish and little drinking-fountain.

BEE-KEEPING AND SQUAB-RAISING COMBINED.

BY J. F. KIGHT.

As the good old farmer used to say, "I have just laid my crap by." Well, I have just now (Nov. 24) laid my bees by until next April. I have the hives side by side

standing on planks 6 inches off the ground, with leaves under and all over them, a foot deep. They are well covered, and shielded from the west and north winds; yet I am a little afraid I shall lose a few. Last season was the hardest known for bees in this part of the State for many years. They got no honey during July, August, and September, and only a little in October from the white aster. During July and August I fed my 13 colonies a barrel of the best granulated sugar, and yet they did not seem extra heavy when I put them away. Only a few around Indi-

Bees and chickens in the same back lot, Detroit, Mich.

anapolis fed their bees, and I predict there will be more dead bees in this county next spring than have ever been known to die in any one winter. In fact, I now know of several colonies already dead, whose owners would not feed. If mine don't all die I expect to pick up a lot of empty combs in the spring.

I am combining the pigeon business with my little apiary. I keep both as a diversion from my regular business, and have a competent man to assist me.

While my bees are sleeping, my pigeons are making me nice money in the way of squabs and breeders. I have just sent a \$175 order to California, so I can not see why the bee and pigeon business will not go together nicely.

Southport, Ind., Nov. 24.

BEE-KEEPING AND POULTRY-RAISING IN A CITY.

BY L. LIST.

The regular readers of GLEANINGS need not be told that bees may be successfully kept in the city. They have often read about it, and some have tried it themselves. There are two points of interest, however, in the accompanying picture. In the first place, it shows that bees and poultry may well go together. One of the regular contributors of GLEANINGS recently stated that his Rhode Island Reds proved to be a nuisance

in the bee-yard. Our White Leghorns never molested the bees in any way, but, on the contrary, treated them with marked respect.

Another fact worth mentioning in regard to the photograph is this: Our bees stand within six inches of our church school, which is attended by over 200 children. There has never been the slightest complaint. There are no windows on the south side of the building, and the bees have their flight in that direction. Even if there were windows, I would not be afraid of trouble, because bees are not nearly as vindictive as commonly supposed.

For four years this apiary has been run for extracted honey, and there has not been a single swarm during this time. Plenty of super-room and bottom ventilation kept back the swarming fever. I may add that this photo was taken in the prosperous season of 1910, and not in the poor one of 1911. You will notice that most of the supers are of the shallow kind; and I would advise the novice who is keeping just a few bees and runs for extracted honey to give them a fair trial. I have followed the advice of the gentleman from Texas, Mr. L. H. Scholl, and have never regretted it. The deep supers may be better for the owner of many colonies, because a given amount of honey may be more quickly extracted; but for the man with few colonies the shallow ones are ideal, because they are more easily handled, and do away with the heavy strain on the back.

Detroit, Mich.

Bert H. Masters in his bee-yard at Edison, Ohio. Mr. Masters now has winter cases on all his hives, which, he leaves on all summer.

BEES, CHICKENS, AND DUCKS GO WELL TOGETHER.

BY BERT H. MASTERS.

In my experiment with chickens, ducks, and bees, I find that success depends largely upon the amount of care taken. I have always been successful; and, since I can not supply our regular trade with honey, eggs, and poultry, I am arranging this year to increase my apiary to 75 or 100 colonies, and to double my poultry business. My intention is to keep only the best stock.

My two boys are wonderfully interested in GLEANINGS, and are storing away in their minds every thing pertaining to bees and poultry that they can get hold of. I intend to give them full charge of the yards this year to try them out.

The boys insist that I mention a little egg-basket which has been in daily use for a period of 38 years. It belonged to their great-great-grandparents, and it holds six dozen eggs. We have just laid it aside to be kept as a relic. It has averaged three trips to market per week for 38 years. If you take your pencil and figure this out, you will be surprised at the number of eggs that this basket has carried. I do not know the average price during all this time, but I believe it has been about 15 cts.

I have discovered a great remedy for millers and moths, and I have been much interested in watching the practical demonstrations of my discovery. I put my eighty Indian Runner ducks in my bee-yard one evening when the millers were quite bad, and the ducks were victors in a very short time. I am confident that they prevented

Some of Bert H. Master's chickens at Edison, Ohio. He finds that chickens, ducks, and bees go well together.

the millers from getting the upper hand of several weak colonies.

I winter my colonies on the summer stands, but I use winter cases packed with shavings. I do not remove these cases now, but leave them on all summer, as I have

found this advisable on account of the sudden changes of weather which we have. When preparing for winter, I cut and fit several thicknesses of building-paper and place them over the top of the hive-cover.

Edison, Ohio.

SKUNK CAUGHT AFTER HE HAD KILLED 16 CHICKENS.

BY W. A. PRYAL.

A couple of years ago some skunks began nocturnal visits to my chicken-yard. It was in the fall of 1910 (in September, I think) that I noticed that the young roosting chickens in one of the poultry-houses seemed disinclined to take to their roosts when night came on. They seemed to prefer to go into the house with the older stock or else take to the tall trees. Then, a few days later, my man George heard a commotion in the chicken-yard one night, and on investigating the cause of the disturbance he found a skunk trying to make his exit from the yard through the meshes of the wire netting. Not wishing to attack the animal, without a suitable weapon, the

man returned to his room to get his shotgun. On his return, a minute or so later, the skunk was gone. The rascal had already killed a good-sized young chicken, and would have carried it off, but he could not get it through the fence.

Every night after this, ladders were removed so that skunks could not climb to the roosts, and the younger chickens in

A skunk caught in a steel trap, and some of his victims of the night before.

coops near the house were carefully inclosed. However, one night one of the coops was not as diligently looked after as it should have been, for the door was left a little apart, and through the opening a skunk made its way. What a slaughter of innocents there was that night! There were sixteen well-grown young chickens and their mother in the enclosure that night; and of the lot, fourteen young ones were found dead in the morning. One had been caught by the mauler, but escaped with a small cut on the back of its head. All those killed had been bitten on the back of the head at the base of the brain.

Such slaughter roused my dander. The Irish in me was up, and I was bent on getting that skunk or "bust." And I got him! And it is with much pride and delight that I herewith present a picture of the dead skunk and some of the fine chickens he so ruthlessly murdered, together with several of the traps that were set that night to capture him. The trap that "did the work" was a small steel-jaw trap that was set in the center of the large coop in which the chickens had been killed the night previous. About a foot above the trap one of the dead chickens was suspended by a wire. I believed that the skunk would return again to kill more chickens or else claim his prey, and I gave him this opportunity to claim the one that was hung up in so tantalizing a way, and he was bent on getting it. He danced into the trap; the trigger was sprung, and the skunk firmly held by one leg until he was duly killed in the morning by George.

Since then I have lost no more young chickens, that I am aware of, by skunks, though we have set traps for them now and then. Only one has since been caught, and that was a few weeks ago when one was secured in the large box trap that was set to catch rats. And here I might remark that this trap is the best rat-catcher I ever knew; it gets the rats when all the wire and other traps fail. I suppose it is such an innocent-looking old thing that the most wary old rat is thrown off his guard, and walks into the box to nibble at the bait, which is usually a piece of old raw or decayed meat.

Oakland, Cal.

CAUGHT IN THE ACT.

A "Tame" Skunk Eats Bees.

BY J. D. YANCEY.

One day last summer, late in the afternoon, my sister being out in the apiary, called to me to come to the aid of my bees before they were all devoured. Of course I came on the double-quick, and you may imagine my surprise as I passed around the

corner of the kitchen to behold a skunk, almost as big as a badger, near the entrance of the second hive, calmly eating bees. I was so angered at his cool impudence that if I had had a club in my hands, I would have—on the spur of the moment—"lamed him one" good and proper. But on second thought I knew this would not be the best policy so near the dwelling.

While I stood watching him he finished devouring the first bee; and, running up on the alighting-board, seized another from the crowded entrance, rolled it under his front paws on the alighting-board, then backed off to a safe distance and proceeded to eat it, beginning at the head and finishing it to the tip, sting and all. The skunk seems capable of running backward with as much celerity as forward; and his movements as he runs up and grabs a bee, smashes it with his fore feet and then backs off, are made so rapidly as to seem almost automatic in action.

The bees seemed to be angered very much by his murderous assaults, but for some reason they would not attack him; in fact, in a few minutes they became so intimidated that they every one disappeared into the hive. Mr. Skunk, however, had evidently robbed bee-hives before, for he knew exactly how to proceed. Running up again to the entrance, he drummed on the floor of the hive making a noise much as you would by drumming lightly on a hive with your knuckles. This caused two or three bees to dart out of the hive, and one of them was promptly seized. In his eagerness, however, he lowered his head too near the business end of the bee and received the sting full in the end of the nose. Well, Mr. Skunk was certainly surprised, and he dropped that bee just as if it had been red-hot. He seemed to think the scraping motion was the proper scheme for removing stings, for he backed off about ten feet as fast as he could go, scraping his nose on the ground and sneezing as if he had taken a whiff from a pepper-box.

May be you think that gave him enough; but he seemed to be following the advice of those bee-keepers who tell you to scrape out the sting and forget about it at once and it will cease hurting promptly.

Being a little leary about tackling the same hive again, he next came to the hive near which I was standing and caught a couple of bees, stopping to eat them so near me that I could have kicked him—had I been so minded, of course. Once he ceased operations, and, sitting up on his hind feet, gave me an impudent stare, as much as to say, "If you don't like it, help yourself."

I suppose he did not like the flavor of the bees from this last hive, for he soon went back to scratching in the entrance of the first; but the bees appeared to be thoroughly cowed, for none of them would venture forth, and after a few more futile efforts his Skunkship took himself off into the fast-gathering darkness, and I saw him no more.

Bridgeport, Wash.

BEES AND POULTRY ON A BACK LOT IN A CITY.

BY L. J. GRIFFEN.

My experience in bee-keeping and chickens is more of a "has been" than a "present" experience; but for a number of years I took off about 400 pounds of "fancy" honey and raised about 300 fancy chickens (White Wyandottes) on a city lot one hundred feet square.

My occupation is that of customs examiner (deputy collector and inspector), and the last four years my work has increased so much that I have had to give up most of my bees and chickens, and I miss the monster that they used to bring in.

I have always been very fond of honey, and was seldom able to get any that was especially good; so about ten years ago I began to study bees. After six months I dreamed of bees every time I went to sleep; then I bought two colonies in Danzenbaker hives from a friend who was planning to leave town. They were hybrids. I sent to two different queen-breeders for a queen from each, and divided the two hybrid colonies, making four. One queen was excellent, and soon had her hive full of brood. The other was no good—could barely fill five frames, and later I killed her. The first year I secured about 140 pounds of honey, of which two-thirds was fancy.

The same year I commenced to study chickens; and before spring arrived I was dreaming of chickens. I bought an incubator and two brooders, and 220 White Wyandotte eggs (I was the pioneer White Wyandotte chicken-man in Bridgeport or vicinity).

I had excellent luck (?), and hatched 153 chickens. When they were about three weeks old they suddenly commenced to die off. I finally found that the trouble was moldy chick-feed, tiny particles of green mold being mixed with the fine grains. I threw the rest away and got some that was fresh. I seldom buy chick-feed now, for several reasons—first, it is almost impossible to buy fresh chick-feed early in the season; and old chick-feed of the previous year is very likely to cause bowel trouble; second, if scattered on the ground, all particles that become covered will turn moldy, and then when uncovered will be eaten, resulting in a dead chicken a week or two later; third, little chickens three days old will eat wheat and thrive on it.

I figured out that a mash composed of corn meal three parts, bran one part, middlings one part, and beef scrap one part, would be about right. I think so yet, after nearly ten years' trial, although when I find it hard to get good middlings I use corn meal two parts, bran two parts, and beef scrap one part, substituting one of bran for the middlings, and dropping one of corn meal.

Out of my hatch of 153 I raised 116. I saved the best for breeders, and killed the cull pullets for broilers, and the cull cockerels

were made into capons, which I learned to do by following directions in the book that came with the caponizing set.

In performing the operation at first one bled to death, which we ate as a broiler, and I cut the lung of one a trifle, and he had wind puff. On tapping him with a pen-knife he recovered. I made one change. The directions said, use carbolic acid in the water; but I used bichloride of mercury, one to one thousand—7 grains to 1 pt. of water. Those capons made my reputation for delicious chickens.

About three or four weeks before killing I would shut four in a coop with slatted front and bottom two feet high, two feet long, and eighteen inches deep. I had four of the coops in a row about the nests. There was a dropping-board below the coops so that it could be taken out and cleaned, and a shelf in front to hold the feed and water. They were fed mash entirely. When there are four in a pen, one seeing another eating, he thinks he must eat also. The second day before killing I gave some charcoal, and the last day nothing at all. My pullets that were hatched about April 20, commenced to lay about Oct. 7.

The same year I had four colonies of bees. The previous fall I had killed the poor queen, and had given them a frame of bees from my best queen from which they had raised a good queen. I fed in March and April about two dollars' worth of sugar and got about fifteen to twenty sections from each colony of apple-blossom honey with a little dandelion mixed with it. We have very few dandelions in this section.

During the summer flow my two hybrid colonies put up a solid super of chestnut honey, and my two Italian colonies a solid super of sumac honey, both flows occurring at the same time. Chestnut honey is greenish yellow, rather dark, and of poor flavor. Since then the chestnut-trees have all been cut down, for which I am thankful.

Before leaving on my vacation in September I looked at the bees and found very little honey. On my return there was a sour smell, and I immediately concluded the bees were dead, and the nectar and brood soured; so I opened the hives and was surprised to find each super crammed with honey—mixed goldenrod and wild aster. I put another super on each colony, and they also were filled with honey. One season the bees stored wild-aster honey in the super as late as November 7.

The following spring I started early with my incubator, hatching on Washington's birthday. I placed one of the brooders in the cellar, put a glass top on the two compartments, and kept the chickens in the cellar for three weeks. By that time they needed damp ground (the cellar has a cement floor). I made pens 6×12 feet across the front of the lot next door, 50×100 ft. (it was poor sandy soil on which I could make nothing grow). The top of the pens was made so that it could be rolled back for the purpose of digging the soil. First rye, then

oats, and finally wheat, were planted, as there is nothing better for young chickens than sprouted grains.

I kept the incubator going, hatching about once a month. The pullets which had hatched on Washington's birthday gave me the first egg on July 2—four months and ten days. These had been put in a sort of colony house, so that I had at one end laying pullets; and at the other, chickens only two weeks old.

After three years the ground became so rich and full of poison for chickens that I had to move the pens. I planted corn on that ground for three years in succession without any further fertilizing, and by that time I could use it for chickens again. I find that corn is the best renovator of the soil.

On clear Sundays at least 500 people used to come to see the chickens, the pens being next to the street. The fame of those white chickens spread far and wide.

I feed only whole grains, and have, at present, movable coops so that they can be rolled or carried to fresh locations, about six weeks at first, and then about every two weeks after that. I always expect my pullets to lay at the end of five and a half months. I attribute the early laying to the large amount of beef scrap that I feed.

In 1903 I hatched a pullet that I leg-banded as number 8 (I started leg-banding that year). She proved to be a wonder, laying 264 eggs in one year. In 1907 I had her in a pen with four of her daughters, and the five laid 88 eggs in 20 days.

My third year with the bees was even better than before. They had increased to six colonies, and gave me about four hundred and fifty pounds of honey, most of which was fancy. All No. 2 honey is cut out and given to the neighbors. I have had complaints but once, and that was because a neighbor was sore about another matter.

In the fall of 1904 I discovered that my best hive was rotten with foul brood. I found that bee-keeping in the suburbs of Bridgeport and for a distance of ten miles each way was steadily decreasing because of foul brood. I then started the agitation which finally resulted in our present foul-brood law, which, while better than nothing, is far from ideal.

Bridgeport, Ct.

POULTRY AND BEES.

They Go well Together if the Man "Stays by the Job."

BY H. E. ZECH.

As a breeder of Silver Comb White Leghorn hens and Indian Runner ducks, and as a bee-keeper and farmer, I wish to give my experience, with some statistics, regarding poultry and bees, for the benefit of the GLEANINGS family.

I started bee-keeping in the spring of 1906 by buying four colonies in movable-frame hives of no standard make, and the

same season I got about 150 lbs. of fine white honey, some in sections, some chunk. This looked good, so I increased by buying ten-frame Langstroth hives and Italian queens, and now have 17 colonies and about \$125 worth of hives and fixtures, and \$21.44 to the credit of the bees, not taking into account the honey used and given away.

During 1911 we kept from 150 to 225 hens, which returned to us \$635.63. No eggs were sold for more than 40 cts. a dozen, no account was taken of eggs and poultry used, and I have no exact account of all the feed consumed; but the mash, beef scrap, shell, grit, and charcoal, fed to both young and old stock, amounted to \$99.79. I use simple home-made self-feed hoppers arranged with a 2½-inch-wide second or trough to catch that which crumbs from the hens' mouths, and which would otherwise be lost. By arranging the troughs right as to height, a nice slanting cover can be hinged to the front of the feeder to keep rats out at night, or to shut the hens away from the mash a part of the day at certain seasons. By keeping the mash accessible to the stock, practically no damage is done to the growing crops close by the buildings. I should judge that the mash, etc., cover at least two-fifths of the feeding expense. For raising chickens, I use Prairie State and Cypher's adaptable hovers attached to 7 x 10 portable houses, which are used in winter for laying hens. Records of three flocks show that I raised 94 per cent, cockerels crowing when 29 days old, and pullets laying when 4 months and 13 days old.

I breed the English (or penciled) variety of the Indian Runner duck, of which I raised 97 per cent. They hatched June 6; and up to date, Jan. 18, they have given me 234 *white-shelled* eggs. Notice I said *shell-ed*, as some duck eggs sometimes have a dull dirty gloss which, when immersed in water, may be slippery or mucus-like, and which must be washed off in order to have the really beautiful white egg. See what A. I. Root says on p. 447, July 15. I do not expect that they will continue to lay, as we have been having very cold weather for three weeks. Before that, the weather was good for fall laying.

As to poultry-raising and bee-keeping going together, I will say that, so far as the most important factor, the man, is concerned, they agree well, for both pursuits require patience, persistence, and some enthusiasm. On nothing does success depend more than on the man who is among the bees and hens, and who cares for them. It is important that a beginner start in a small way with good stock, and increase as he can profitably handle more, all the time realizing that it is the *man* which is on trial, and not the bee nor poultry business, as both have been tried. And do not take up another branch if you have enough already. Do not go into any business deeper than it will allow you time enough to do some good sound common-sense thinking; for a lack of this is the cause of most failure, and will

lead one into the habit of laying it to poor luck when things go wrong, while in reality there is no such thing—only your failure to attend to some essential.

Seven Valleys, Pa.

A BEE-KEEPER'S REMINISCENCE.

BY WM. BEUCUS.

Years ago, when I first began my apicultural career and knew all about bees, I said one morning to my wife, "My dear, we're going to stay home this forenoon. The bees won't swarm to-day."

I began to busy myself by turning my attention to the lawn, humming at times little ditties, and breaking out vigorously at times in a deep bass voice which one of our friends heartlessly said sounded like a saw-mill in distress. In the midst of one of these outbreaks of feeling I was brought back to the reality of every-day life by the exclamation, "The bees are swarming!"

Upon reaching the bee-yard I found a swarm circling around without the slightest regard for any one's feelings. The bees finally met in convention on a huge limb high up in an immense oak. My heart sank within me; but hope returned, and I got the ladder. I made up my mind to sweep the senate, secure a majority in the house, shear the committee on rules of its power, and to make some innovations that would teach those bees where they were going to get off. I tied one end of a rope to my ankle and the other end to a basket, and mounted the ladder, scaling the trunk above the ladder like a monkey.

The campaign was nicely planned, and every thing should have terminated well, but "the best-laid plans of mice and men gang aft a-gley," as has been said by the poet.

I reached the bees safely, and found that they were full-blooded hybrids. Two or three bees faced about and stared in an unmannerly way that is always disconcerting to a sensitive nature; but I proceeded to pull up the basket in a calm and nonchalant way, as if the danger were a pastime, while my wife looked on proudly from below. I then proceeded to scrape off the bees with unerring hand. It was then that those hybrids made an exhibition of themselves that was entirely out of place. One, with foul intent, harpooned me on the hand; another went up my sleeve; but when they advanced in solid phalanx and made a flank movement, pouring in a volley of poisoned arrows through my thin denim trousers, I became disgusted and made up my mind that I wouldn't have bees that acted in that disgraceful way. I began to retire then.

"Don't come too fast," said my wife. I assured her that I couldn't. I was taking full advantage of gravity, although it was not intentional. Fortunately the rope, which was attached to my ankle, was fastened to a limb of the tree, and thus was prevented the disfiguring of the lawn. After a long interval (at least so it seemed to me),

my wife, who had gone after a knife, relieved me of the monotony of swinging, suspended by one leg, like a pendulum, fighting valiantly, and with perfect presence of mind, the bees which had taken advantage of the absence of a bee-veil, and were, without feeling, burrowing in my hair and clinging tenaciously to my face and neck. Even after I had gone into the house, had cared for the stings, and had fallen asleep, my slumber was disturbed by the eternal buzz, buzz, buzz of swarming bees.

Cadott, Wis.

FLIES AND MAGGOTS FOR POULTRY.

BY THOMAS DEWEES.

As an interested reader of GLEANINGS I can not refrain from having a part in the discussion concerning the use of stale meat, maggots, and the like as a food for poultry. That chickens may be used as scavengers is altogether correct; as, when supplied with such or allowed access thereto, they will eat all sorts of filth and corruption. But if we are going to use them for this purpose let us, for the time being at least, discard them as a food for our own bodies. That the quality and quantity of the blood is dependent on the amount and character of the food, is a fact well understood; also that it is from this life-giving current that every fiber and tissue of the animal body derives its strength and is built up.

Understanding this, I have about the same use for eggs and flesh of fowls laden with such loathsome germs as those must be that have been subsisting on putrid flesh and worms that are a product of the same, or, in fact, any decomposing or fermenting substance.

Now for an intelligent solution of this problem, I want to invite readers of GLEANINGS to make the following test: Take from your flocks a thrifty fowl and place it in clean comfortable quarters, and supply it with clean and suitable food, with fresh pure water, for a period of from eight to ten days; then kill and prepare it for the table; then in like manner prepare one that has been allowed to run at large, or perhaps fed as indicated. Note the difference in flavor, and decide for yourselves. Also the same difference may be observed in the eggs from hens receiving nothing but clean pure feed.

Now as to the destruction of flies, if I am not mistaken the fly that deposits its eggs on the flesh and decaying animal matter is a particular kind of green fly, often called the blow-fly; and while it is sometimes an annoyance it is one of the provisions of an allwise Creator for the quick disposal of these decomposing and offensive bodies that poison and pollute the air we breathe. If I am right, the more common fly that frequents our houses deposits its eggs elsewhere, very largely in manure-heaps, and kindred places where there may be a little extra warmth.

Barnesville, O.

Heads of Grain from Different Fields

A Form for Holding a Shallow Frame when Putting in Foundation.

I have made and used for the last few years a contrivance to assist me in putting the foundation in shallow extracting-frames.

To make one, take a piece of board 1 x 4 x 19 in. for a base. Nail firmly to it, in the center, a board

1 x 5 1/4 inches, and 16 1/2 long. This should not be as wide as the frame by about 1/2 inch. Half an inch from the base nail a 3/8 in. piece 2 in. wide, 16 1/2 long, for a guide. The frame will then just slide under it. Next make a button an inch wide and 2 long, just as you would to fasten a door, and screw it on top of the upright in the center, as shown in the illustration.

To use the device, slide the frame under the guide against the upright, and turn the button so that it will be held firmly. The foundation will drop naturally into the groove, straight and true. It will not warp, nor lean to one side. Fasten it with hot wax in the ordinary way.

Morgan, Texas. T. J. FORD.
[For full sheets we can see that this form would be quite a convenience. The illustration shows only a starter.—Ed.]

Cold Weather for California.

Owing to the early frosts which killed all the late bloom, my bees did not go into the winter in very good order. I had to double up some and to feed others to pull them through. We of the northern part of the State have had very little rain, but a great deal of cold weather for this country. It was down to 14 above zero—the coldest for a great many years. Jan. 1 we had a five-inch snow followed by warm rains with the thermometer ranging from 34 to 70. The bees are now (Jan. 15) bringing in pollen from alder, which will start brood-rearing that will be of great value in building up for the main harvest, which will come here in April and May.

E. S. BARTELL.
Cottonwood, Cal.

Case's Nucleus-frame and Top-bar.

Fig. 1 shows my nucleus-frame, 5 1/2 x 8 inches, made of 3/8 x 3/8 stuff. Fig. 2 shows a top-bar 7 inches long, of 3/8 x 3/8 stuff, and manner of adjusting the same. After the top-bar is in position I turn it to the right, Fig. 3, until it is parallel with the top of the frame, and the tins hold it firmly, Fig. 4. The holder is made of very heavy tin, 3/8 wide. The ends are bent 3/8 inch from the ends, and are 3/8 inch apart—just right to hold two 3/8 pieces tight together. The tins are nailed on the edge of the top-bar, 1 1/2 in. from each end. The end of the tin on top of the top-bar is bent at right angles—the bottom end not quite so much, but so it slips under the top of the frame easily. The end that rests on top of the top-bar holds the tin firmly. When nailing on the

tins a spare top-bar should be used to fill up the tin to get the tin nailed just right. The tins may be bent at a greater or less angle to accommodate the frame-tops scant or full thickness.

I use these frames hung in the hives with 3/8 x 3/8 rabbets, just as brood-frames are used. The top-bars can be put on or taken off very quickly when once the knack is learned.

Three tins nailed on one side of the top-bar of an ordinary brood-frame hold the nucleus-frames very nicely; but as these top-bars are thicker, different-sized tins are required. They must project 3/8 inch below.

It seems to me the above arrangement is the best also for reversible frames. They could be used in ordinary hives, reversed with little trouble, and used anywhere. Four to each frame, 3/8 or 1 inch

wide, would, perhaps, be about right—Fig. 6.

Port Orange, Fla., Jan. 9.

J. B. CASE.

Why Not Breed Bees with Longer Tongues?

I note in the short time I have been interested in bees that a long-tongued bee would be of incalculable benefit to the bee-keeper. Now, we know that Burbank has done wonders in creating new kinds of fruits, flowers, etc. These fruits and flowers, as I understand it, are something the world has never known before, and yet they are produced by understanding the laws of nature with regard to interbreeding and crossing.

Perhaps by selection for a number of years one might be able to get something bordering on a long-tongued bee, and then, again, he might not; and at the same time the new species might at any time revert and have shorter tongues than the original stock.

Pittsburg, Pa., Jan. 24.

ARTHUR CRAMER.

[Something like ten years ago we experimented along this line considerably. We found the difficulty, however, lay right here: We could not control the male parentage of the queen. If that were possible we might practice inbreeding.

There were several queen-breeders in the coun-

try who tried to lengthen out the tongue-reach of the bees; but we found that we had to depend almost entirely on "sports." We had one queen whose bees gave a tongue-reach of .23 of an inch, while the average of black bees runs only .16 to .17 of an inch.

Later, efforts were made to construct a cage 30 ft. high and 30 ft. square in which the drones and the queens might meet in the air; but this did not

prove to be any great success. So we are practically right back where we were years ago. If you can work out any scheme we shall be glad to hear from you further.—ED.]

Profit from Forty Chickens.

My bees will have to hustle to beat my hens. Last January I had 56 hens; last June 35, with an average for the first six months of about 45. I now have 32, making an average for the year of about 40 birds. The last of November I was \$71.76 ahead of expenses, and had raised 23 pullets, which have laid 149 eggs this month. This is not taking into consideration the value of these pullets, although the cost of raising them has been charged to the hens.

Eggs from hens from Jan. 1 to date, Dec. 25, \$62.18; eggs from hens and pullets, \$63.80. Considering the value of pullets and what eggs I get this month, the profit from forty birds will be about \$100. The only care required is at night and in the morning, before and after 6, with the exception of watering them during the day, which my wife does, and only lately have I fed them more than once each day.

Brewer, Me., Dec. 25.

E. H. BISSELL.

Winter Treatment of Foul Brood.

I sent a sample of brood from one of my neighbors to Dr. E. F. Phillips, and found it to be affected with American foul brood. I do not know whether it would be best merely to clean our hives up and let them go, or to send for an inspector and get rid of the box hives entirely. In the first place, we do not know where the trouble came from, as there have been no bees sent in nor queens bought or sold. I have about 15 colonies, and my neighbor has one. They are all together in my cellar. Will the disease spread in the cellar?

Vassar, Mich., Jan. 8.

J. W. ROWLAND.

[There is not much you can do in the way of handling foul brood during midwinter except to scald out or burn out hives that are empty, and melt up all combs of which you have any doubt. If the disease during the past summer got any kind of hold upon your bees or those of your neighbor, we would advise you to melt up all the empty combs you have, as a matter of precaution, boil the frames, put in foundation, and start over again next season. While some authorities think it is not necessary to scald out or burn out the inside of the hives, we believe it is very much safer to do so. This is a recommendation of Dr. E. F. Phillips, of the Bureau of Entomology, Washington, and many of the inspectors of the country.]

Foul brood will not spread in the cellar nor during cold weather, as it is only when brood-rearing is going on that it can do so. You probably will not have any trouble again until next spring when the weather warms up and the queen begins to lay.

We are not certain; but it is our opinion that the foul-brood law of Michigan requires the transferring of all colonies in box hives. It would be well for you to call for the inspector, and we therefore advise you to write to R. L. Taylor, Lapeer, Mich.—ED.]

Chickens Eating Bees.

Regarding Mr. Scholl's article, "When Chickens are a Nuisance," p. 486, Aug. 15, when a chicken begins to eat bees, nothing will ever break it off. It does not care for any other food, and rapidly loses flesh. Old fowls rapidly follow the example after seeing the chickens eating bees; but they rarely start of their own accord. I have seen a chicken completely covered with bees trying to sting it as it was catching its meal right on the alighting-board. It just stood back, picked them all off, and started on some more. Tiny chickens never start on bees; but big chickens, fit to eat, do. Such chickens can never be caught by the usual means. Grain is no temptation to them. We either shoot them or catch them somehow, and give them to some of our neighbors who do not keep bees. To remedy this nuisance we have raised our hives about 18 inches from the ground. Since then we have had very few cases. I should not like to be without fowls in the bee-yard. They seem to keep ants and other insects down. Turkeys and ducks never eat bees; and if a small turkey swallows a bee by mistake it invariably dies in great agony, turning and twisting its neck as if all the pain were there.

STEPHEN ANTHONY.

Waitete, Amodeo Bay, Auckland, N. Z., Sept. 25.

Don't Put All Your Eggs in One Basket.

I believe there is nothing that fits in better with bee-keeping than poultry. Poultry can be attended to early in the morning and again in the evening, while bees should not be disturbed before 9 A.M., and not much later than 4 P.M.

Another argument in favor of the combination is that both bee-keeping and poultry-raising can be carried on in a small area. Besides, a man who makes a success of bee-keeping should do well at poultry-keeping, for both occupations require close attention to details. Then, too, where there is a city market near, the product of both the bee and the hen can be sold at the same time.

I don't like to disagree with such eminent men as G. M. Doolittle, the late E. W. Alexander, and W. Z. Hutchinson; but regarding the slogan, "Keep more bees," I must plead *locality*, and fall back on the old adage, "Don't put all your eggs in one basket." In fact, I have known them to fit in so well together that a deserted hen egg hatched into a fine healthy chicken over a strong colony of bees. However, I didn't give it to the bees to mother.

BLACK CHICKS STUNG WHILE WHITE ONES ARE UNHURT.

Just here let me give warning not to allow the poultry to run among the hives, as I lost a fine flock of chickens last spring, which were stung to death by the bees. One sting is fatal to a young chicken. I lost 30 out of one hatch, and, strange to say, the black ones were attacked while the white chicks were unmolested. Bees certainly draw the color line, so bee-keepers will find it to their advantage to keep white hens.

Slate River, Ont., Jan. 14. JAMES M. MUNRO.

[There has been quite a stir in the newspapers, several times, over the possibility of hatching chickens on a large scale in supers over colonies of bees; but except in hot summer weather we believe the plan is not successful. And even then, incubators are cheaper and better.—ED.]

The Trickey Method of Treating Foul Brood.

In treatment of foul brood, p. 710, 1911, 1, what is done with combs first removed?

2. At what time of day should this be done?

3. Would the result be the same if the old hive were moved in the middle of the day, then brushed at night, the new hive being first supplied with a small piece of unsealed or sealed brood?

Bradshaw, Neb., Jan. 8.

C. B. PALMER.

[1. They should be extracted if they contain honey, and melted up. Frames should be boiled before being put back in the hive with foundation.]

2. Usually in the middle of the day when bees are flying the thickest. This will avoid any disturbance, for the bees in the field will return to the new hive.

3. Not quite; because in so short a time the bees would hardly have gotten over their first disturbance.—ED.]

One-fourth of the Potatoes in Northern Michigan Frozen.

It is pretty cold here now. I believe that one-fourth, if not more, of the potatoes through Northern Michigan have been frozen during the past two weeks.

Our bees are wintering finely, however, for I can keep the temperature right during a cold winter better than I can during a warm one or one where the weather is changing all the time. The bees are so quiet that I can hold a candle almost close enough to burn them, and not even a buzz comes from them.

Pioneer, Mich., Jan. 20. ELMER HUTCHINSON.

[That certainly indicates that all conditions are normal, and that the bees should come out strong.—ED.]

Brood in Caucasian Colony in January.

Last September I introduced a Caucasian queen to a small colony. I gave them three frames of honey, and left them for the winter. We had very little rain here last year, and it has been warm and cold in succession. Yesterday, Jan. 14, the temperature was 72°. On looking into the Caucasian hive I found a patch of brood and eggs the size of my hand on both sides of a frame. I was unable to find a sign of an egg nor of any brood in my Italian colonies.

Highland, Cal.

J. R. LAFOLLETTE.

Our Homes

A. I. Root.

Therefore the ungodly shall not stand in the judgment, nor sinners in the congregation of the righteous. For the Lord knoweth the way of the righteous; but the way of the ungodly shall perish.—PSALM 1:5, 6.

With all my busy cares (at least they seem to me of enough importance to call them "cares") I try to read the dailies enough to keep pace with at least something of what is going on in the world; and I confess that many things are coming to pass that make me feel the need of some such comforting promise as the one at the head of this talk to-day. What troubles me most is that God evidently expects his chosen followers to help bring about the time when the sinner shall *not* stand in the congregation of the righteous. Letting criminals go scot free, or letting them off with a punishment not one-tenth of what they deserve, is what worries me most; and as an illustration of the tendency of the times let me quote from the *Chicago Advance* of Dec. 28:

A WIDOW'S CRY.

"My God! Why is there law, any way? There is no use of expecting any thing from the law. The guilty ones are allowed to escape."

This was the heart-broken cry of the young widow of a man murdered by an infamous gang of Chicago toughs when she heard that their execution had been postponed and might not occur at all.

The police are quoted as saying that the crime was one of the most brutal and atrocious ever committed in the city or county. The young man was a gardener, and it was necessary for him to come to the city in the early hours of the morning. It was a time when half a dozen young robbers were looking for a victim. They met him in the road with clubs and guns. He begged them to take his goods but to spare his life for the sake of his young wife and that of his baby, two months old, who needed his support and protection. The only answer was a more fiendish assault. They struck him on the head with a fence-rail, and it is reported that they even knocked out his teeth and drove a stick down his throat. Then they left him dying in a ditch and scamped away to make war on other industrious people who happened to have something which they wanted.

Fortunately their identity was discovered and they were captured. One or two of them confessed, and four of the gang were sentenced to be hanged December 22. But in spite of the fact that they so richly deserved it, and that the prevalence of high-handed and bloody crime called for a prompt and effective enforcement of law which would produce more respect for it among the lawless, and more confidence in it among the law-abiding, a movement was made upon the governor of the State to prevent the execution, and it succeeded!

If this movement had been made only by the paid attorneys in the case and the relatives of the murderers it could be passed over; but it had the backing of such influential people as Dr. Hirsch, Miss Jane Addams, Jenkin Lloyd Jones, Professor Charles R. Henderson, and others. Some of these interferers with the mandate of the court seemed to have a rather hazy reason for their meddling, except that they did not want a hanging. As Roosevelt once said in a Chicago address, some people do not feel the pain of the murderer's victim, but do feel intensely the pain which the murderer ought to suffer for his crime. Perhaps this explains in part the action of some of these individuals for blocking the enforcement of law.

But others of the interferers were more explicit. Professor Henderson's reasons, as given by the daily press, include the declaration that "capital punishment is not necessary for any rational, social end." But the great commonwealth of Illinois declares on its statute-books that it is necessary; and it is the part of wisdom to pay more attention to the law than to a professor's theories.

The professor also says that capital punishment tends to increase rather than diminish crime. But the statistics for the crime of murder show that there has been a frightful increase of murder in this country since the decrease in hangings set in. From the year 1887 to 1908, as shown by the statistics of the *Chicago Tribune*, which have commanded wide attention, the murders in this country increased from 1266 to 9000. One year there were more than 10,000. In fifteen years the total number was 133,192, while during the whole four years of our Civil War the number on the Union side who were killed in battle was only 101,000. That is to say, fifteen years of murder in this country cost more lives than the battles to save the Union cost. We are fighting tuberculosis and a lot of other germs; but the worst germ in this country is the murder germ. Once we cured it with the rope; now we are treating it with sugar-coated sentimentality, to university theories, and social-settlement softness. During the last two years there have been 653 homicides in Cook County—Chicago's county—and not a single hanging; and of these homicides more than 300 were "cold-blooded murders." (This information was received direct from the sheriff's office.) In five years there have been no executions in Chicago, the last having occurred December 13, 1906. In Louisville, Ky., a State where the public had the impression that murderers are hanged, there were 47 murders during the year which ended August 1 last, and not a single legal execution.

Last year the total number of homicides in the country was 8975—an increase of nearly 800 as compared with the previous year, and yet there was a decrease of executions. Only 104 persons were put to death by law. In a word, while murder has been increasing so frightfully as to be but little less destructive than war, hanging is nearly played out. In Chicago, where the execution of these brutal murderers was prevented by alleged philanthropists, murder is a continual occurrence, and executions need no longer be feared by the infamous scoundrels who knock early risers on the head or shoot down women in cold blood because the women get excited when a revolver is thrust in their faces and they are ordered to hold up their hands. "The most significant feature of last year's figures for murder," says the *Chicago Tribune's* report, "is the increase of murders committed by thugs, thieves, burglars, and hold-up men." It is this kind of murder which the interferers with law have now made more safe in Chicago. The man who wrote the magazine article entitled "Encouraging Murder" could find great encouragement for another article in this recent performance.

Dr. Andrew White, in his notable discussion of the subject, said, "The murder rate is from ten to twenty times greater in the United States than in Great Britain and other northwestern European countries. In London, with its great population, during the year 1909 there were only 19 cases of murder. Of the murderers, five committed suicide (executed themselves), four were executed, and four were found insane. Compare these figures with Chicago's 300 'cold-blooded murders,' and not an execution! And yet Professor Henderson is quoted as arguing that England has reduced crimes of violence by a reduction of capital punishment. The real fact is that England hangs murderers, and as a result she does not have many to hang.

Many of the readers of GLEANINGS are interested more or less in market-gardening, and know what it is to get up early and sit up late to raise stuff, fighting frost and flood and drouth. Now just think or having the crop grown, and on the way to market, and then being beset by a crowd of toughs from saloons, and being murdered in cold blood, as mentioned above. Although the *Advance* did not touch on the matter I think they will agree with me that this crowd was the direct outcome and *output* of the saloon business. What does Christianity mean, and what does the expression "the land of

the free and the home of the brave" mean if this thing is allowed to go on?

Once more, the McNamara brothers have finally been obliged to confess, and may God be praised for so much; but what would have happened if they had not confessed? When first arrested the elder one said openly he would get free, and gave as a reason that a predecessor in the same line got off because his friends raised \$50,000 to get him off, but that *he* (McNamara) was so much higher up (higher up in what?) his friends would readily raise \$200,000, and they did raise *almost* that amount.

Now, dear friends, please do not rush to the conclusion that I am opposed to organized labor, for in truth I am glad to see people stand together to resist injustice and oppression; but what I vehemently object to is defiance of law, or taking the law into their own hands when it seems slow and ineffective. It is the disregard of law that threatens the ruin of our country.

Just recently the Baptist brotherhood of Cleveland, O., have been trying to have the mayor and chief of the police enforce the law against open saloons on Sunday. These officials, while admitting the law was plain and clear, refused to enforce it, for no other reason, so far as I could gather, than that "the people do not want the law enforced."

At Newark, O., about a year ago, the saloon-keepers did not want the law enforced, and put to death an officer of the law who was trying to enforce it. Just recently the county has voted wet, giving as an excuse that the law could not, or, rather, perhaps *would* not, be enforced if they continued to vote it dry.* How could they expect any temperance law to be enforced when they continued to put into office men who are not in sympathy with either temperance or Christianity? May the Lord be praised for the good and brave men who are here and there getting into office and exposing the graft and bribery and fraud that seem to be turning up almost everywhere. Well, after much pains and time and trouble we do succeed in getting the guilty ones "red handed," for God's sake and for the sake of the honest, faithful, hard workers, let us put aside our foolish scruples and weaknesses, and enforce the law to its *very letter*, until the law really is a "terror to evil doers."

*I clip the following from the Cleveland *Plain Dealer*: "Newark business men are dissatisfied with conditions in this city under the Rose law, and are predicting almost a solid front to change the speakeasy, blind tiger, and kitchen-bar into the regulated saloon." Will some one point out to us where there is, ever was, or ever will be a "regulated saloon"?

POULTRY DEPARTMENT

A. I. ROOT

ANOTHER "GREAT DISCOVERY" FOR THE BENEFIT OF POULTRYDOM.

I am sure our good friend of the *Reliable* will be pleased and entertained by what I have to tell you, even if no one else will. Just listen to what I have run on to.

It is no new thing to have a hen that lays eggs while she cares for a brood of chickens (say three or four weeks old), for, in fact, my strain of White Leghorns was built up from such a mother, as you may remember; but I propose to have a strain of fowls that will go away ahead of this. You will bear in mind that I am trying to get a duck from every one of the three eggs I get daily from my three ducks. Well, my Cyphers incubator holds only about 50 eggs; and as the incubator is needed about 30 days for each hatch, the duck eggs, to use them all, needs a sitting hen (to help out) about every week; therefore I have been waiting anxiously for a sitting hen among my Leghorns, Buttercups, and crosses of the above two breeds. About three weeks ago I found a half-blood hen on the nest while gathering the eggs, and she was still on at dusk. When I gently touched her she showed such determined fight I was almost scared out. She acted as if she were really going to eat me up, in little bits at a time. Now don't forget this, for it is a most important "link" in my "great discovery." I carried her to an empty brooder-house and gave her the orthodox thirteen duck eggs. She stuck to her job

very well, and when the usual seven days were "accomplished" I had another fight with her to permit me to test the eggs. It seems I had never been able to catch her taking refreshment, because she was so exceedingly wary. Now listen, for we are coming to the climax. Instead of thirteen eggs I found *sixteen*. Bear in mind, no other fowl was in the closed building, and, besides, the three extra eggs were of a brownish tint, entirely unlike the duck eggs. (By the way, isn't it funny that, while both breeds lay a white egg, a cross between the two should lay a brown one?) Well, on testing the eggs one of the brown ones showed it was laid at least five days before the testing (a chicken is now breaking its way out of that egg while I write*); the other two had made so little progress we used them for the table. Do you see the point? This hen had really laid three good eggs after she had commenced to sit, and after she had commenced, also, *in real good earnest*, as I happen to know, and there is hardly a question but that a strain of fowls may be developed that will lay eggs, more or less, while they are spending their time sitting

*After finishing the above I went down and took a look at the incubator, and found a big strong chicken clear out of the shell, and down in the nursery. I first found the egg pipped at daylight this morning; and before noon the chick was out in good shape. This is the way it works when the hen gives the egg its start and the incubator does the finishing up.

—say lay enough eggs to pay for the feed they require. Let me digress a little.

Some time ago I thought I had discovered a way of getting more pullets and fewer males by crossing the Leghorns and Buttercups. If the mothers were all white, the most of the chicks would take after their white mothers, because the Leghorns are a much older and better-fixed type than the new Buttercups. Well, I still think there is something in it, and now I have about 40 pullets of this cross, and these forty are just now giving me twice as many eggs as the remaining forty. Now, in this flock of forty there are almost all colors imaginable. There are at least a full dozen hens as black as any Minorca, and there are (*in looks*) blue Andalusians, Brown Leghorns, and, in fact, fair types of a dozen different breeds. It is one of these crosses that lay eggs while she is sitting; and if some of you experts would take the pains to develop this trait that you do in "breeding to a feather," for instance, you would be doing more real good for coming generations. My theory is that crossing an old and established breed in this way not only tends to throw out a multitude of sports in color, but fowls that have queer and eccentric ways and habits, as I have outlined above.

"NEW DISCOVERIES," ETC.

We are pleased to note that at least one poultry journal is taking note of our poultry department. See the following, which we clip from the (great big) *Reliable Poultry Journal* for January. It really is a beautiful large monthly, and contains a vast deal of information.

We are kept busy these days reading about the wonderful new "discoveries" in poultrydom. A writer in GLEANINGS has "discovered" that all hens lay "two eggs and skip a day, two more and skip another day, laying the eggs 30 minutes later each day." Another writer has "discovered" the best and cheapest food for laying hens. He secures from his local butcher the "lungs and lights of fat animals, which are placed in an out-building and there left undisturbed for a few days. Flies of many kinds are attracted, and deposit their eggs." When hatched the worms proceed to devour the meat, and to get fat. When thoroughly ripe I mix the mass with bran, which removes much of its offensive nature, and allows it to be handled easily." These "discoveries" are given and favorably commented upon by earnest men! And it was found in a publication which takes pride in its claim as a truthful and highly decent journal.

Our readers will notice the above are not strict quotations, neither did the editor say my "discoveries" are usually given in a vein of pleasantry; but we can forgive it, even with his implied sarcasm, for he probably felt a little sore over my criticism in regard to advertising in the reading-pages—see p. 673, Nov. 1.

In regard to the larvæ of house-flies and other insects as food for poultry, there has been some discussion. As this is the principal incentive to chickens scratching over manure-piles and around stables, I can hardly think rearing larvæ to supply the meat ration objectionable. Miner's domestic poultry-book, published 60 years ago, described and urged it very strongly. And

now I am sure I shall please the "Reliable" man still more by giving the world another "great discovery."

HOW TO MAKE INDIAN RUNNER DUCKS LAY LARGE EGGS EVERY DAY IN THE YEAR.

It is very simple and easy. Give them a big panful of corn at night, and let them help themselves to it all night long and until they have all laid an egg in the morning. Ours usually have their eggs all laid by daylight, and then they are let out into the canal, where they forage until they come home at night for their pan of corn once more. This is a remedy, too, for small and medium-sized eggs. "He that soweth sparingly shall reap sparingly" applies to getting ducks' eggs as well as to almost every thing else. If your ducks are laying small eggs a part of the time it is just because you are not giving them the needed good strong food to get up a nice "corn-fed" egg every day. The new ducks are really capable of doing wonderful work in the line of egg-laying, but to perform these great feats they must have good material in great plenty. The reason why I lay so much stress on corn is that ours seem to prefer it to any thing else. Of course, they get an abundant supply of green stuff and animal food along the canal, where they spend the greater part of the time during daylight. The following, in regard to these ducks, I clip from the *Jacksonville Times Union*:

Keep a large low dish of shell, grit, and charcoal (one of each) before them all the time. You will be surprised at the amount they will eat. Grain is not a good feed for ducks as a steady diet, but we give ours some whole corn or wheat once in a while, and they seem to enjoy it for a change. Whether it is necessary or not, we are undecided. If any thing, we would consider it unnecessary; but it makes a quick way to feed, and we generally give it to them on Sunday nights, as that is our lazy day.

There is a certain prejudice among some people against duck eggs, probably because some ducks are fed on foul food; but I can assure you that, if the ducks are fed as I advise, the eggs will be as sweet and wholesome as hen eggs. This is especially true of Indian Runner eggs. Their eggs should be perfectly white, and ducks laying green-tinted eggs should not be used as breeders. We do not have any trouble on this score now, as ours all lay white eggs. One of our local breeders finding that the grocer who was buying his eggs did not want duck eggs started selling to another grocer, and put all of his small duck eggs right in the crate with his chicken eggs, and no one was the wiser. He only took the pains not to put in any eggs that were large enough to arouse suspicion, which only proves that, if people only knew, they would demand duck eggs in preference to hen fruit. It is a perfectly harmless fraud, and one that benefits the buyer.

As the mucky season is coming on, and we all know that ducks are apt to lay their eggs around anywhere, we are trying with fair success to teach ours to lay in nests. Try it for yourself; and even if only half of them lay in the nests it makes just that many less eggs to wash.

UNEEDA BISCUIT AND THE CHICKEN BUSINESS.

Now, you need not jump to the conclusion that I am going to advise these crackers as a cheap chicken feed—nothing of the kind, although I think they might be just the thing, and perhaps just the *best* thing crumbled in milk, say, for "day-old chicks," and perhaps for the first week; but what I have

in mind is this: We have always carried our eggs to market in egg-boxes holding a dozen each, and costing about half a cent each box (in 1000 lots), and, finally, our grocer sent for a lot and furnished them free to his regular customers. Well, he got out a few days ago, and I tried for a while carrying my eggs in a basket in the good old-fashioned way; but I don't like it. I object to having my "eggs all in one basket" (may be you have heard wise advice along this line before). Well, I object to the repeated counting it necessitates, to say nothing of a possibility of broken eggs, etc. Well, just at this crisis Mrs. Root brought me a pasteboard box she had just emptied, and said, "Here! why won't this hold a dozen eggs?" It held them exactly. As they come apart pretty easily you will need to drive the smallest size of tinned tacks through the pasteboard at each end, and clinch the tack down by holding the box on the back of an ax or hatchet. By the way, I have always been pleased to see the full-page advertisement in our journal. These crackers have been a real boon to humanity—always the same thing, for sale everywhere; and any hungry mortal who can scrape up a nickel can always have a most wholesome and appetizing lunch on a minute's notice. Mrs. Root and I always prefer them to any thing else to go with the nice fresh Florida oysters that are in the market here every day in the year.

Special Notices

By A. I. ROOT

SEEDS, PLANTS, ETC., FOR FLORIDA.

Conditions, climate, etc., are so different down here from the North, that it is often advisable to submit your wants to seedsmen who live here and know what is wanted and what is best. Crenshaw Bros. Seed Co., of Tampa, Fla., issue a very neat and pretty catalog of seeds, poultry supplies, etc., gotten up specially for this region, which contains suggestions and advice to any one thinking of coming here.

THAT "ADDRESSED POSTAL CARD."

If you want a prompt answer from me, you must enclose an *addressed* postal card. One good brother sends just a plain postal, and his name at the end of his letter was such a scrawl I just had to give it up. I might paste it on the card, but I have no time for such fussing. It isn't the *one-cent card* I want—bless you, no; it is that I want you to do the work of addressing. I don't want *addressed envelopes* either. I lose them or get the wrong letter in to them, and a postal holds all I have time to say to each one of you. There is all the time before me a lot of unanswered letters, many of which, I think, I ought to answer, but I simply can not, and there is about a "wheelbarrowful" of papers, magazines, books, etc., that I am trying to get time to glance over. I appreciate your many kind words, and may God bless you all; but I really can not stand being kept indoors so much.

Your old friend,

A. I. ROOT.

THE CORNING EGG-FARM BOOK, BY CORNING HIMSELF.

The above is the title of a large beautiful book; and that is not all, for it must, in my opinion, prove a most valuable addition to the poultry literature of the world. As I have recently visited and written up briefly the Corning establishment, and frequently referred to it, it will not be necessary to go over

it again here only to say it is, perhaps, almost the first really successful attempt to keep as many as 1500 laying hens all in one building, and, we might almost say, in one room. The book contains over 200 pages of beautiful print on the very best of paper, and the engravings of every thing described are masterpieces of art. I wonder if the authors of some of the dollar poultry-books sent out with paper covers and poor print, on *poor paper*, will not feel ashamed when they come to see *this* dollar book. Every thing is pictured that they use in the way of implements and building, and there are even long folded *maps* of their colony houses, and in the back part are diagrams of all the buildings on their premises. I am glad to note that they have tested, extensively, mustard for laying hens, and it not only seems to benefit the health of the fowls, but the eggs have even better fertility where a reasonable amount of ground mustard is incorporated with their food. They use what is called mustard bran, a by-product from the mustard factories, costing only about one-fourth of the regular product. Red pepper tried side by side with the mustard gave no such result. It did not increase the laying, but seemed detrimental to the health of the fowls. Another important point made in the book is that hard-coal ashes are an excellent substitute for charcoal, lime, and grit. Where the fowls have access to the ashes they seem to care very little for their regular grit and shells. If you have a touch of the poultry fever you can not afford to be without this new and up-to-date book. If our company have not already done so, I hope they will soon make arrangements to offer it at a low figure clubbed with GLEANINGS.

After so many kind words I want to mention one or two possible objections. First, the Corning book pronounces the "baby-chick business" cruel, and advises against it. Surely they are not posted in regard to the magnitude of the business in certain parts of Ohio, and also of the number of satisfied customers who continue, year after year, to buy chicks instead of eggs. I would not mention my other criticism, were it not that I feel I must do so to be absolutely fair. It is this: The book all together is a splendid advertisement of their (comparatively recent) business of selling eggs for hatching, as well as fowls for breeding. Do you suggest to me right here that the same might be said of the A B C of Bee Culture? You are right—at least to a certain extent, and the same might be said of a great part of our most valuable rural and other books. An important item comes in here, however, and I think I can make it plain if you will listen. The Corning people first started to produce sterile eggs for food consumption only, and the first book put out by our good friends of the *Farm Journal* so stated it. So long as this was true, there could be no cause for exaggeration or for dwelling on the brightest side of the story. Well, on one page, in the middle of this beautiful book, we are told that, during the year 1910, they returned money for more than 50,000 eggs for hatching. I do not know what they get for eggs for hatching. If but little more than for those for table use, the point I am making amounts to little or nothing. If they get (like Kellerstrass), a dollar apiece (or more) for choice eggs, I feel troubled about recommending this beautiful book. Yes, I might as well own up that I feel troubled when I see some boy or girl send off for eggs that cost anywhere between a dollar a dozen or a dollar apiece. When these high-priced chickens don't lay any more eggs than those they had already, I feel *more* troubled. The poultry journals keep telling their readers to be sure to "buy the best" to start with. A woman went into a seed-store and found they had seeds of two qualities—one grade much higher in price. Looking sharply into the seedsman's eyes she said, "If I pay for the best, am I *sure* to get it?" In conclusion, I believe the Cornings will give you full value for every thing they receive, just as they have in sending out this beautiful and valuable book.

The Northern Michigan Bee-keepers' Association will hold its next annual meeting at Traverse City, March 13 and 14, 1912. Headquarters will be at the Whiting Hotel, where special rates have been secured; and in its parlor on the second floor the meetings will be held. A good program will be provided, and we hope to see many new faces as well as the old.

Editorial

Now is the time to write your senators and representative, urging their support to parcels post. Do it *now*. Parcels post will mean much to the farmer, and to all, in fact, except, perhaps, the proprietors of small stores and the big express companies.

SEND postal-card reports on how the bees are wintering. As this has a direct bearing on the price of honey, we hope our friends will respond at once. Confine your reports to two or three sentences on a postal card. Give probable winter losses, and state whether the bees are in the cellar or out. If outdoors, state whether packed or not.

WHEN TO SET BEES OUT OF THE CELLAR.

DR. E. F. PHILLIPS, of the Bureau of Entomology, offers the excellent suggestion that beekeepers consult the Weather Bureau before setting their bees out of the cellar. It is desirable to select a day in advance that will warm up along about nine or ten o'clock, so the bees can fly. It is never advisable to wait until the air is warm and balmy, and then set the bees out, because they will fly out immediately in confusion. The weaker colonies will combine with the flight of the stronger, thus weakening their own forces, and giving the stronger stock bees that they do not need.

The *best* time to set bees out is the night *before* the selected day, or in the morning of that day when the atmosphere is cool or chilly. Usually we prefer to set them out the night before, then they will quiet down before morning. As it warms up gradually they come out slowly—not in a great rush.

As a general thing it is not best to set the bees out in two lots on successive days, because the earlier lot is quite liable to rob the ones just set out.

THE OHIO AND INDIANA STATE BEEKEEPERS' CONVENTION.

THE Ohio meeting was held on the 21st, at Springfield, and Indiana on the 22d, at Indianapolis. We managed to take both in. The attendance at both meetings was somewhat small, doubtless owing to the blizzard of bad weather at the time. Dr. E. F. Phillips, of the Bureau of Entomology, gave an illustrated address on bee diseases at both conventions. He showed by colored slides the difference between the larvæ af-

fected with American foul brood and those affected with the European disease. He then illustrated the successive steps in the treatment by shaking or brushing on starters of foundation.

He made the statement that the inspection work, both in Ohio and Indiana, was accomplishing good results. Indeed, Indiana especially, he said, had reduced the amount of disease through its scheme of inspection to a third of what it had been before the law went into effect. He said that there was a similar reduction in the amount of disease in other States where systematic inspection work had been carried on. For example, in New York, when the inspection law went into effect 23 per cent of the colonies examined were affected. This percentage, when inspection was well under way, was reduced to about two or three per cent. While there has been a slight increase of late, the inspectors are holding the disease well in check. Dr. Phillips made it very clear that inspection would never totally eradicate disease, and the most we can do is to hold it under control.

State Entomologist Prof. Shaw, chief foul-brood inspector for Ohio, gave a report showing that foul brood was found in practically all the territory visited by the inspectors. While he had not been able to cover the entire State as yet, it is evident that the inspectors were improving the conditions very materially. Mr. Baldwin, State Entomologist, and chief foul-brood inspector of Indiana, showed that good progress was being made.

The general discussions at both conventions revolved around wintering, and it was natural that it should, for fears were expressed on the part of beekeepers present at each of the conventions that there would be heavy losses during the very severe winter we have just had and are still having; but from general reports that have been brought in, it is apparent that losses will be mostly along about the latitude of Springfield, Columbus, and Indianapolis. In the northern parts of both States the losses would not be as heavy, because the bees were better protected. In the southern parts the winter mortality would be less severe for an entirely different reason—because the climates are milder, and the ordinary single walls of the hives would be sufficient protection.

HOW THE BEES HAVE WINTERED.

It is a little early to get reports; but those we have received indicate that our most northern States and Canada probably will not have severe losses—particularly among those who practice cellar wintering or pack in double-walled hives outdoors; but the bee-keeper, so called, who has been in the habit of letting his bees "work for nothing and board themselves" will probably lose very heavily, even if he does not lose every bee; for the severe winter we have had has had, in the more northern localities, a disastrous effect on colonies not housed in winter repositories or properly protected in double-walled hives or winter cases. The greatest loss will occur, probably, about the dividing line between territory where it is necessary to use protection and territory where no protection is ordinarily needed. That means that losses will be most severe in latitude 40. South of that line, say Southern Kentucky and Tennessee, the mortality will be less severe because of the shorter winter season and the milder winter.

In most cases it is clearly shown that it is an advantage in the Northern States, at least, to put all colonies in good cellars or double-walled hives; yet, notwithstanding, a couple of men at the Springfield convention reported that they put their colonies in single-walled hives, and they were wintering splendidly, while one of their more careful neighbors was losing his bees in double-walled packed hives. But it is the exception that proves the rule.

SOME OBSERVATIONS ON WINTERING AT MEDINA.

On the 13th and 14th of the past month the severe weather began to moderate, and on the 15th and 16th we took a look through the bees at our several outyards and at the home yard. In the Harrington yard there was not a single colony lost, notwithstanding we had more reason to fear that yard than any of the others. The bees were nicely put up and well housed; but the individual colonies, with some few exceptions, were weak.

At the Clark yard there was a loss of only two colonies out of some eighty odd. In one case the super cover had got tipped back so that cold air blew in right over the bees, and actually chilled them to death. In the other case the cluster got into an open feeder with syrup, and half of the bees were drowned. The reduced force was not able to stand the cold.

At the home yard, which had been used for filling orders for queens and bees in the fall, we found a little different story. We first commenced on two rows at the north end of the apiary, comprising some colonies that had been made up late. Indeed, they were aggregations of little clusters from several hives that had been united. The bees, however, were well housed; but their entrances were facing north. Something like seven or eight of these colonies were dead outright, and the others were weak. Where they were dead it was noticed that snow had blown over the entrances, and that moisture

from the clusters had caused the snow to melt and freeze, thus hermetically sealing the entrances. In some other cases dead bees had clogged the entrance, their carcasses being jammed in tight so there was no chance for escape. In most cases, where the entrances were clogged or sealed tight, the bees were either dead or in bad shape. In either case it was apparent that the clusters had scattered in order to get air, had died, and dropped down on the bottom board. Late-made-up colonies do not, as a rule, winter well because they lack the stability of an old colony that has the real colony spirit.

When we went through these two rows we were somewhat alarmed; but on going through some of the other colonies, "the old stagers," that had gone through the season, and whose life had not been sapped by pound orders, we found conditions much better; but still the bees at the home yard were not in nearly as good shape as those at the two outyards already mentioned. The reason for this is, doubtless, owing to the late disturbance in filling orders and feeding and doubling up to make up. The basswood apiary was in about the same condition as the home yard, and that, too, had been used to some extent for filling orders.

The Brunswick apiary was in the worst condition of all. This yard consisted of late-made-up colonies, and all were supplied with the so-called golden Italian queens. The hives protected by winter cases were placed on a side hill facing southeast; but the location was evidently bad because of the fact that the wind blew over the hill in the rear, and then apparently meeting some counter-current was deflected into the entrances of the hives. How do we *know* this? In many of the colonies we found snow that had blown in at the entrances reaching clear up under the frames. The entrances were closed, and the mass of snow below the cluster seemed to be too much for the bees, for a third of them were actually dead, and another third will probably "throw up the sponge" within two or three weeks. The golden Italians hatched out in the fall; and as they were young bees we naturally supposed they would be able to stand more cold than the older leather-colored Italians; but as a matter of fact the exact reverse was true. Our Mr. Spafford reported that the extra yellow bees seemed to be the first to die. The leather-colored bees, though much older, were standing the cold much better. This only confirms the experience and reports of former years, that these extra goldens are not good for outdoor wintering. It is very seldom that we have been able to winter them; and why they should die before the darker Italians is not easily explained, unless it is because their hardiness has had to give place to color.

THE IMPORTANCE OF WINDBREAKS; THE RIGHT AND WRONG KIND; SOME FREAKS OF THE WIND.

The question of wind exposure to an apiary is a matter of no little importance.

Sometimes the windbreak will check the force of a winter's blast on one, two, or three rows, but deflect it on some other rows where it does a lot of damage. For example, our Harrington yard this year was moved about a thousand feet to the south and east of its previous location where the winter losses in previous years were too high. The old spot had a bad wind exposure from cleared land on all sides. This year the bees of this yard were placed in the center of an old orchard with numerous brush heaps around the outside of the apiary. They looked unsightly, but "handsome is that handsome does." We are beginning to believe that a solid windbreak, as a high board fence, is not as good as one through which the air may *sift* and *spend* its force. Notice how the railroad companies are now using open fences rather than solid ones to keep snow off their tracks. When a winter blast strikes a *solid* windbreak like a tight board fence the force is liable to *glance* and strike some other colony or colonies, doing considerable damage. At our north yard, for example, there is one row that seemed this year to suffer more than the others. This has been observed for several seasons. At our home apiary we have discovered certain locations where colonies, no matter what the strain or strength, seemed to suffer more than others. At the Brunswick yard, owing to the conflicting air currents, it was evident that the location as a whole was very bad; for how else could snow be driven into the entrances of many of the hives so that it would be two or three inches deep on the bottom of some of them? These hives had contracted entrances, $\frac{3}{8} \times 8$.

CAN CLUSTERS MOVE DURING MIDWINTER?

Another interesting thing we observed was that, even during the very severe protracted zero weather, clusters of bees would move from one part of the hive to the other. By lifting the chaff tray we could easily tell the location of a cluster by placing the hand on the super cover. In one particular case one cluster of bees during the early part of the zero spell moved from the front of the hive to the rear, then over to one corner. An examination on the 16th of February showed that these bees, after all their shifting about, were in fine shape. This would seem to indicate that the old notion, that a cluster can not move during zero weather, is a mistake. Apparently the bees have the power of increasing their temperature so that they can move to "pastures new." On the other hand, we have found clusters stone dead with all their stores eaten away from around them, yet with plenty of stores in the hive. Why these clusters did not move over to pastures new we can not say. Perhaps you may ask how we knew the clusters moved. This we determined by the changing of the temperature as indicated by the thermometer. For example, a thermometer was put in the *back end* of one of the hives while the cluster was in the extreme front. The internal temperature of this hive varied anywhere from 20 above zero to 75, while the outside temperature was down to zero

and below. When the mercury went up to 75 we thought there must be some mistake, because it was 7 below zero outside. We came back late in the afternoon, and the mercury outside had dropped down to 10 below; but the thermometer showed 75 as in the morning. We were curious to know *why* this was so, and finally lifted the cover off the super. The bulb of the thermometer had been right down in the center of the cluster. Mind you, this temperature of 75 was taken without disturbing the cluster in the least. This goes to show why that ball of bees could move from one part of the hive to the other. It had *vitality*. Now, then, the cluster that remained stationary, and starved, yet had stores within one or two inches, must have lacked vitality or something.

Some years ago Mr. G. M. Doolittle, if we are correct, reported that the internal temperature of a cluster of bees one winter was up to 98. We have never found it to be above 75. The apparent discrepancy may be explained by the fact that Mr. Doolittle's bees had probably started brood-rearing.

SIZE OF ENTRANCES.

There has been considerable discussion on this point. It is our opinion that the matter of locality and wind exposure will have to decide this very largely; but in most localities the consensus of opinion favors a contracted entrance $\frac{3}{8} \times 8$. A 1×2 inch is liable to let in field mice, and these pests play havoc with wintering colonies. In two or three cases this winter we observed that, where the entrances were wide open, $\frac{1}{2}$ by the width of the hive, the bees were much worse for the experience. We have observed the same thing year in and year out, and yet we have no quarrel with one who says he can get better results with a very large entrance. His locality probably makes this right for him.

SEALED COVERS VERSUS ABSORBENTS.

We are inclined to the opinion that a cover board of thin wood laid on the top of the brood nest, without sealing, is better than where it is sealed down tight. While this may be a concession to the upward-absorbing-packing fellows, yet we are always open to conviction, and we find that covers not sealed down allow a certain amount of moisture to escape through the cracks, and yet not enough to make the packing above wet or damp. This matter of absorbents versus sealed covers is largely one of locality. In very cold climates, if the opinion of good beekeepers is of any value, we would say, use the absorbent plan; but the packing material should be light and loose, so the moisture can escape, but not enough of it so that the heat may get away too.

ENTRANCES FACING NORTH.

We noticed in most cases where the colonies faced the north that they were not in quite as good condition as those facing east or south. A few were dead outright. While we do not think the north exposure was *entirely* responsible for this, it contributed to some extent to the result.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

B. MICKWITZ, Borga, Finland, has sent me samples of furniture nails with porcelain heads which he has used with satisfaction as spacers for brood-frames. I have also used them, and they do good work, but not so good as the heavy shingle nails.

DR. WILEY comes out on top—given a clean bill of health and a free hand. Hoop-de-dooden-doo. Good for Dr. Wiley! [Hold on a little. Dr. Wiley's enemies are more active than ever. Unless the press of the country continues to stand back of him they may get him yet.—Ed.]

CHICAGO papers report an Orpington cockerel at the poultry show, Dec. 15, valued at more than \$2000. A rooster hardly averages the value of a queen-bee. Yet some will maintain their equilibrium at mention of \$2000 for a rooster and throw a fit at mention of \$200 for a queen.

TWO MAIN divisions of Italian bees, leather-colored and five-banded, page 90. That may be all right now. Before there were any five-banded we had leather-colored and light Italians. [As we have before pointed out, the name "five banders" is a misnomer in most cases. We do not believe there are a dozen colonies showing *all* five banders in all the United States.—Ed.]

THE EDITOR of GLEANINGS gives me a lot of trouble, and now D. M. Macdonald is helping him to make life a burden for me. That Scotchman quotes me as saying "Pure Italians don't need even the paper to keep them from fighting" (when one colony is placed over another to be united), and says, *British B. J.*, 514, "Here there would be a battle royal." I don't know of my own knowledge whether Italians would fight or not; but I took your word for it, Mr. Editor, and now you fight it out with Mac and let me out. [Most Italian stock does not require any paper nor any special precaution in uniting—at least that is our experience here at Medina. But there are Italians and Italians. Some of the so-called five-banded bees, and bees from Southern Italy, are very cross. Italians from Northern Italy and Southern Switzerland are usually very gentle.—Ed.]

AN AUTOMOBILE is a thing I don't own, and have no notion of getting; yet I'm looking with eager interest for the automobile number of GLEANINGS. So long as I had an out-apiary the thought of the danger from having a horse or horses at the out-apiary or with a load of bees on the road was a constant nightmare, and I could well have paid a good price for a horseless conveyance to be rid of that nightmare. Especially do we want to know the cost for upkeep as compared with horses. By the way, I wonder how many bee-keepers pronounce "automobile" correctly. In this locality

it's generally pronounced au-to-mó-bile. The dictionary says au-to-mó-bile is the adjective and au-to-mo-bilé the noun. An au-to-mó-bile vehicle should be called an au-to-mo-bilé. Or, perhaps, better still, some shorter name. [The dictionary, so far as it relates to automobiles, is behind the times, or, rather, this is a case where an industry has made such rapid advances in nomenclature that a dictionary four or five years old is necessarily out of date. Take the word "garage." It is pronounced in a dozen different ways; but the strong tendency is to Anglicize all such French words. For instance, "automobile," the noun or the adjective, is pronounced *automob'l*, not *automobeel*. "Garage" is pronounced exactly like "carriage" except the first letter, for the simple reason that we English-speaking people could not, even if we tried, give the French pronunciation. After all, the general present-day usage should be the guide rather than a dictionary that attempts to reflect such usage.—Ed.]

MR. EDITOR, I recant, I retract, I back down, I take it all back. From your private letter I learn there is much honey put upon the market whose imperfections at top and bottom of sections are not concealed when three-inch glass is used. For such honey two-inch glass is better. (Please pass the humble-pie.) Still, you might allow me to continue three-inch glass for the sort of sections that grow "in this locality." [We see no reason why you should recant and take it all back. Personally you like the looks of your honey behind three-inch glass because it is of high enough standard so that it looks well; but a great deal of the honey thrown on the market is enough below grade so that it looks better behind a two-inch glass. Does this suggest deception? Not if we understand conditions properly. A section out of the case below No. 1 grade looks far better than the same section put behind a three-inch glass in a shipping-case with other sections of the same filling. When the below-grade section is out of the case its defects do not seem to be quite so apparent, because it is easy to see that it is all filled; but when it is put behind a three-inch glass it looks just lean enough to make it appear under weight. When placed behind a two-inch glass it looks much better—that is to say, the buyer will size it up at its real value.]

But your honey is above No. 1 grade and better—at least what we saw in the New York market was some of the prettiest comb honey we had ever seen. It would look well, even behind four-inch glass. So we see no reason why you should recant unless your original statement applied to all honey put up indiscriminately by producers generally.—Ed.]

NOTES FROM CANADA

J. L. BYER, Mt. Joy, Ont.

The old question as to whether we should shovel snow away from the entrances of hives or not will be puzzling many at present. We cleared snow from in front of some of the hives, and since this terrific cold spell has come we have been wishing we had not done so. A few days ago I went to the Cashel yard intending to clear the entrances; but on lifting up the packing from a number of colonies, and seeing them so quiet, I decided to leave them alone. Needless to say, the decision has not been regretted. As long as the entrances are clear of ice, I believe that good rather than harm will result by leaving the snow around the hives during extremely cold weather.

Mr. Davison, of Unionville, a very successful beekeeper in this locality, has a contrivance that fits over the entrance something like a vestibule, which prevents clogging of the entrance, and at the same time insures an air space around the hive, and will allow the bees to carry out their dead if they wish. Then if the snow does not *drift* over the fronts he *piles* it there doing cold weather. Last week I visited the yard, and the hives look like snow mounds more than any thing else. He is one of our best winterers, and for a year like this the plan is all right. Even without the snow, the contrivance is an excellent feature in that it prevents the wind going directly into the hive, and also keeps the sun from enticing out the bees during cold spring days when they are better inside.

On page 90, Feb. 1, I notice that the Board of Supervisors of Imperial Co., Cal., has passed an ordinance forbidding bringing any bees into the county. This is certainly drastic enough. I wonder whether the law would stand the test of a higher court. If a law of that kind were passed for the purpose of keeping out *diseased* bees, well and good; but from this distance, as the law is worded in GLEANINGS, it looks like a very arbitrary measure. Suppose a man were moving into the county for good reasons, and with no intentions of going into beekeeping on a large scale. He has a few colonies of bees in good healthy condition; but because of the law supposed to be in force he is forbidden to bring them in, even if they are just over the "townline" of the said county. It would be human nature to try to test the validity of such a law, and I really should like to see some with enough ginger in them to see what would happen if they dared to take in a few perfectly healthy colonies.

Regarding that article of mine on finding queens, p. 619, Oct. 15, some have wondered why I did not use a taller tent, so that I could have stood erect while at work instead of being forced to be on my knees all of the

time. In explanation I will say that the apiary is in a yard that is full of cherry and other low trees, and it was very difficult to use the tent I had in some cases, to say nothing of one much taller. Some other friends have suggested the idea of getting rid of the field bees before starting to hunt for the queens; and while I had thought of this before starting the work, the robbing tendency of the bees at the time I was there made me fear to demoralize unduly the colonies for fear there would be trouble after the work was done. As intimated in the article referred to, many plans that will work when no robbing is to be feared, are not practicable at a time when no nectar is coming in, and the bees will go wild if hives are opened when not under cover.

When sending in notes for Feb. 1st GLEANINGS I stated that the weather up to time of writing (Jan. 5th) had been very moderate. Since then we have had the most severe winter on record, and the official figures from the Toronto observatory state that January of 1912 had the lowest average temperature they have recorded. Since Jan. 5 we have had nothing like a thaw; and this morning, Feb. 10, the thermometer is 25 below zero—the lowest I have on record for our locality. With six weeks of steady cold weather, certainly things are not looking any too well for bees which have been wintered out of doors; but an examination shows that the bees in packed hives are wintering well so far as external conditions indicate. By the way, I have 20 colonies wintering outside in hives made of double boards with cardboard between—no packing on sides or ends of hives, but an abundance over the frames. There will be a different story to tell about them; and for the present, suffice it to say that they are veritable ice-boxes, and I am having a big time to keep the entrances free from ice. At a later date I hope to say more about these, for just at present I would have to do too much guessing to give any thing like a reliable report. Yesterday the thermometer stood at 14 below, and, as already stated, this morning it is 25 below. As I had not looked at the thermometer inside the hive for over a week I thought it would be well to see how things were going after two days of such very cold weather. The reading was 31 above, which makes a difference of 56 degrees between the outside and the inside of the hive. The thermometer was at the outside of the hive about 3 inches from the side of the cluster, and was suspended in the hive with the top slightly below the tops of the frames. Possibly the difference between Medina readings and mine may be accounted for by the depth the thermometers hang in the hive; for, the lower they hang, the colder they will register.

Bee-keeping Among the Rockies

WESLEY FOSTER, Boulder, Colo.

Twenty-five days' work for each one hundred colonies should be all that is required during the year. A careful system is necessary to accomplish this, but there are men who are doing it. With the aid of autos the number of working days may be reduced, no doubt. One of the chief causes of lost time is unfavorable weather just when out-apiary work is to be done; for if a rain starts in while at the outyard all one can do is to rest and wait, or go home, unless there is a shop where beework can be done.

CLIPPING QUEENS—DOES IT PAY?

Here is a point worthy of thought: The largest and most successful honey-producers do not clip their queens. These are the men who sell from one to two carloads of honey a year, and have the largest bank accounts. You will notice that I have said *producers*. The men would probably not claim to be the best beekeepers, but they carry on their operations on such a large scale that they do not have time to hunt up queens and clip them. They claim that it does not pay them with conditions as they are in Colorado.

BEEKEEPING IN COLLEGE COURSES.

Agriculture is fast being introduced into our schools, and nearly every high school now has domestic-science and manual-training courses with a fine equipment. There is a dearth of scientific beekeepers; and if we could get courses introduced into our schools of agriculture it would advance the industry very much. What would it be worth to the State if in every agricultural short course the principles of beekeeping could be taught? It would raise the status of the average beekeeper very much.

It is simply up to the beekeepers in every State to take up this matter. We are going to have something very soon now in Colorado, and we shall be able to train our young people—some of them at least—to keep bees right. Colorado is a ripe field for better beemen, and we must have them to do our industry justice.

THE CENSUS AND COLORADO BEEKEEPING.

Colorado lost 20 per cent of her beekeepers (about a thousand) in the ten years from 1900 to 1910. During that time, however, she gained 20 per cent in bees, or about 11,000 colonies. The value of bees increased from \$195,000 to over \$300,000. Foul brood has to take most of the blame for the loss of beekeepers, although the specialists have been buying the small beekeeper out in many instances. I doubt very much whether the figures given are very accurate, as

there are many bees kept in towns, and then some beemen would be slow about giving in the full number of their colonies for fear the assessor would get hold of the list; for many a farmer would be suspicious as to whether it was merely for the federal census or not. The census, nevertheless, has given the general trend of Colorado beekeeping in a satisfactory way.

"THE CHANGING ORDER."

The expensive methods of distribution are not going to last much longer. There is a determination on the part of the consumers to deal as directly as possible with the producers. Witness the work of Mayor Shank, of Indianapolis, and hundreds of others scattered over the country. Many cities are establishing or have established municipal markets where the producers can take their produce and sell directly to the people. Whatever plans the National Association undertakes, it will be well to adapt the procedure to the marketing movements of the times. An economical method must be devised to supply each market with the honey it demands, and to keep all supplied and none overstocked. The method of consumers in going to the markets with their baskets is too wasteful of effort. Buying clubs or associations will work better. There are buying associations already in operation, and it would pay some of the beekeepers to get in touch with them to reach these consumers.

GARDEN, ORCHARD, POULTRY, AND BEES.

When is a beekeeper not a beekeeper? When he allows the bees to work for nothing and board themselves, while he farms, gardens, and raises stock. This need not be, for some of our very best beekeepers raise poultry and have a profitable garden, and some of the largest producers of honey raise, in addition, apples, potatoes, or onions by the carload. Colorado has lumbermen, stockmen, farmers, fruit men, and business men all successfully interested in bees. Several bank presidents got their start with bees, and there are several bank directors who are keeping bees for the money there is in them. I like to see a man, though a beekeeper, who is alive to the possibilities about him. I would just as soon work in my acre orchard as with the bees, and sometimes I like it a little better. The principal part of one's living will come from the garden vegetables, apples, plums, and strawberries. The cow and chickens help out, so that, with the cull honey that is not fit to ship, we find that the grocery bill is easily cared for. The main honey crop and the shipments of apples will be used to build the new house or to extend the business.

BEEKEEPING IN CALIFORNIA

P. C. CHADWICK, Redlands, Cal.

CALIFORNIA STATE BEEKEEPERS' ASSOCIATION REPORT.

On February 8 the 22d annual convention of the California State Beekeepers' Association ended its three-day session. Every thing considered, this was the most business-like and harmonious session of its history.

The way for many needed reforms was blazed, and plans which were made were left in the hands of competent committees for further advancement. Needed laws were drafted, helpful resolutions were passed, and, best of all, between the North and the South the hatchet is said to have been buried.

To enter into the details of proceedings would be a great task, and much of it dry reading, so I will merely state briefly some of the work done.

Every one who was on the program, and could be present, did his part well; but some special recognition is due to certain members whom I shall name. I wish to mention one man especially, who, though not alone in the work, certainly had most of the burden upon his shoulders—Mr. A. B. Shaffner.

The treasurer's report showed a neat balance, which in itself indicates the prosperity of the association.

Mr. G. L. Emerson's paper, "One Thousand Members in 1912," was one that commended itself to every member present. His ideas of individual work for the increase of membership, crop-report recommendation, and a perfect organization collectively were timely, and to this end a subscription was started to raise funds that we may be able to coöperate with other organizations of the State. Mr. Emerson explained that there is no feeling against the northern association.

Here I might add that, as every member can vote by proxy, it seems that there should be no longer any trouble about representation; for one man from the north can take every member's proxy he may secure, and vote it as he sees fit.

At the evening session on the 6th the lecture, "Some Wonders of Our Little Co-workers," by Prof. Ralph Benton, was the best of its kind I have ever heard. He described and illustrated the anatomy of the bee. Mr. Benton is, without doubt, the scientific man of our association. His lecture was not as fully appreciated, however, as it should have been, for some take but little interest in the scientific part of the industry. On the other hand, those who were interested were intensely occupied in thought during the lecture, and had only praise for Mr. Benton.

Perhaps the special feature of the morning session on Feb. 7 was "Queen Rearing," by Henry Perkins. This subject seemed to

appeal to the members at this time especially from the fact that European foul brood is spreading in our Southland and queen rearing and introduction have a special part in the eradication of this disease.

One topic of the afternoon session was "The Black-brood Epidemic," by J. D. Buxby, who is now a recognized authority on this disease. His remarks were eagerly listened to; and in closing, when he exhibited two frames of diseased brood nearly the entire assembly made a rush to examine them, indicating to what extent beekeepers are exercised over black brood or European foul brood.

The report of the county inspectors was made at this session. The remarks of Wm. H. Allen, of Ventura Co., and J. E. Pleasants, of Orange Co., were exceptionally valuable, as they dealt primarily with facts regarding the number of colonies inspected, and the diseased colonies found in this and previous years, showing the progress of the inspectors in their work.

The election of officers resulted in the choice of Mr. J. W. Farree as president, and the unanimous re-election of the secretary-treasurer. Of our president I can no better express my thought than to say he is a live wire—efficient, energetic, and enthusiastic—meeting work half way.

The session closed with reports of various committees and delegates. Many topics of interest, on which I have no notes, may appear later in this department.

The practice of California honey dealers in quoting honey at ruinously low prices, simply to lower a local market for their benefit, was unanimously condemned. In the future, beekeepers will be on the lookout for such dealers.

The committee on forest reserves made a recommendation that, if secured, will put beekeeping on a par with some other industries on forest reserves.

The loss by death of so many prominent beemen of State and nation was noted in suitable resolutions. Some changes in the constitution were recommended and adopted.

A resolution introduced by G. L. Emerson, asking the county board of San Bernardino County to remove the bee inspector of that county for sufficient cause, was adopted.

Mr. Delos Wood was voted life membership in the association. This veteran of the rebellion and of the bee business, now in his seventies, has suffered the loss of practically all of this world's goods by fire, including apiaries whose value reached the thousands.

[It has been stated that there are 50,000 colonies in Los Angeles Co. alone. This gives an idea of the extent of the industry in California.—ED.]

Conversations with Doolittle

At Borodino, New York

SUCCESSFUL BEEKEEPING

"I am a man with limited means, and must do something to make a living for myself and family. I have fallen violently in love with bees, and have ten colonies. I have been wondering whether I could not build up in the bee business till I could make enough of a success of it so that I could spend my whole time caring for the bees, and thus be doing something that I like. Therefore I take the liberty of asking you to say something along this line in GLEANINGS."

"The one thing in your favor is your love for the bees. Occasionally one may be successful when going into a business which he is not in love with, simply because he enters into it for the money he hopes to make out of it; but this is the exception rather than the rule. Except to the man who has missed his calling, there is real fun and play in all of the energy put into that pursuit which one has chosen. I have known people to be so engaged in their pursuit, and to love it so well, that the most exciting ball game was more tame to them than the same time spent wielding the hoe in some favorite field of potatoes. Scores of others exert themselves in playing ball throughout some sultry afternoon, calling it the height of fun, thereby wholly unfitting themselves for the next day's work in the field, doing scarcely half of an average day's work, and considering what they did do as only drudgery. It would be easy to prophesy that "successful potato culture" will not be written opposite the name on the score of such at the end of life's journey. Therefore, this axiom can be laid down: 'To be successful in any calling in life, the one entering it must have a love for that calling.'

"Notwithstanding this axiom, it must be further said that, from the calling chosen, at least enough must be derived to support the one working at it and his family. Otherwise, there must sooner or later come a turning from that calling unless financial aid comes from some other source. I remember a well-to-do man who went into beekeeping for the love or pleasure there was in it, using this same beekeeping as a side issue as he called it. A year or two later he was telling of the added profit that came to him from the bees. I remarked that I understood he was in the business for the pleasure there was in it. 'Right you are,' he said; 'but the greater the profit, the greater the pleasure.'

"I must confess, as I look over my forty-two years of life as a beekeeper, that, while there has been a rare pleasure in the work (Mrs. Doolittle has often said, after calling me again and again, that I think more of the bees than I do of my dinner), that my main object has been to gain a livelihood and to secure money for the comforts and

pleasures of life. And while I have taken great pleasure in my bees *all* of these years, and from this life in the open has resulted the robust health that can not be gotten in any business requiring indoor employment, yet neither pleasure nor good health would have kept me faithful to beekeeping had there not come from it a good living, and something besides for 'a rainy day.' And I am as free to say that I consider it doubtful whether any beekeeper will ever reach the financial stature of a Morgan, Vanderbilt, or Gould; yet if rightly followed, and with a love that will keep one at it through seasons of failure in nectar secretion as well as in prosperous seasons, apiculture will prove as remunerative as almost any other branch of agriculture. But without the necessary *love* for the bees the poor seasons, as we call them, when the 'heavens seem as brass' throughout the time of all nectar-yielding flora, discouragement is sure to come, the business to be neglected, and blasted hopes and failure are the outcome. Thus it is that this *love* part in any business is the anchor which holds through storms, and makes success certain when the 'clouds roll away.'

"And the chances of success *every* year are much better in these days of comparative swarm control, trolley lines, and automobiles, than when we older ones started. It is a rare thing that an entire failure of nectar happens over a large area of country; and very many times when there has been a partial or nearly entire failure in the secretion of nectar at the home apiary, I have secured at least a fair yield from the out-apiary five miles away, or *vice versa*.

"Now, if it happens that your environment keeps you in a location not blessed with the desired nectar-producing flora, if you are near a trolley line you can locate out-apiaries along this line as fast as your bees increase sufficiently to warrant it. Or if you can afford an automobile, these out-apiaries may be located in any place of abundant nectar-secreting flora, and thus the chances of success be far better than in the slow days of forty or fifty years ago. I can hardly realize the possibilities that are before the young, energetic man of today, who, with a love for the pursuit, goes into beekeeping."

The Double-walled Hive Better Even for the South

I have kept bees in three of the Northern States, namely, Wisconsin, Michigan, and Indiana, and have found the double-walled hive the best for cold weather. I have proved it to my own satisfaction again and again. I am now in Southern Alabama, and I find again that the double-walled hive, when well ventilated, is also the best for hot weather. The air-space gives an even temperature so that no combs are lost by the heat, and the bees do not remain on the outside of the hive on hot days.

Magnolia Springs, Ala.

E. DEUSENBERRY.

General Correspondence

IN WHOSE LOCALITY?

Paper-covered Hives with Large Entrances versus Double-walled Packed Hives with Moderate Entrances; do Bees Prosper in a Zero Temperature?

BY ARTHUR C. MILLER.

So the time has come when one must head every article "In this locality." Forsooth, I thought the veterans at least could remember that, but it seems not. Hold! Ah, ha! Ernest is to blame. It seems that he picked out the boys to make the reply. I wonder why he did not pick some one in Texas.

Little did I think that I was going to step on the pet corns of those Canuckers when I wrote that article; and, in fact, I was no more thinking of them than I was of the boys in the tropics. Well, boys, see here. You needn't give up your chaff hives. I'll let you use them as long as you wish. You don't intend to give them up? Well, then, what in thunder are you making all this pother about? You fellows have forgotten—well, never mind what. I'll just ask the other boys to turn to Holtermann's eulogies of cellar wintering scattered through the bee papers. No, Holtermann, I'll not shut up. If cellar wintering is as fine as you so long and so forcefully maintained, why are you now using the formerly contemned chaff hive? I like to hear a man try to explain away facts—if he doesn't stutter.

And there is Byer. Hm! Say! just because you got the better of me once, don't let it make you over-confident. Let me see; you once tried my black-paper plan of wintering and fell down on it. And if memory serves me rightly you modified my instructions *just a little* because you thought I had erred in some points. And now you want to put the blame on me. If I am going to try a man's plan I'll try it just as he gives it; and then if it does not work with me I'll try it with my notions tacked on.

Now, you two boys hug yourselves—and each other if necessary to give vent to your ecstasy—and get all the fun you can. The editor has up his sleeve something else along the line of "cold storage" of bees which, mayhap, will cause you to let up on poor Miller and take serious thought unto yourselves.

After the foregoing was written, GLEANINGS for Feb. 1 arrived, and I have carefully read what is written there. One important point stands out strongly; that is, that a temperature of freezing within the hive when it is zero outside is considered "keeping the bees warm." In my own experience, bees stand and prosper in a zero temperature as well as in one thirty degrees higher.

It is exceedingly hard not to restrict the entrances in the spring, so strong is old belief; and restricted entrance with black pa-

per, when it is unsafe for bees to fly, is sure to bring disaster.

A careful comparison of two apiaries, one of which had the entrances reduced as soon as it was safe to do so, and the other out of convenient reach at that time, and hence left with the full entrance, showed no appreciable difference in results; and as labor which is not profitable is eliminated I now let the entrances alone.

As to the application of black paper: As usually put on, it only partly fulfills its intended purpose. Tied down with string, or secured with a few short pieces of lath, it is of little help. It should be put on so no air can pass under it—that is vital. One can not blow far into a bottle; and if the neck is crooked and the inside filled with obstructions, no draft will reach the bottom; and on such order is the interior of a properly papered hive.

Again, the editor makes a most grievous mistake in likening a cluster of bees in winter to a radiator. They are the reverse of that, and every effort of their life and behavior is to minimize radiation. Study such a cluster, and analyze it and see. Also wax is a very poor conductor of heat, and the combs help materially in maintaining steadiness of cluster temperature.

I note one factor as I see it, or I may be mistaken. It is difficult to be sure from mere description; and that is, that colonies in the regions of prolonged cold seem to go into winter quarters with more bees than they do here. If this is so, it will explain some of the differences between Mr. Holtermann's observations and mine. Also these big (normally there) colonies may tend (have?) to breed earlier than they do here; and that, if so, will explain higher internal temperature.

Another factor is to be noted. The sun is higher at parallel 41–42 than it is at 44–45, and this may be of considerable importance.

Now you boys just stick to every old plan you want to, and jump on any new thing you please, whether it is in "your locality" or not; and the more unnecessary paraphernalia you cling to, and the more needless operations you go through, the easier it will be for me to compete with you.

But you may even yet be right for this locality. We are having the hardest winter for bees in thirty-two years; and if the bees come through it safely under my system, it will be fully vindicated.

Providence, R. I.

[Bees can stand a great deal more cold than we think. There are some conditions under which they may freeze stiff, and yet not be much the worse for the experience. The same is true of fish. Admitting all this to be true, we believe that the bee is essentially an animal that thrives best in a moderate temperature. The inside temperature of our double-walled packed hives,

away from the cluster, varies from 20 above to 75 during winter. Yesterday, with a temperature outside of 2 above zero, we took the reading from a thermometer shoved through the packing into the cluster of bees in one of our double-walled packed hives. The cluster was not disturbed, nor was the hive opened up when the reading was taken. The inside of the cluster was 75. Later in the day we took another reading. The cluster temperature was the same.

While bees under some conditions can stand severe freezes for a short time, our experience at Medina indicates that it is hard on them. If plenty of packing and a double-walled packed hive will make the air surrounding a cluster of bees from 20 to 40 degrees *higher* than the outside temperature, it imposes a much less strain on the vitality of the bees. We therefore believe that *any* system of protection that provides a difference of only two or three degrees between the outside and inside of the hive would not work in this locality nor any locality in the vicinity of the Great Lakes. Here we are liable to have long continuous cold—not short zero snaps of a day or two.

It is the *long-continued low temperatures*, often accompanied with high winds, that make packing, and lots of it, essential for outdoor wintering. Our correspondent has a different set of conditions, and we do not say that his scheme of winter protection is not the thing for his locality.—ED.]

WHAT THE NATIONAL BEEKEEPERS' ASSOCIATION WILL DO THIS YEAR

BY E. B. TYRRELL

As every beekeeper knows, the meeting of the Board of Directors held in Detroit, January 23, was probably the most important of any board meeting held in the history of the Association. Plans of reorganization had to be considered as well as just what the Association would and should do for its members.

One of the most important needs of the beekeepers, as it appeared to the directors, was an accurate knowledge of crop conditions. To get this, it was decided to send out crop reports early in the season to every member, and, from the information so obtained, advise the members, either directly or through the bee journals, as to conditions.

The Board also found that the question of honey packages was an important one. At the present time there is not nearly the uniformity there should be. No special weight of tin or size of can has been adopted in the past, and many shippers were using a tin entirely too light. Samples of honey-cans were inspected by the Board, with the decision that the Secretary be instructed to make the best possible arrangements for furnishing the members with the tin honey packages the coming season. The orders will be handled directly through the Association office, and will not be sent by the member to the can manufacturers as in the past.

In discussing the question of packages for comb honey, and realizing that there are a number of different kinds and shapes in the market, it was thought best that, in order to promote uniformity of a comb-honey package, the Association should take steps to secure for its members, at the lowest possible prices, the double-tier 24-lb. shipping-case which was adopted by the Association at its last convention.

These cases could be furnished according to specifications, so that every member buying through the National would be using exactly the same case as every other member. In order to induce a more general adoption, it was thought advisable to furnish them at a low price. The secretary was also instructed to investigate paper shipping-cases, as well as glass packages. This action was not taken with an idea of getting into the supply business, but to promote the using of uniform packages by the members, which then will simplify the question of marketing, and eventually raise the price the beekeepers can obtain.

The question of marketing honey was thoroughly considered, and many plans were presented. The one finally decided upon was that, for the coming season, the National Association should act in the capacity of broker for its members where desired. It is not expected nor desired that all members ship their honey through the Association; but realizing that many are not in touch with the best markets, it was thought that no better move could be made than to assist these members in obtaining the proper return for their honey crop. To do this, selling agencies will be established in several of the larger cities, and the sales will be directed through the Association. A member having honey to sell could first get instructions from the secretary, who is expected to keep in close touch with market conditions, take into consideration the freight rates, and then give the member full instructions as to shipment. The association does not intend to buy and sell honey, but simply to assist the producers in finding the best possible market.

The promotion of local branches will be encouraged; and wherever a local branch desires to get out a booklet, such as has been used by the Michigan Association, assistance will be given by the National Association. This feature will be encouraged. The advertising of this booklet will be cared for by the National, but will probably be confined on the start to the four bee journals.

Detroit, Mich.

Failure in Cuba Honey Crop

Both the summer and winter crop of honey have been almost a complete failure here. From 1500 colonies I got only 110 barrels of 50 gallons each. No rain until May was the cause of the failure of the summer crop, and no rain all summer; then three weeks of it in the heart of the honey season—the cause of the failure of the winter crop. A crop, according to former years, would have been 300 barrels. Moreover, the price was good—from 40 to 46 cts. a gallon in Manzanillo.

FRANK REIMAN.

A summer view of one of Allen Latham's apiaries.

A CONTRARY BEEKEEPER

A Nutmeg Stater who Defies All the Rules of
Bee Culture, and Wins

BY ARTHUR C. MILLER

Bee culture is a tradition-fettered industry. As Methuselah said, so must it be; and he who dares preach contrary to the teachings of the fathers is *per se* a heretic, an outcast. Lift your voice in questioning of the established order, and at once you are considered an iconoclast. Blessed be all such, for they are the hope of generations of

beekeepers yet to come. Askers of awkward questions, up-setters of pet theories, disturbers of the peace, shatterers of reputations! May their shadows never grow less.

An adopted son of the community famed for its wooden nutmegs stands preëminent as an iconoclast in apicultural matters, and they call his name Latham. Solid of build, sandy of complexion, he looks out of a pair of twinkling eyes in a manner both cordial and disconcerting. Is it to laugh at you or with you, you know not. State your case most cautiously, lay down the law point by point, establish your position beyond seem-

A part of the same apiary in winter.

Some store combs from Latham's "Let Alone" hive. The four show how the bees "work back," the full combs being next to the brood chamber.

ingly possible dispute, and with one word or one careless question he will turn your carefully builded structure into a tumbling house of cards. Oh! a canny boy is Allen.

As an observer of bees and their work, he stands second to no one. As a beekeeper he is never content with what he has done, but must do better. And to him, "better" means not only more product and higher quality, but lesser cost, a matter in honey production so rarely spoken of that one may well doubt if it is often thought of. But it is the "motif" in Latham's symphony, and the marvels it has led him to do would fill a book. Tell him that a saving plan which he would adopt is not feasible, and you wave a red rag at a bull. He will do it, even if it is impossible. Keep away from Allen Latham if you want to plod along in the tortuous and shady path of your granddaddy; for if you once get under the magic power of his methods, your days of self-complacency are numbered.

Just think of a man examining his colonies and gathering his crops—bumper ones too—at Christmas time, in bleak old New England. For instance, he this year took the crop from the hives of one apiary on

the 6th day of January, with the temperature at ten degrees Fahrenheit, and the wind at fifty miles an hour. No, nothing crazy or suicidal about it. He has done it for years and is steadily increasing his bees and his crops.

The hive and the system with which he accomplishes this and other seemingly impossible things are well worth a description, and the principles involved are worthy the study of every serious beekeeper. The "Let Alone" hive and system is the title he has applied, and most fittingly too; for some of his colonies he sees but

once in a twelve month, and then in mid-winter. A big black box three feet long, a foot and a half wide and high, is this hive. At first glance it looks much like the old "Long Idea" hive of General D. L. Adair, and it is and it isn't. The Adair had the entrance in the middle of one side; the "Let Alone" has it at one end. The cover telescopes about three inches down on the body, and the whole is covered with a good grade of one of the asphalt roofing-papers black in color. Nice and cool in a blistering August day, eh? Don't you worry. It

Latham's nucleus-wintering and honey-handling house. The nuclei are shown on shelves between the studding where they are convenient to handle in the summer, away from weeds, and out of the reach of toads and other vermin.

This photograph shows a part of my apiary of 40 colonies under a good shed 75 feet long. I have very little time to work with my bees, but I improve every spare moment I have. This spring I am going to give each colony two supers of sections, and if it is a good honey year I will have plenty.

T. C. HAMBLBY, Santa Clara, Cal.

works. Most of the lumber used is half-inch box stock. The floor is nailed on, and has three rugged cleats across the under surface.

In the Adair hive the queen had the run of all the combs; in the "Let Alone" she is restricted to the seven next to the entrance. And the frames outclass the Jumbo, being $17\frac{1}{2}$ inches long and 15 inches deep, with ends and tops "closed." Along the upper part of the hive sides are nailed strips on which the frames hang, and in the lower corners are beveled strips against which the bottom corners of the frames touch, so that, when the frames are in place, the hive is virtually double-walled and air-spaced.

The first seven frames are wired, and fitted with full sheets of foundation; the other fourteen have a vertical bar in the center, are without wires, and are fitted only with starters. Back of the seven wired frames is hung a sheet of excluder zinc, and this serves to separate the brood from the surplus compartment. The entrance extends away across the front of the hive, eighteen inches, and is one inch high. It is permanently guarded against the ingress of mice by a row of wire nails. And it is left wide open for three hundred and sixty-five and one quarter days in the year. Mark that, you skeptics.

The surplus chamber is approximately $17 \times 14 \times 22$ inches, and will hold about 150 pounds. If it so happens that the crop is removed in the fall, then it remains empty all winter. A most beautiful way to kill the bees, isn't it? Just think of a colony of bees in the front part of such a box with that great empty chamber behind it, and

eighteen square inches of open doorway! A man who would seriously consider keeping bees in any such fool way as that must surely have something the matter with his brain. Well, he has, but not on the line of foolishness—oh, no! only of progressive thinking and of daring.

It is not enough that he should make bee-keeping in such hives a success in sheltered spots; but he must needs attempt the impossible, so he planted colonies here and there on the upper end of Cape Cod, about the last place on earth to expect success in honey production. And there again he fools you. His reputation for veracity is good; but when he talked of an average of 150 pounds to the colony down on that bleak sand spit, one man at least had to go and see how bees extracted nectar from sea-water. And the honey was there—great sheets of pearly combs full of their golden store, and the bees tumbling in with more.

The gales from the wide Atlantic appear to be impotent against the bees' work in summer or their comfort in winter, for there those wide-entranced hives stand all through the storms and gales, heat and cold. For most of us the bees would promptly become quite dead; but not for Latham. They dare not. That wizard has filled them with such a sense of fear or something, that, whatever he says, they do. He has even persuaded them to abandon the classic "bee-line," and one finds his bees ducking and dodging around the sand dunes and following along the railroad cuts, zigzagging here and there and anywhere out of the wind till they are close to home, when with a dash they plunge over the bank and down into their hives.

The hives are usually stocked by running a natural or artificial swarm into them. The bees are then instructed to set up house-keeping, provide themselves with a proper amount of supplies, and put aside a suitable surplus in return for the care (?) and oversight he has given them. Talk about the high cost of living, and then think of taxing those poor little bees one hundred pounds of honey for the rent of an old barn of a box without any stormdoor on it!

But the insatiate man is not content with that, but, forsooth, insists upon the bees sorting out the various kinds of honey for him, each kind in a comb or combs by itself, and the meek little creatures do so, as far as the flows permit. It happens in this wise: The bees fill the brood-chamber and then crowd through the zinc, build comb in half of a frame and fill it, then in the other half, then into the next frame, and so on. He has merely applied his hive and frame arrangement to fit the habit of the insects.

Yes, they swarm sometimes, but not very often; and as most of the queens are clipped they seldom depart, but return and settle down with the young queen, which, of course, is against the rules of the game, but those don't count with Latham.

He keeps bees in the conventional hives, too; has some eighty odd colonies thus; and that he does it well, witness the summer and winter views of one of his yards. His home yard is an interesting place to visit, and there will be found all manner of hives, appliances, and experiments. One of the striking features is a honey-house built "inside out"—that is to say, the studding is on the outside; on the inner face of that, heavy water-proof paper; and within that, matched sheathing. It is placed on a foundation of stone laid dry, and the shallow cellar is open on one side, so that literally the house is hung in the air. GLEANINGS for Jan. 1, page 3, says, "Do not winter in a closed room above ground." But Latham winters thirty or forty baby nuclei in this closed room above ground, and has done it ever since 'twas built, three or four years ago. So exceedingly careless of him to do such a thing without consulting anybody!

And those baby nuclei! utterly different from any used by other folks. One nice little entrance-hole, easily defended against robbers, isn't at all to his liking, so he has two such holes—perhaps reasoning that, if

Laughlin Falconer, 94 years old, a pioneer Chicago beekeeper; his son, and one of his assistants.

one is easy to defend, two will be twice as easy. The blooming combination works just because it shouldn't.

To feed them he floods the lower part of the little box (previously water-proofed) with syrup—a jolly nice way to start a robbing scrape, but it doesn't. His nucleus construction and operation is a fine story in itself, and perhaps the editor can persuade him to tell; and if so, let the reader be warned that, no matter how improbable things may seem, or how weird his tale, it is so if he says it, even though every other beekeeper has tried it and failed.

'Tis jolly lucky for Allen Latham that he lives in the twentieth century rather than in the days when belief in witchcraft ran riot.

Providence, R. I.

BEEKEEPING IN A CITY

A Great Record by a Man who is Now Almost a Centenarian

BY J. L. GRAFF

The accompanying picture show a part of an apiary that has helped to furnish a city now numbering twenty-two hundred thousand people with honey for sixty-seven years, and is still producing 9000 lbs. a year. It not only in a large measure has furnished a living for its owner, but has supported a whole family.

In the last thirty years it has produced 135 tons, and the output for the previous thirty-seven years would run the total production to considerably over 175 tons.

This apiary was started on the banks of the Des Plaines River, Illinois, in 1844. It was started from the capture of a single colony from a bee-tree, and hived in a barrel.

Four years later, all the accumulation of bees and honey was moved to a farm of 160 acres which is now located inside the city limits of Chicago. The man who started this apiary is still operating it at the age of ninety-five years. His name is Laughlin Falconer, and he is assisted by his son, William W. Falconer, who says that there has never been a failure in more than three-score years. There were years in which the production of honey was less than in others, but there has always been a paying quantity after allowing sufficient to winter the bees.

The little workers, during most of the time, have foraged on sweet and alsike clover, and much on a prairie bloom that closely resembles a sunflower.

The bees have always been sheltered in winter in the crude manner shown in the photograph. They are now confined in modern hives, each of which in the cold months is first wrapped in burlap, then in old newspapers, and then a whole bench is buried in leaves, and the leaves confined by weather-boarding—tops, sides, and ends. In late years the whole of the product to be sold has been extracted and disposed of in gallon cans.

This near-centenarian apiarist, however, is but one of a number of city beekeepers in Chicago. Not long ago, at a meeting of an association in Chicago, representing several States, fully 25 out of 150 beekeepers were Chicago apiarists. When the big

drainage channel was built, and huge banks of clay and other material were piled up along the canal, this deposit in a short time was covered with a rank growth of sweet clover; and on this, bees from a wide area of country worked with great results.

One of the mail-carriers of the Chicago postoffice is one of the most successful beekeepers in the Middle West, operating his bees in an expansive backyard. This man gave considerable attention to the breeding of bees of mild disposition, and he claims to have had noticeable success so that his family are able to use the yard; and pedestrians can pass the place without being attacked by the bees. This apiarist sets up the claim that a good disposition may be bred in bees, just as other breeders secure this trait in live stock.

Chicago, Ill.

PREVENTING BEES FROM GETTING THE SWARMING IMPULSE

A Vestibule Attachment Communicating with an "Annex" Providing Extra Room

BY DR. L. A. SIMMON

In presenting this device to the bee-keeping public I am conscious that there is a good deal of skepticism in reference to mechanical devices that purport to facilitate the control of bees. But I am also confident that the invention will produce the same

An apiary in Chicago that has produced, during the last 97 years, over 175 tons of honey.

results for others that it has for me, and therefore meet with general favor. The details of its construction are based on a thorough working knowledge of the instincts and natural activities of the bees, and every step in the system to be described in the application of the swarm-controller in its various uses and functions is made to conform to these natural laws. There is, therefore, no possibility of failure or disappointment except through gross carelessness or neglect of duty on the part of the operator. I have tested it for a number of years, and what I shall say is the result of experience and not theory. It very greatly reduces the labor, and simplifies the processes of bee-keeping.

The control of the swarming impulse during the honey harvest is one of the most important subjects to the beekeeper. In my hands the device has been uniformly successful. I also make increase with it, almost automatically, at will. Transferring is no longer the disagreeable, wasteful, and gummy job it used to be. By the use of the controller, bees are transferred from box hives almost as readily as artificial swarms are produced. As a feeder it has no equal. The apiarist can feed his bees at any time, night or day, as easily as he can feed his chickens or his horse. The feeder is always in place, does not have to be stored away and hunted up again when needed. It requires no attention, and is not in the way. It affords the most natural and efficient means of storing and caring for empty

ed between two hives, into a closed chamber. On top of this is seen a square piece of board, which is the cover to the feeder hole. This block is turned aside, and an inverted Mason jar is set in its place, thus completing the feeder.

The openings in the sides are closed as desired by metal or wooden slides that are pushed in at the main entrance, against the inner sides of the openings. On the right side is seen a perforated zinc slide closing this entrance. Fig. 2 shows the opposite side of the controller, with its entrances.

HOW TO ADJUST THE SWARM-CONTROLLER TO THE HIVE.

Remove the $\frac{3}{8}$ -inch cleat at the rear of a Danzenbaker bottom-board, thus making a new entrance. Place the hive-body on the bottom-board and fasten it. Apply the left side of the controller, as seen in Fig. 2, to this new entrance so that it will register with the openings in the side of the controller, and make it fast to the hive with two screws through the holding-cleat. It is fastened to only one hive, preferably to an empty one, which we call the "annex." The hive containing the bees to which this combination is to be joined is prepared in the same way by removing the $\frac{3}{8}$ -inch cleat at the rear of the bottom-board, making a new entrance at the rear of the hive. The annex is now set up against this hive so that the entrances coapt as before on the opposite side. The device, properly positioned between two hives, is seen in Fig. 3.

Here also may be seen on top of the controller two metal slides ready for use, and one provided with a Porter bee-escape used in transferring. Further back on top of controller is seen the cover to the feeder hole. The rear end of the controller is here closed with a movable shutter.

HOW TO PREVENT SWARMING.

The practical beekeeper endeavors to keep his colonies from swarming during the honey-flow. It is then, as a rule, that the swarming impulse develops. Congestion of the hive with bees and honey is probably the principal determining cause, as well as want of room and a crowded house. Before this state of affairs comes

Fig. 1.—Simmons device for controlling swarming.

combs and surplus honey ever devised, and is worth to any beekeeper, for this purpose alone, more than double its cost.

Its principal uses will be described in a series of articles, of which this is the first.

Fig. 1 shows the general form of construction. In plain words, it is a box with open ends, having a central transverse partition which divides it into two equal compartments. In each side there are two openings, $5 \times \frac{3}{4}$ in., which are the entrances into the hives on either side. The central partition lies transversely across the chamber between these two entrances on either side. The top is 16 in. long, and the bottom is 19 in., giving $1\frac{1}{2}$ in. at each end of the bottom as an alighting-board. The depth of the entrance is $1\frac{1}{2}$ inch. The left-hand entrance is closed with a shutter, converting this end, when adjust-

Fig. 2.—The other side of the device shown in Fig. 1.

Fig. 3.—The swarm-controlling device in position between the "annex" and a hive of bees.

about I attach the swarm-controller and annex, and make the bees work through the controller.

Referring to Fig. 3, the left hive is the annex, the right containing the bees. The annex is filled with empty combs or full sheets of foundation.

There is now a free passage from one hive to the other through the controller. At the rear it is through a closed chamber; in front, across the front *entrance*, or *vestibule*, from side to side. The bees immediately investigate this annex, and occupy it with a strong guard. They seem at once to regard it, from the arrangement of contiguity and ease of access as a part of their domicile. In very warm weather, instead of lying out they go over into the annex, where they find room and a natural resting-place. When desired, the original front entrances (now the auxiliary entrances at the extreme right and left of the combination) may be opened to give increased ventilation. Supers are provided early; and as the outside combs in the brood-nest become filled with honey and pollen I remove those and set them in the annex, placing a frame of foundation in the center of the brood-nest, after separating the combs, one for every such comb of honey removed. Building up these combs furnishes employment for a class of workers that probably have something to do with developing the swarming impulse when not gratified. These new combs give the queen added room for breeding. When the second super is well started, and the first is completed, I set it over on the annex. These combs in the annex and the superimposed boxes of honey increase the interest of the bees in this division of their house. There are, during the active season, a great number of workers whose wings become badly worn,

and they are no longer useful in the field, but make excellent guards. These old bees naturally retire to a place of least resistance, out of the way. This annex provides for them a place of refuge, where their presence is of value as guards, and their lives and usefulness are greatly prolonged. There may be conditions under which this method will not prevent swarming; but in my experience they are extremely rare, and not to be reckoned against the system when employed before the swarming impulse is developed.

Auburndale, Fla.

[In the May 1st issue Dr. Simmon will explain how he uses his controller to check the swarming impulse, when once it has been established, by using it to switch the bees into the "annex."—Ed.]

TENNESSEE BEEKEEPERS MEET WITH THE FRUITGROWERS AND NURSERYMEN

BY GEO. M. BENTLEY, STATE ENTOMOLOGIST

The Tennessee State Beekeepers' convention was held in Nashville on January 27, and the program carried out completely. There was a good attendance—larger than ever before. This was chiefly due to the convention being held in conjunction with the annual conventions of the fruitgrowers and nurserymen, and through the efforts of this office in advertising the meetings, not only throughout Tennessee but all over the South. The stereopticon lectures by Professor George DeMuth, of Washington, D. C., and Dr. J. S. Ward, of Nashville, were especially entertaining and instructive. Each of these lectures was illustrated by 100 or more perfect slides; and as the lecturers proceeded, every detail was plainly shown on the screen. It was decided that

Hogs pastured in a field of white sweet clover near Delmar, Iowa.

the association meet next year in conjunction with the fruitgrowers and nurserymen, and use every effort to increase the membership.

The legislature of 1911 appropriated \$1000 for apiary-inspection work in Tennessee. The past summer this work has been conducted in Middle and West Tennessee. The coming summer attention will be directed to East Tennessee. The survey of the bee interests in the State as gathered by the State Entomologist is being revised and greatly augmented.

Knoxville, Tenn.

[The Tennessee Association is doing some advanced work along the line of beekeeping, and other associations in the country may well afford to take notice. It is a splendid plan, in more ways than one, to hold the annual convention with the fruitgrowers. From the Secretary, J. M. Buchanan, we received a report of the election of officers which is as follows:

President, W. N. Joseph, Nashville; Vice-president, David Wauford, Alexandria; Secretary, J. M. Buchanan, Franklin.

In a newspaper clipping giving a report of the convention we note that Mr. Buchanan stated, in his address before the convention, that European foul brood exists in Shelby and Robertson counties, and that American foul brood, which is more prevalent, is found in Davidson, Williamson, Roane, and Hamilton counties. Other counties under investigation are Giles, Lawrence, and Montgomery.

The association has now something over eighty members, between fifty and sixty of which were present. There are said to be 36,000 beekeepers in Tennessee. The annual value of the honey crop in the State is nearly \$250,000.—ED.]

HOW TO GET A STAND OF SWEET CLOVER

BY FRANK COVERDALE

After reading what Dr. Miller has to say, page 48 of the booklet "The Truth About Sweet Clover," I feared that he had not been reading my articles in the farm papers, for he says he is not able to get a good stand. Now, a great deal depends upon methods used and the conditions of the soil in which the seed is sown. I have made a specialty of investigations along this line, and making experiments under every conceivable condition: and I have found that it is so easy to get a perfect stand that no one need make a failure. It is quite plain to me that neither Dr. Miller's soil nor his neighbor's has any sweet-clover bacteria in it; and, for that reason, many of the sweet-clover plants will fail to grow nodules on the roots, but will turn yellow and die. If this same soil had been rich in plant food, every one of the sweet-clover plants would have formed nodules and made a perfect stand of luxuriant clover.

Nine years ago I sowed a sixty-acre field to white sweet clover, and also a forty-acre field. Although the plants started, not a single one lived until winter, and the whole undertaking was a failure because of the poor and impoverished condition of the soil. Many others around here lost their seed in the same way. The tables have turned, however, for we are now securing perfect stands of this legume, as shown by the picture of one of my neighbor's fields. His hogs enjoy a continued feast, and they keep it down to about six inches high by continual browsing. My neighbor has a field of alfalfa adjoining this, and he has been changing the hogs from one to the other, but he is much better pleased with

the results from the sweet clover, as it is so much more hardy. He has now bought seed to change his alfalfa-field into sweet clover, as the alfalfa won't stand being pastured. A few more farmers in this neighborhood have secured seed, and will have hog-pastures just like this one.

The field shown is identical with our own, especially our hog-pasture. I have come to the conclusion that every farmer can and should have a hog-pasture like it. Every one around here who has come to my knowledge is very enthusiastic over the success, and is securing new supplies of seed to be sown next spring. This fact speaks louder than any other. My seed is all sold.

Delmar, Iowa.

THE EASTERN NEW YORK BEEKEEPERS' MEETING

BY S. DAVENPORT, SECRETARY.

The Eastern New York Beekeepers' Association held its fourth annual convention Dec. 21, in the City Hall, Albany. Owing to unfavorable circumstances only a short notice could be given, and consequently there was a more limited attendance than usual, only about thirty beekeepers being present.

President W. D. Wright, of Altamont, presided.

The proceedings consisted mostly of routine business and the consideration of technical questions pertaining to beekeeping.

The members reported the past season as the poorest in many years. The production of honey was less than half of an average crop; but with the optimism characteristic of beekeepers, all hold bright hopes for the future.

The secretary's report showed a list of 103 members since the organization of the association four years ago. The treasurer reported a neat balance on hand.

The president, in his address, reviewed the condition of the industry, referring to the very unfavorable season and the shortage of the honey crop, and noting that a material advance in prices had resulted, which, it was hoped, might be maintained in the future. He called attention to the action of the National Beekeepers' Association in reorganizing that body and adopting a new constitution for the working of the association on a new and entirely different plan.

Much consideration was given to this subject, and many expressions of disapproval were offered. It was decided unanimously to take a vote by mail of all the members on the question: Shall we renew our membership in the National Association under the provisions of the new constitution?

The annual election was held, and resulted in the reelection of the entire board of officers as follows: President, W. D. Wright, of Altamont; First Vice-president, A. Johnson, Schoharie; Second Vice-president, C. W. Hays, Brookview; Secretary, S. Davenport,

Indian Fields; Treasurer, M. A. Kingman, East Greenbush.

This will make Mr. Wright's fifth term as president.

A communication from the Hon. R. A. Pearson, State Commissioner of Agriculture, was read, requesting the appointment of a delegate to represent the association at the annual meeting of the New York State Agricultural Society. S. Davenport was elected as such delegate.

A communication to the State College of Agriculture had been directed to be made, requesting that experiments be made along the line of reducing the length of the corolla of the red-clover blossom, to enable the honeybee to gather the nectar from it. C. B. Loomis, of East Greenbush, presented a communication on the subject from Prof. H. W. Webber, of the State Agricultural College.

C. B. Loomis presented for examination and consideration a sample copy of a writing-pad for the use of schoolchildren, having appropriate illustrations of the honeybee, queen, and drone, and a descriptive article on the honeybee and the desirability of honey as a food. This pad is issued by the New York State Association of Beekeepers' Societies with the object of advertising honey and increasing the sale of it.

A proposition to establish a honey exchange at Albany, for the purpose of disposing of the honey crop of members of the association, was discussed, and a committee of six appointed to investigate, consider, and report.

This gathering of beekeepers proved to be one of the most satisfactory conventions ever held by the association.

Indian Fields, N. Y.

HATCHING OF EGGS DEPENDS UPON CONDITIONS WHICH SUIT THE BEES

BY M. Y. CALCUTT.

I notice that Mr. Wm. L. Couper, p. 660, Nov. 1, takes issue with the editor, and inclines toward Dr. Miller, that a queen very seldom lays eggs that will not hatch. I also am inclined to think that the doctor is right in this respect. I think Mr. Couper must have overlooked the real reason why the eggs mentioned in his article were not hatched by the bees. My experience is from long study with one of the best observation hives which I have seen. The hive is constructed so as to take four single frames, one above the other, having glass on both sides of the frames, with a single bee space between comb and glass, the hive doors opening on the north and south sides so as to let the sun shine through the comb when desired. By throwing a dark cover over myself I am enabled to get a fine view from the north side, with the sun shining through from the south, especially when I have a new white wax comb.

I have found that eggs do not hatch until the bees want them hatched; and when

things are not just to their liking they will leave them for days or until conditions are just right to suit their fancy; and if conditions remain unfavorable, they will, within a reasonable time, remove the eggs and eat them. The mere fact that Mr. Couper removed these frames to another hive does not in any way prove to me that there was any thing wrong with the eggs, but that the conditions in the second hive were similar to those in the first, and therefore the bees would not hatch them. I have tried some interesting experiments along this line. I will give the result of one.

As there was no honey coming in from the natural flow I placed a division-board feeder in the fourth section of the hive, giving a pint of syrup at a feed. After the queen had filled the first comb full of eggs she moved to the second frame. The bees, meanwhile, had been at work drawing this comb down and storing syrup. After the queen had deposited a large number of eggs in this comb I stopped feeding, and watched results. The bees ceased to draw down comb, and commenced to remove the eggs laid by the queen. They would destroy them as fast as the queen laid them. After they had destroyed all the eggs but about as many as would go in a $2\frac{1}{2}$ -inch circle I again commenced feeding. These eggs had lain in the cells between four and seven days. The bees now began to take care of them and hatched them. Now, Mr. Editor, if I had not tried feeding again, these eggs would not have hatched, but would have been destroyed; but when the conditions were right to suit them they hatched them, and not before. A queen will lay sometimes whether conditions are right or wrong. The bees seem to determine these conditions to a great extent. This hive was not short of supplies in the comb, having plenty of sealed honey.

BEES TRANSFERRING THE EGGS OF THE QUEEN.

Can or do the bees sometimes carry eggs and place them in the cells? Yes. I caged a queen for four days in a hive that I had prepared with starters before shaking again on full sheets of foundation—a case of American foul brood. The bees drew down the starters and carried the eggs from the queen-cage, taking them from the wire where the queen had deposited them in bunches, and distributed them as nicely as the queen would have done. This can not be disputed.

WHY BEES SLEEP IN CELLS CONTAINING EGGS.

Mr. Arthur C. Miller, page 663, Nov. 1, says, "Bees sleep, and do a lot of it." Let us grant it. Does it follow that they crawl into a cell simply to sleep? I doubt this statement. And, again, "Their presence has nothing to do with the hatching of the egg." Is this true? I wonder, Mr. Editor, that they persist in sleeping in the cells that contain eggs. Why not sleep in cells that have no eggs? Has locality any thing to do with this? I have watched this very

closely, and I have failed to note an egg hatching in a cell that a bee had not spent considerable time in, and I also note that they do not spend any time *sleeping* in a cell of new comb unless there are eggs in it. As to whether a bee's head ever touches an egg in the cell I can not say. I have made my observations with a powerful magnifying-glass, and the sun shining through the comb; but I have invariably found that there was a bee in the cell on the opposite side. I have never been able to look through a comb and tell how close a bee's head was to an egg. If I could look between the head and the egg I might be able to determine this point; but I know of no way that one can look through a bee in a cell to determine how close its head is to an egg, nor to reverse it and look through the bottom of an empty cell so as to see how close the egg on the other side is to the head of the bee.

PACKING POLLEN IN THE CELLS.

Let me add to what Mr. Miller has to say about bees packing pollen in the cells, that never, so far as my observation has gone, do the bees that bring the pollen into the hive, pack it into the cells, although they put the little pellets in the cells direct from their pollen-baskets. Other bees do the packing of the pellets.

I should like to have Mr. Miller explain to me why the pollen-bearers go through the crazy antics that they perform before and after depositing their load of pollen in the cell.

ECONOMY IN USE OF FOUNDATION WHEN THE SUPPLY IS LIMITED.

I have a scheme for nice straight all-worker comb when I am short of foundation, and can not give a whole sheet. I wire all my frames, then cut four strips as wide as I can afford to give, fastening to the top bar and sealing two of them to the end bars, dividing the distance between these with the other two. I then fill in with short pieces of starters on the top bar. The bees will draw down from the top starters and connect with the upright strips, bringing the whole together in a beautiful straight worker comb, and they will not build drone-storage comb between these strips.

Seattle, Wash.

The Bee.

BY N. W. SAUNDERS.

God, our precious loving savior,
Sendeth down the rain and shower,
Then the flower; then the honey-bee
That flies from flower to flower,
And hangs around the leaf and bower,
Seems like God's precious promises
He offers without price
If we will but accept.
Yet we selfish creatures sell the honey
For the sake of sordid money.
But, thanks to God for all we see,
Especially the honey-bee.

Heads of Grain from Different Fields

Notice to Iowa Beekeepers

The beekeepers of Fort Dodge and vicinity are trying to organize a beekeepers' association for the State of Iowa, under the auspices of the National Beekeepers' Association. We find, in looking over Bureau of Entomology Circular No. 138 of bee diseases, that there have been reported in Iowa up to May 10, 1911, seventeen counties that have American foul brood, and sixteen counties more in which it is suspected; European foul brood in four counties, and one suspected; and it is scattered from one side of the State to the other, as you will see if you check the counties as I have; and you will see we have enough foul brood to infect the entire State, even if this is all there is in it. For the benefit of those who have not received Circular No. 138 I will give a list of the counties that have the malady.

AMERICAN FOUL BROOD.		EUROPEAN.
<i>Present.</i>	<i>Suspected.</i>	<i>Present.</i>
Allamakee,	Appanoose,	Guthrie,
Butler,	Buena Vista,	Johnson,
Carroll,	Cherokee,	Linn,
Clayton,	Davis,	Muscatine.
Clinton,	Ida,	
Des Moines,	Marshall,	<i>Suspected.</i>
Dickinson,	Monona,	Scott.
Fayette,	Monroe,	
Fremont,	Montgomery,	
Hardin,	Page,	
Linn,	Plymouth,	
Lyon,	Polk,	
Mills,	Scott,	
Pottawattamie,	Sioux,	
Sac,	Taylor,	
Story,	Vanburen.	
Woodbury.		

It seems to me that it is high time for the Iowa beekeeper to wake up and get busy. We must have inspectors in the field. In looking over the 42d Annual Report of the National Beekeepers' Association I find that they have 92 members in Iowa. What are you doing? Are you waiting for Messiah to rise up among you to carry the cross? The writer has been interested in the bee business only about twenty months; but he can see what the outcome will be if we do not get busy. We must get an appropriation, and that means delegates to the legislature. We have the law; but of what use is it with no funds to do the work? Are we going to fold our arms and let this malady run rampant through our State? We have a big job on our hands now, and it will be larger next year. Iowa beekeepers, don't stop and think, but think on the go, and don't think too long, and don't think the other fellow will do the work and you get the benefit. It may take a few sections of honey to defray the expenses now; but let it go and it means sections, supers, hives, bees, and all.

Mr. Frank C. Pellett, of Atlantic, made a request, through the columns of GLEANINGS, to the Iowa beekeepers to meet at Des Moines. A few responded, but not enough to organize. If we do not wake up now, our slumbers will be broken by that awful smell that comes from American foul brood. When I was at the National convention at Minneapolis last August I examined some American foul brood, and I imagined I could smell it on my hands all the afternoon, although I did not touch it at all.

I heard there was or has been a beekeepers' association in the west part of this State. If there is, we shall be glad to join it. I have not been able to locate it as yet. If any one can I will thank him if he will send me the address of the secretary; and if it is alive and in working order, I for one will join it and do what I can, and I believe I can get at least a dozen more to join. If we haven't an association in Iowa I should be glad to have all the beekeepers in this State who read this to write me and state their views, and also state what they are willing to do. If a few of us have to put our gloves and vells on and fight this appropriation through we shall have a hard time. Let all of us light up our smokers and get a rousing association in Iowa. If you have a representative or senator near you, or one you are acquainted with, go after him and the work will be easy.

Fort Dodge, Ia.

E. E. TOWNSEND.

[The following will show that a work has been started, at least.—ED.]

Iowa Has a Beekeepers' Association

On December 29 the Tri-state Beekeepers' Association met in Sioux City, and at that meeting the Iowa delegation organized the Iowa State Beekeepers' Association, with W. P. Southworth, of Salix, as president, C. L. Penny, of Lemars, secretary and treasurer. Three vice-presidents were chosen to boost the organization in their districts—Frank C. Pellett, Atlantic; Frank Coverdale, Delmar; and J. L. Strong, Clarinda.

As a committee on program for the next meeting, the following were named: C. L. Penny, J. B. Espy, R. A. Morgan.

Iowa needs the Association, and the Official Board will expect the enthusiastic co-operation of every beekeeper in the State, and each one is urged to send in his name and membership dues at once to the secretary, C. L. Penny, Lemars.

To be in harmony with the new constitution of the National Beekeepers' Association, when it is adopted, the membership dues are fixed at \$1.50 per year. Some may say that their dues are paid up in the National, and, therefore, they will delay sending their dues in to the State Association. Please do not do this, but send in your dues at once, and your membership in the National will be extended.

The new Association needs funds with which to begin work at once. The first business in hand will be to arrange for a big convention to be held at a time that will be most convenient for the largest number of beekeepers, when the organization will be perfected, and immediate steps will be taken to secure legislation to assist in checking the spread of bee diseases in the State.

No State in the Union can produce better honey than Iowa; and by mutual assistance the beekeepers can greatly increase their yields and improve market conditions.

Let every one interested in bee culture join the big cluster at once, by sending in his name and any suggestion that he has to offer.

Salix, Iowa.

W. P. SOUTHWORTH, Pres.

Clipped Queens a Nuisance

Mr. Arthur C. Miller's article, page 755, Dec. 15, on clipped versus unclipped queens, also the footnote asking for reports on this subject, prompts me to make reply. For the past forty years I have kept bees more or less. My home was in Northern Vermont until 1904, when I sold out and came to this coast. For about a year I was without bees; but being a wild-bee hunter I soon had some. This was in the suburbs of Portland, Oregon. At one time I bought 7 stands. One being queenless, I broke it up. I sold 11 colonies the following spring, so that my present yard of 78 colonies is practically all from the woods. When near Portland, being confined to a city lot, with tall fir-trees on one side and choice fruit-trees on the other, I resorted to clipping. I had tried it twice in Vermont, and both times had condemned it; but as location makes a difference in some respects, I tried clipping here for the third time. I saw no difference in the work of the queens, and never did in Vermont; but trouble came when swarming came. The swarms would generally settle. The limbs had to be broken off my neighbors' fruit-trees, or the tall firs had to be climbed just the same. The swarms were hived in various ways, as deemed best, sometimes on the returning plan. In case of others, the queen was placed among the bees, where they had settled. But the great majority of the swarms, after being hived a short time, would begin to return to the parent hive. On examination a ball of bees would be found on the bottom-board, surrounding the poor clipped queen. The bees seemed to know that the queen was maimed and could not fulfill her natural office, viz., to depart with the swarm to a new locality, and so they would not tolerate her. If a swarm returned to the parent hive before I could find the clipped queen, or in my absence, it meant sure death to return her. If I could find the queen quickly, and replace her in the cluster about as soon as it began to form, she would be received all right. But bees are hard to deceive, so I clip no more.

I lost all of my fine yellow queens which I had reared with great care the year before, and was en-

tirely out of the stock solely because of clipping. A clipped queen in a hive is a nuisance, because she can not help herself. If in manipulating the hive she falls to the ground, she can not rise and return. I have seen them under the bottom-board with a cluster of bees that had to be returned several times before she could be captured, because she would crawl off in the grass. When a swarm issues I always look for the queen in front of the hive. As a great many, although their wings are perfect, can not fly, they keep trying to do so, and crawl up on the grass until their weight bends it down. Thus they keep well up on the grass, and are easily found. The clipped queen simply crawls, and thus goes lower and lower in the grass, and is hard to find. An unclipped queen can be caged for a long time if the swarm does not return; and when it does she can be placed among the bees, and no harm follows. If the swarm returns she can be returned also, and will come out again next day with the swarm. Very few unclipped queens are lost in swarming except by mixing. I have had scarcely any bees leave me at swarming time. If I am absent they generally hang until I return.

I do not say that there was this wholesale slaughter of clipped queens in Vermont, although I lost some. It was a general superseding after clipping, not always immediately, but pretty sure to come. Treading on clipped queens while looking for them in the grass is another serious objection. I want my queens to be able to fly. Clipping is unnatural; and it has been my experience that it does more harm than good. I am a follower of nature, and am growing more confirmed in it.

Yacott, Wash., Jan. 1. H. E. HARRINGTON.

Shipping Bees to South America

Will you kindly furnish me information as to how to pack bees? When is the best time to leave with them from New York? Please give all the information necessary for the trip from here to South America.

Nashville, Tenn., Jan. 6.

F. L. GLISSON.

[We have never shipped any bees during cold weather, and therefore can not give you any information based on experience. Bees, however, have been shipped while it was quite cold. They have been hauled by sleds from one apiary to another; but in that case it is usually advisable to put them in some cellar rather than out on their summer stands, as the excitement caused by moving causes the cluster to expand too much, and the bees become chilled, causing many of them to die. It would be our judgment that it would not be practicable to ship bees to New York until along in the spring, when the weather begins to warm up. If you could once get them aboard the ship, we do not think there would be any trouble about sending them at any time of year.]

If you feel that you must ship the bees during midwinter in order to get them to South America in time for a flow of honey, we would advise you to have the frames securely fastened in the hive, using wired combs in any case, and screen the hive, top and bottom. But while the bees are being shipped by rail to New York in cold weather, it is advisable to secure the cover close to the screen. In other words, shut off the top and bottom ventilation, leaving only that which would be provided by the entrance, which should also be screened. The hives should be put in a car and loaded on to straw in such a way that the frames will be parallel with the track. It will be very necessary to see that the hives are securely fastened down, because, if the cars are bumped back and forth, the hives will be broken open and bees liberated. If you have more hives than can be accommodated on the bottom of the car, you can arrange to put series of planking or boarding above the hives that are already on the bottom, and put another tier above. In that case, leave about a foot or more of space between the two tiers of hives.

Taking it all in all, we would hardly dare risk the experiment of shipping a carload of bees during the dead of winter to New York. They might go through in good order, and they might not.—Ed.]

Regarding the Change of the California Foul-brood Law

P. C. Chadwick, of Redlands, Cal., page 39, Jan. 15, says that every one with whom he has talked or corresponded agrees with him that a more strin-

gent foul-brood law would be an excellent thing. I wonder whether Mr. Chadwick is familiar with the law of California, or whether it is a case of inspectors not doing their duty. The county board of supervisors of this State now appoints the inspectors, and every county has the right of an inspector upon a presentation of a petition. Generally the one they recommend is appointed. This same official can be removed by the same proceedings. Furthermore, most of the counties in Southern California have county ordinances for the further protection of the bee industry. Under the present law the beekeepers have the situation in their own hands.

If a State inspector can do better, let us have one by all means; but we must consider that California is a large State, and his doing all the inspection would be impossible. So it is a question as to whether we would not have the same inspectors after all, they holding the office as deputies. There is but one question in my mind: Do we want the governor to appoint our inspector, or shall we name our own as the law now reads? The State inspector, too, would be harder to reach than the board of supervisors.

El Centro, Cal., Jan. 26.

A. F. WAGNER.

Paper for Wrapping Hives in the Spring

Mr. E. D. Townsend:—Having read your books, I notice you use white felt paper for protecting hives in the spring. Can you tell me the trade name of this paper, and where I can obtain it? The only samples I have obtained are asbestos and deadening felt, and neither one seems right.

East Syracuse, N. Y.

F. W. LESSER.

[Mr. Townsend replies:]

We too have had trouble of late to get the same sheathing we bought five or six years ago, as the manufacturers seem to have adopted something besides the spruce that was formerly used in the manufacture of this white paper. Hereafter we shall use a tarred felt paper for wrapping our hives for spring protection. If the cover of a ten-frame hive is removed, and paper, although only 32 inches wide, is put next to the bees it will come within 2 inches of the bottom of the hive. On an eight-frame hive it will be about the desired width. If four lath are used in fastening the paper at the bottom, as we advise, two of them being 20 inches long, and the other two the length of the width of the hive, and a nice job of wrapping is done, so that the paper is not torn, and if there are no wrinkles at the bottom, no heat to speak of can escape from a colony except at the entrance. On account of the molding of the handle extending at each end of the hive, we fold the paper at those corners of the hive. In this way an allowance can be made for this projection when folding.

We cut our papers 38 in. long, on account of the hand grips taking some extra paper. Otherwise 36 in. would be the right length to make the end and sides come even at the bottoms.

Now about the paper to use. If you will turn to Sears, Roebuck & Company's fall and winter catalog, page 600, bottom of first column, you will find three weights of tarred felt. No. 1 has 250, No. 2 has 400, and No. 3 has 500 square feet to the roll. The price a roll, 90 cents, is the same for any one of the three kinds. We have so far used the No. 2 felt, but will try some of the No. 3 this year. If the No. 3 is tough enough to stand putting on without tearing, it will be warm enough, without a doubt.

After this severe winter, many unprotected bees will be dead. Others will be between medium and good. It will be desirable next spring to foster these "weaklings," and papering will be found the most simple method, and the equal of any packing for spring protection.

Remus, Mich.

E. D. TOWNSEND.

Annual Meeting of the Oklahoma Beekeepers' Association, Stillwater, Jan. 18, 1912

There were present the smallest number of beekeepers that have ever attended a meeting of the Association; but nearly every number on the program was filled, either by the party being present or sending in his paper.

It was voted not to become a branch of the National Association at present, and the membership fee was reduced to 50 cents. The following resolutions were adopted:

Be it resolved by the Oklahoma Beekeepers' Association, that the A. and M. College and Experi-

ment Station be requested to carry on more experiments along apicultural lines, to determine the best race of bees, the most useful hive for the farmer beekeeper, the best manner of feeding bees, and also to experiment with different honey-plants.

We also request that an apiary be established at the College, and some help by lectures and exhibits on some of the future demonstration trains be given.

N. FRED GARDINER, Pres., Geary,
GEO. H. COULSON, Vice-pres., Cherokee,
G. C. BOARDMAN, Sec., Shawnee,
G. E. LEMON, Treas., Nash.

Ten Questions and Answers

1. In a bee-cellar, where should the thermometer be placed—at the bottom, top, or middle, to mark the required temperature of 42°?
2. In making nuclei, what is the best way to build them up to become strong colonies?
3. Do you approve of metal sheets for covers to hives? I have found that they retain moisture in great drops on the under side; or is there a way to overcome the moisture?
4. Is it all right to breed virgin queens to drones of the same hive?
5. What is the great objection to natural swarming?
6. Do the Italian bees excel all other species in working on red clover?
7. Do bees work continually, or take a rest after each load?
8. Just before uniting two colonies by alternating their combs, should they be smoked, and the selected queen caged and destroyed?
9. Is ripe alsike clover injurious as a feed for cattle because of danger of poison from the seed?
10. Which is the better to use for coating the inside of wooden feeders—paraffin or linseed oil?

Slate River, Ont., Jan. 20. J. M. MUNRO.

[1. We usually hang the thermometer in the middle of the cellar about half way between the lowest and highest hive of bees. In a good bee-cellar you are not likely to find as much difference in temperature between the floor and the ceiling as in a room where there is artificial heat, for instance, and where there is outside exposure.

2. We regard the Alexander plan for making increase as rather the best, all things considered; for the weak nuclei, being kept over the strong colony, have a better chance to keep warm and to breed up properly.

3. We do not approve of sheets of metal for covers of hives unless there is wood underneath. If we understand the type of covers you refer to, there is no wood lining. In that case you should use a thin cover underneath, known as a super cover.

4. If inbreeding were kept up very long, it is likely that the stock would degenerate. But there is not much danger of this; for unless you are in an isolated locality several miles from bees in beehives, etc., you can not be sure that your virgins are mating with drones from the same colony they were reared in. Even under the conditions named you have to keep drone-guards over all other colonies if you wish to prevent the virgins from mating with other drones.

5. A certain amount of natural swarming is not objectionable in the least if some increase is wanted any way, and if the swarming is not kept up to such an extent that the strength of the colony is reduced so that less surplus honey is produced. Some strains of bees will swarm excessively. Some of the largest producers that we have ever known have said that they do not object to natural swarming; but they do object, of course, to after-swarming. Where the bees want to swarm, however, as soon as the colony becomes strong enough to work well in the supers, so that super work is retarded, then the trouble begins.

6. Some Italians excel all other bees in working on red clover; but it would not be true to say that all Italians do.

7. It is impossible to give a definite answer to this question, as it is likely that bees rest more or less, although we are not quite ready to believe that they rest after every trip. At a time when one can hear above all else the roar of bees working feverishly on the flowers during a good flow of honey, it seems impossible that there could be very much resting going on during the height of the work of the day.

8. We do not advise the plan of uniting that you

refer to here. It is better to have the bees unite very slowly, so that they hardly know a change has taken place. Placing one colony over another with a newspaper between is a good way. In either case it is well to kill the inferior queen first and then cage the other.

9. We have never heard that ripe alsike clover is injurious to cattle. We can not say positively; but we doubt whether there is much foundation for such a theory. If any of our readers have reason to think otherwise we should be glad to have them report.

10. Paraffin is rather better for coating the inside of feeders, as it has more body, and is more likely to prevent leaks.—ED.]

No Difference in Laying, Whether Queens are Clipped or Not

For the last five years I have clipped every laying queen I owned, and will continue to do so as long as the results are as satisfactory as they have been. I do not see the slightest difference between the laying of clipped and unclipped queens, as Arthur C. Miller outlines, nor do I see that they are handicapped in any way, for I have had clipped queens reach the age of four years. There is only one season of the year when I hesitate to perform the operation, and that is from the middle of February to the first week in March (that is, here in the South), for at that time there are so many old nursing bees with a very cranky disposition; and with the least indication that the queen is not acting normally they will attempt to ball her.

Elmendorf, Texas, Jan. 19. ALFRED L. HARTL.

Buckwheat Yielding Differently on Clay and Sandy Soil

Regarding the article on p. 713, Dec. 1, "Why Buckwheat Yields only in the Morning," if I am not mistaken it usually yields honey nearly or quite all day on sandy soil; but on clay or even clay loam, it seldom yields in the afternoon. The quality, too, is better on sandy soil.

From fifteen to twenty years ago there was a good deal of buckwheat raised near my yard in the northern part of Sauk County, Wisconsin, and I often took as much as 100 pounds of nearly pure buckwheat honey (extracted) from a single colony. I think some years the yard averaged that much. We get but little there now.

Veedom, Wis.

E. M. HAYES.

Information Wanted on Producing Honey in Diseased Apiaries

There are many articles on curing foul brood, but only occasionally one on raising honey where the disease exists. We need good articles on systems of keeping bees healthy and raising extracted honey where the disease does exist. It is done. There are beekeepers in Utah who raise it by the carload in locations one-fourth to a half diseased.

North Yakima, Wash.

V. V. DEXTER.

[This is an important question; for with European foul brood especially, it is almost impossible to get entirely rid of the disease at once; and if it gets into the locality, it is bound to keep cropping out to some extent for several years, although it can be kept well under control. We shall be glad to have our readers give us the benefit of their experience along this line.—ED.]

How Could Bees Separate Water from Syrup so Quickly?

In my article for Dec. 1, p. 717, I wrote about "little drops falling like rain." Dr. Miller and the editor, p. 4, Jan. 1, joined in saying that it was "water separated by the bees from the syrup." I do not care to question authority as good as this, but at the same time it gives rise to several questions in my mind that I should like to see answered for the good of the readers.

1. How long a time is required after a bee has taken up the syrup before it will be able to throw off the water? Those drops were falling all the way between the tub where the bees were feeding and the hives, six or eight rods away, but to a great extent near the tub, or before the bees could rise over the brim.

2. Was this water separated from the syrup while being taken, or after it had entered the honey sac?

3. We often notice after a rain during a flow of honey that nectar is very much thinner than at other times. Why does this filter not work at such times rather than force the bees to carry to the hives a large surplus of water that must be evaporated later?

4. In giving bees a rough handling until they have gorged themselves with honey, how often do we find them regurgitating it over themselves, forming a sticky mass?

This process, I understand, represents an abnormal condition; but so is feeding from a tub unusual. Furthermore, on the grass all around the tub were scores of bees that I supposed were reclaiming the sweets that had been lost. I may be mistaken in this, but will try an experiment in the spring to make sure. I am satisfied for the present with what became of my 500 pounds of sugar. Moistened sugar for stimulative purposes and heavy syrup fed quickly for winter stores (both fed in the hive) suit me; and if I should try feeding in the open air again it would be with moistened sugar spread over a large surface.

Hartford, Ct.

A. W. YATES.

[1. The bees we have observed, eject the water ten or twenty feet from the ground after they arise from the outdoor feeder. Sometimes the spray is shot out when the bees are forty to fifty feet from the point of starting.

2. We do not know how the water is separated. The sweetened water they take up from the feeders may go into the honey sac or stomach, and the excess of water pass through the alimentary canal, and finally out at the anal opening; or the excess of water may be regurgitated and discharged from the mouth. It will be very difficult to determine just how the bees do it; but it is remarkable that such a fine spray should be shot out immediately after taking flight.

3. We do not know.

4. We have never noticed the bees regurgitating the honey over themselves when roughly handled; or, rather, we should say, we have never handled them so roughly that they have ever done this. We were not aware that rough handling of any sort would cause them to regurgitate the contents of their honey sacs or stomachs on themselves.

Referring to your last paragraph, we have no absolute means of knowing whether the spray discharged by the bees while in the air is water free from saccharine matter or sweetened water that is an excess of what they can carry. As the bees shoot out this spray when gathering nectar from the flowers as well as from feeders it would hardly seem to us that nature would be so wasteful that she would throw away sweetened water or nectar. In other words, it is our opinion that a bee is an economical machine. The principle of the survival of the fittest has made it so, apparently.

A. I. Root, some years ago, collected the spray that the bees shot out when they took wing while they were working on the spider plant. This spray was caught on dinner plates; and, so far as he could determine at the time, it was nothing but water, while the nectar from the spider plant, which he gathered with a tiny spoon, was distinctly sweet. Last fall we gathered on our hands some of the spray the bees shot out. On tasting it, it seemed to be nothing but water. However, it *may* have contained some saccharine matter. This is a matter that will have to be worked out by other observers. At all events, the spray such as we saw was thrown over the leaves and shrubbery near the outdoor feeder. The fact that our bees did not go after this after the feeders were emptied, and the further fact that it was evaporated without leaving a deposit, would seem to indicate that it was only water.

The bees that you found on the grass around the tub, we should be inclined to think, were those that had overgorged themselves and were unable then to take wing. Years ago, when our bees worked on the spider plant that gave such copious quantities of nectar, some bees would take such big drinks that they would drop down on the ground, apparently because they were overloaded. Presently they would take wing and away they would go.—Ed.]

Bees Eject Water when Fed Maple Sap

I have supposed or taken it for granted that every one knew that bees eject water when carry-

ing very thin nectar. Chip a maple, blackwalnut, or any tree that has a sweet sap, or give bees water slightly sweetened, and stand between them and the sun while they are carrying it home, and you can very distinctly see them eject water.

MOTHER AND DAUGHTER TAKING TURNS.

I raise my best queens from an old queen when I put her off by herself with a few bees and a single frame of brood, and let the bees supersede her. For some time the mother and daughter will occupy the same comb—the former laying once in a while an egg, while the latter will work very industriously laying eggs. I usually find them about two inches apart, and they appear to keep about that distance habitually.

THREE-WHEELED CART.

I do not like a wheelbarrow for handling honey nor for any other purpose about a beeyard. I use a three-wheeled cart with springs. I had it made at South Bend, Ind., and shipped to me as freight.

MOTHS IN COLORADO.

Don't you let them make you believe that bee-moths are unknown in Colorado—both kinds too. Just lease a ranch to some Easterner who thinks there are none, and by the end of the season you will be able to find plenty.

Carlton, Col., Feb. 5.

JAMES H. WING.

Production of Extracted Honey Much More Profitable than Comb

Referring to the editorial, page 35, January 15, I will say that it does not pay us to ship any comb honey to market, except the fancy and No. 1 white. At the same time, there are so many unfinished sections that have cost us about as much to produce as the good grade that the profit in comb honey is almost wiped out, since we are obliged to accept practically extracted-honey prices for these culls. When it comes to dollars and cents, extracted honey has comb honey beat a mile. We can produce almost 2½ pounds of extracted honey to one of comb. In this country we are just finding that extracted honey is much more profitable.

WINFIELD MARTIN.

Dampening 500 Sections Without Swelling the Wood

Remove the boards on the top side of the crate holding the sections and gently shake the loose sections end down until all of the V grooves are opposite and even. Drive two long sticks as wedges down to the bottom of the crate on one side so that the faces of the sections are tightly wedged together, and no water can reach them. Pick up the crate endwise and immerse it in a tub of water. The water will run through the open grooves, wetting them thoroughly, leaving the surfaces dry. Only one immersion is necessary, and the crate should be placed so as to drain at once. If kept covered the sections will stay damp all day, even in a dry climate.

L. C. CLARK.

Honey Cures Sick-headache

I have been informed by Captain Geo. H. Whiteside, a very prominent citizen of Apalachicola, also manufacturer of ice there, that he has been cured of sick-headache by eating honey twice a day. His headache was so severe that he had to go to bed, sometimes for several days. You may rest assured that this comes from a man who stands high among the people of this State, and from one who is a Christian gentleman,

POULTRY DEPARTMENT

A. I. Root

STILL ANOTHER "BIG DISCOVERY;" HOW TO "GROW" YOUR OWN BUTTER ("AS WELL AS EGGS") IN YOUR OWN BACK YARD.

Our friend Philo certainly made a big stroke in introducing a short cut between "producer and consumer" when he made "a little poultry" in the back yard so much the fashion; and in spite of his fearful exaggeration at times, I think we can give him a vote of thanks; but I presume it never entered his mind that his "system" would give *butter* as well as *eggs*. Well, just listen. Mrs. Root wanted a hen for dinner; and as the Leghorn yard contains the oldest hens I went to this yard after dark and sampled a dozen hens by feeling of their pelvic bones to see which were the layers, until I found one very fat and plump, with the said bones very near together; and as a further precaution I shut her up alone for a week; but, as I expected, she never laid an egg. When she was killed there were no eggs anywhere near maturity; but she was literally a great lump of fat. When "tried out" there was over a pound of nice yellow "chicken oil." I suggested using it for butter; and by salting to taste I find it suits me even better than the butter that now costs us 50 cts. at our grocers. In consequence of the recent high prices for butter, many are using cotton-seed oil, others oleo, and Terry uses olive oil, even if it does cost away up, because he thinks it even more wholesome than cows' butter. Now, why in the world can we not utilize this chicken fat, especially when all we can get in the market is about 15 cts. per lb. for our fat chickens—sometimes a good deal less than that? Once more, we talk about the high price of grain. Isn't there money in feeding grain to chickens when, by using this fat in place of butter, it nets you 50 cts. per lb. or more? Once more, where we keep feed right before our chickens, as I do (in galvanized tubs hung from the roof), there will be now and then a hen, even with the Leghorns, that gets too fat. When this occurs, just sort out the suspected drones, as I have outlined, and make them take the place of butter. By the way, every little while somebody wants my opinion of the "Potter system." This system is a *help*, as I have outlined; but I very strongly object to the way in which Potter does business. The price for his little book is an outrage. His secret has been published over and over, and his requiring a signed pledge "not to divulge," etc., is ridiculous. I have two or more copies of the book; and when I sent the money for the book, but *refused* to sign my name to the pledge of secrecy, he or they signed my name to the pledge without any authority at all from me. What do you think of such a way of doing business? Finally, the discovery is *not* Potter's at all. It is simply the *Hogan* \$10.00 secret of years ago. Never mind the secret or secrets; let

us all get to work and grow our own butter in the back yard—at least until butter gets down a little from off its present "high stilts."

INFERTILE EGGS, AND HOW MUCH HAS THE INCUBATOR TO DO WITH IT?

Feb. 9, at ten o'clock A.M., I put 63 duck eggs into the incubator; and finding a sitting hen when gathering the eggs, at dusk, I took 13 eggs out of the incubator and placed them under the hen. I did this to satisfy myself in regard to several matters pertaining to incubation. Well, after six days I tested all the eggs, and, to my great surprise, I found ten infertile ones out of the fifty in the incubator, and not a single one under the *sitting* hen. Every egg of her 13 showed plain and clear marks of fertility. What have incubator manufacturers to say to this? So far as I can remember, no vender has ever advertised his machine would give as many fertile eggs at the time of test as a sitting hen. If 20 per cent of all the eggs incubated are (with incubators) thrown out as infertile, is there not a big argument right here in favor of hens that has not been properly considered?

Last winter I had two or more hens that hatched every duck egg given them, and this winter I have had two hens bring off eleven ducks each, from eleven fertile eggs. There is at present (at least down here in Florida) a big complaint of eggs for the incubator being infertile; and this recalls to mind the down-east "secret" of starting all eggs under hens before placing them in the incubator. No doubt it would give excellent results if we could get enough hens to sit all at one time. This calls to mind the remark made several times recently, that the first week of incubation decides at least largely the outcome of the hatch. To test this I took thirteen eggs that a hen sat on, "off and on," for two or three days, and then "threw up the job." On testing them out I could not discover that they were in any way hastened along, or looked different from eggs that did not have this irregular heat for that length of time. In the first paragraph above I should have stated the incubator eggs showed larger and stronger germs than the eggs under the hen, indicating, probably, that I gave the eggs more heat than did "biddy." Could this explain the lack of fertility?

FIRELESS COOKERS, FIRELESS BROODERS, ETC., AND, FINALLY, THE "FIRELESS AEROPLANE."

By the way, when I spoke some time ago about a fireless *incubator*, several friends took the trouble to explain to me about a hot-water incubator, and called it *fireless*. Now, this is not only very old, but it is in no sense fireless, as you have to have a fire to heat the water, and a lamp is ever so

much simpler and less trouble. Now about the fireless aeroplane: My attention has just been called to it by the following, which I clip from the *Cleveland Plain Dealer*:

The Wright brothers announce the completion of a fireless aeroplane. Anybody can fly now—there's no danger of being drowned if one wears a cork belt, and why be hanged if you have a good lawyer? And now that one can't get burned up while flying, immortality is assured.

We don't know how much of the above is newspaper pleasantries and how much is truth; but the clipping calls to mind that I have neglected, until just now, to thank the kind friends who sent Christmas greetings to Mrs. Root and myself about the first of the New Year; and, while thanking you all, I want to tell you that I feel a lot of pride in pointing to a neat booklet on our center table that contains inside the following:

1911-1912

A MERRY CHRISTMAS AND A HAPPY NEW YEAR

WILBER WRIGHT,
ORVILLE WRIGHT,
KATHERINE WRIGHT.

When I go back to Ohio in May I am planning to go and see that "fireless" and then I can tell you more about it.

GRAPE FRUIT FOR RHEUMATISM.

I have before mentioned that grape fruit alone gave me almost immediate relief from a kidney trouble that had been afflicting me more or less for years. See the following:

A WONDERFUL FRUIT; MOST VALUABLE OF ALL.

Last month we mentioned that the grape fruit would cure rheumatism. We thought that this fact was universally known in Florida, but it seems that many of our people right where the grape fruit grows did not know that a most complete and sure cure grew right at their hands. The editor was a great sufferer from muscular rheumatism and sciatica, and it departed years ago. We do not hesitate to say that, if properly taken, and *only* if properly taken, the use of grape fruit will cure any case of rheumatism that can be found. It is nature's cure. The fruit must be eaten without sugar, or juice can be taken by a reamer, such as is used for extracting lemon juice, now made and sold generally for grape fruit, being larger. Take freely of the fruit or juice, from the fruit with a spoon, preferably every morning before taking other food. In severe cases it may be well to take before each meal. Take fresh fruit. Do not think that a half of a stale fruit is of any benefit. Many who come to spend a winter in Florida with rheumatism can go back north free from the disease. But they rarely ever want to go permanently. This recipe is not copyrighted.—*Modello Tropical Topics*.

Kind Words From Our Customers.

Dear Mr. Root:—We read the Home papers first. The notes on temperance indicate an individual who is not afraid to fight for the right. Our home city, Knoxville, is a dry town. Our Tennessee cities and towns would all be "dry" if the law were not flagrantly and openly violated.

Louisville, Tenn., Nov. 20. SARAH A. RULE.

LOOKING FOR A CHANCE TO GET "A CRACK AT THE SALOONS."

I have been a subscriber to GLEANINGS for two or three years, and I am a friend of the bee, but looking all of the time for a chance to get a "crack" at the saloon. That God may bless you in your fight against intemperance and all other evils is my wish.

Cranbury, N. J., Oct. 9. OLIVER CROSHAW.

BEEES AND RIGHTEOUSNESS.

A little over one year ago I knew nothing concerning bees. I became interested, and purchased one stand. They increased to three stands last summer. They wintered outdoors well, and now number five stands. They are a great pleasure to Mrs. Porter and myself, even if we received no profit other than the study of their lives and to work with them; but they will much more than supply us with honey.

We look forward to the coming of GLEANINGS to our home anxiously, and read it with great pleasure and profit. The Home department is especially interesting to us, and alone is well worth the cost of GLEANINGS. The stand you have taken on the liquor question, the instructions and advice, the application of God's word, must come from one led by the spirit of true patriotism and of Christ.

Byesville, O., July 12. H. C. PORTER.

"GOT THESE BEHIND ME, SATAN."

Mr. A. I. Root:—After reading your talks for Aug. 1, wherein you give your experience with the railroad agent, I feel I must tell you of a similar experience I had. When I was a boy, money was very scarce with me, so the temptation was that much stronger. I was walking along the road one day, and a little negro boy was just in front of me when I saw him drop a ten-cent piece. I picked it up and asked him if he had dropped any thing. He said no, so I put it in my pocket. As nearly as I can remember I kept it about a year. I could not stand it any longer, so I gave it back to him. A few years after that I went into a store in my home town and bought a dime's worth of something, and gave the clerk a fifty-cent piece. He gave me back 90 cents. There was the old tempter again. I took the money and walked out of the store. But the next day I carried it back to him. A few years after that I was in Richmond, Va., and wanted to go to a place on the James River. The fare was \$1.40. I gave the agent a \$2.00 note. He handed me back \$3.60. The tempter had left me then. I did not touch the notes, but took up the 60 cents and said, "That was a two-dollar bill I gave you." He appeared very much embarrassed, but said, "I am very much obliged to you." I know what it is to be a Christian, and I would not give it for all of the riches in the world. I know you are a busy man, and I don't know that you will read this; but I felt as if I must tell you about it.

R. Z. SCLATER.

"MARCHING ON."

I want to confess to taking, without your permission, from your excellent magazine a part of an article which appeared some time ago in regard to the amount of spirits consumed in the United States, and including it in an article I wrote for the *Baptist Record*, of Peella, Iowa. However, I gave you credit for what I took. Now tell me what's to pay.

One thing more. I notice in GLEANINGS, Oct. 15, you refer to John Brown as a martyr. Now, I want to say that I had two brothers with John Brown at Harper's Ferry. One was sacrificed to the Moloch slavery in Virginia, and the other afterward in Missouri. It does me good for this reason, and because he has been so misrepresented by historians, to hear John Brown spoken of as a martyr.

Again, I have read with much pleasure and profit your lay sermons, and hope to read more of them. I have been preaching the glorious old gospel myself for almost half a century; and the older I get, the more precious it seems. I am especially pleased with your warfare against the saloon. It seems to me the time has come when every lover of righteousness should speak out against this evil of all evils.

Shall tongues be mute when deeds are wrought

Which well might shame extremest hell?

Shall freemen lock the indignant thought?

Shall pity's bosom cease to swell?

Shall honor bleed? shall truth succumb?

Shall pen and press and soil be dumb?

No! by each spot of haunted ground

Where freedom weeps, her children fall,

By Plymouth Rock, by Bunker's mound,

By all above, around, below,

Be ours the indignant answer—no!

NO. 6

Editorial

MR. WESLEY FOSTER, in this issue, has a very fair article on honey-crop reports that is well worth reading.

E. R. ROOT left for Bradentown, Fla., March 4, and expects to return to his office on the 29th of the same month. This will explain why the answer to some of his letters may be delayed until his return.

THAT TOBACCO ARTICLE

In publishing the tobacco article as given on page 162 of this issue, it is not our purpose to boom or sanction an industry which we do not approve, but to show how bees pollinate the plant. In doing this we merely wish to show that if bees can pollinate what we consider to be of no real economic benefit to man they can also pollinate a plant that gives real life and health to both men and women.

EXTRA-LARGE EDITION OF OUR HORTICULTURAL NUMBER

WE are printing an extra-large edition of this special number on "Bees and Fruit," and if beekeepers will send us a list of the names of fruit men in their vicinity who might be helped by the educational articles on fruitgrowing published in this number, we shall be very glad to send them a copy without charge. In this way we hope to help the beekeepers themselves as well as the fruit men.

THE INCREASING DEMAND FOR BEES IN ORCHARDS

ELSEWHERE in this issue Prof. H. A. Surface, Economic Zoologist, Harrisburg, calls attention to the fact that there is an increasing number of orchardists who are asking to have bees located among their trees. Mr. N. E. France, General Manager of the National Beekeepers' Association, who has traveled extensively, finds that the fruitgrowers over the country are either buying bees and putting them in their orchards, or are offering the free use of their orchards to beekeepers if they will only put their bees there. In most cases beekeepers will do well to hunt up the fruitgrowers and inform them of the important work performed by bees in pollinating their trees. This should

be done at once. By so doing good locations may be secured free of cost.

SEASON PROSPECTS

IT is still too early to give any thing like a definite summary of the few reports on wintering that have come in. However, at this time it seems safe to say that the colonies in the northern States that were in good condition in the fall, and that were packed well out of doors, or wintered in good cellars, will come through without much loss. In those parts of the country where the winters are not usually severe, there seems to be quite a heavy loss, owing to the beekeepers having been taken unawares by the extreme cold. We may be mistaken; but at this date, March 11, it looks as though there might be a somewhat greater mortality, the country over, than usual.

The rain, so long delayed in California, came at last; but the general feeling is that the prospect of a honey crop is very doubtful outside of the irrigated districts, on account of the fact that sage and other honey-producing plants have made no growth owing to the very severe drouth.

In the South, the conditions in general seem to be normal, although in the southwestern part of Florida one-half to two-thirds of the colonies are dead. In the eastern and central part of the State, conditions are much better. Those in Georgia and those throughout the cotton belt, in fact, are in fine order; but those in other parts of the South, not near the cotton belt, are in rather poor condition, owing to the drouth during the latter part of the summer. In the clover regions of Mississippi and Alabama the bees are in good condition. Reports from the Carolinas indicate that there has been no more loss than usual.

Most of the few reports that we have from Illinois indicate rather heavy losses, although when the full returns are in, a summary of the whole state may not reveal serious losses. Scattering reports from other parts of the country do not show any thing very definite as yet. This winter has emphasized most plainly the importance of having the colonies headed by young, vigorous queens that will make certain a good proportion of young bees in the fall.

ORANGES AND BEES

THE cover design of this issue shows a beautiful orange tree in what is known as the Sespe apiary, belonging to Mr. J. F. McIntyre, of Ventura, Cal. The hives of bees are shown under the trees in the background, while the orange tree in the foreground is loaded with fruit. We regret that we are not able to show the beautiful color values of the oranges and the dark glossy leaves in contrast.

It might be interesting to recall that this apiary has, or did have, at least, something like 500 colonies in it. There seem to be only two yards in the United States that have as large a number of bees in one spot as this. The other apiary to which we refer is the Alexander yard, located at Delanson, N. Y.

The bees at the Sespe apiary work on the orange bloom in the immediate vicinity, and on the mountain sage when it yields. In this particular case, bees and fruit, or, if you please, bees and oranges, go well together.

HARD CANDY FOR WINTER AND SPRING
FEEDING; HOW TO MAKE IT

INTO a dish of hot water on the stove slowly pour an equal amount of sugar, stirring constantly. Make sure that the sugar is all dissolved before boiling commences. If this precaution is not observed, some of the undissolved sugar is likely to burn, injuring the flavor of the candy and almost surely causing trouble with the bees later. If you have a candy thermometer, watch the temperature, and do not let it go above 275 to 280 degrees. Test frequently by dropping a very little of the syrup into cold water (about 50 to 55 degrees F.). When the boiling has continued long enough the drop of candy, when cooled in the water, should be hard and brittle when taken out; but when placed in the mouth it should soften slightly, so that it is tough. When this time has arrived, pour the syrup immediately on to paraffined or waxed paper on a table. Have the table perfectly level, and around the outside of the paper put wooden sticks $\frac{1}{4}$ -inch high to confine the syrup and prevent it from running off. When the candy is nearly hard, cease it or cut it with a heavy knife so that it may be broken up into right-sized squares when hard.

The color of the candy when cold should be about that of light basswood honey. If it is darkened very much it is scorched and unfit for the bees. To prevent the scorching, reduce the fire toward the last so that the syrup will boil but slowly.

When the candy is first made, it is hard and glassy, and perfectly transparent; but after it stands for a little time it becomes somewhat watery and crystalline; but this is all the better so far as the bees are concerned, for they are enabled to take it more easily.

The thin cakes of candy being only $\frac{1}{4}$ inch thick may be placed over the frames

and under the regular cover, and in this way a colony saved that would otherwise be lost. The feeding of syrup, especially in the spring, is apt to cause great excitement and possibly robbing, and for this reason the candy is safer because it takes it slowly.

BEES WORTH A HUNDRED MILLION DOLLARS
AS POLLINATORS

HAVING occasion recently to deliver a talk on the relation of bees to horticulture, at the Ontario Agricultural College, Guelph, Canada, we made the statement that bees produce annually \$20,000,000 worth of honey; but that their economic importance to the fruitgrower and the consumers of fruit in this country could be measured by five times that in the production of more and better fruit and better crops. After we had concluded our talk we asked the botanist who heard this talk if this statement, in his opinion, was too strong. He very promptly replied that it was not.

Neither the beekeeper nor the fruitgrower fully realizes the important work the bees perform in pollinating fruit-blossoms throughout the country, especially the finer fruits such as plums, cherries, peaches, pears, and most apples. There are very few fruit trees that are self-pollinating. Charles Darwin made the statement that nature abhors self-pollination. As bees, in most cases, are about the only insects that are in the air at the time most of our trees are in bloom, it follows that they are the main sources of cross-pollination. Fortunately, our best horticulturists and fruitgrowers are to-day the bees' best friends. It is only the narrow-minded and the uninformed who complain of the bees being a nuisance in orchards and vineyards. The overripe and otherwise imperfect fruit from damage or otherwise should be picked off early and marketed locally rather than to hang on the trees, or, worse yet, lie on the ground in a half-rotted condition, attracting the bees.

The only time that bees are said to be a real nuisance is when cut fruit is placed out to dry in California and elsewhere. It may be questioned whether it is best to put out fruit to dry in some places subject to disease-laden germs of all sorts. It would seem that legislation should properly safeguard the outdoor drying; for why should we eat dried apricots and prunes that are coated with dust? We have been in *some* (not all) fruit-drying ranches in California where the dust was flying in all directions. If some of our Eastern consumers could see the way this fruit is exposed they would say better by far that the bees should eat it *all*, rather than have it placed on our tables laden with disease-bearing germs.

BEES AND GRAPES

COMPLAINTS seem to be increasing of how bees "eat grapes." In every case that has come under our observation we do not know of *one* where the bees were the real and pri-

mary cause of the damage to the fruit. We would call attention to the excellent reply to a correspondent by Prof. H. A. Surface, Economic Zoologist, Harrisburg, Pa., on this subject, in this issue. See page 158. Prof. Surface is one of the best authorities in the country on the relation of bees to horticulture. He has conducted some thorough experiments, and furthermore is an entomologist, zoologist, fruitgrower, and beekeeper. What he has to say in this issue should be given some weight.

We find that the Cape May warbler (*Dendroica tigrina*) is the real culprit, and not the bees, in this locality at least; and we have reason to believe that in many others the small holes made in the grapes attributed to the bees are made by these birds that come on early in the morning. They run their beaks into every berry in a bunch. Instead of using up one berry they make a single hole in every berry, thus ruining the whole bunch. Indeed, they will go over a whole vineyard in that way. As one is not usually up at that time of day, the birds are not discovered. The bees come along about eight o'clock, and, of course, run their tongues down into the holes made by the birds. The bees are caught in the act; and after they leave, these small holes are discovered. The natural conclusion is that the bees are responsible for the whole trouble. Beekeepers should take pains to inform their grape-growing neighbors about these birds.

PUBLIC SENTIMENT GROWING AGAINST THE SPRAYING OF FRUIT BLOSSOMS.

In any locality where there are fruit-growers so behind the times, and so ignorant as to insist on spraying their trees while in bloom, it is a good plan to create a public sentiment against the practice. The leading experiment stations and horticulturists in the country are now very explicit in their condemnation of blossom-spraying, so there is no lack of evidence, even from a fruit-grower's standpoint, showing that it is a bad plan. One way of creating such a sentiment is to get the editor of the local paper to accept an article that is at once interesting and readable, and yet full of proof that fruit blossoms should not be sprayed.

One of our subscribers, E. L. Dresser, of Ithaca, N. Y., who has had considerable trouble along this line, was at last stung into action, and he sent to the *Ithaca Daily Journal* a statement in which he spoke his mind on the subject. We have not room for the whole article, but we give herewith parts of it to show what can be done:

To the Editor of *The Journal*:—A short time ago our sensibilities were shocked by the accounts of a mother who poisoned her child by compelling it to drink carbolic acid. So outraged was the public, that, when the woman was taken to Albany for trial, mob violence was feared, and a special force was called out to guard the prisoner from the station to the jail.

Yet within our own "Biggest Little City" last summer thousands of little lives were destroyed by poison, no account of which reached the papers, nor was it of any seeming consequence save to a few interested parties.

The honey-bee is the friend of humanity. Not only do these little gatherers produce annually thousands of tons of the most delicious and healthful sweet known to man, but in their quest they pollinate the flowers, and thus multiply by many bushels and barrels the fruits and vegetables to the enrichment of the producer and the benefit of the consumer. Thus the honey-bee is a friend not only to the orchardist and fruitgrower, and every one who has a fruit tree in his yard or a vine in his garden, but to the whole human race.

After many careful experiments at both the State Experiment Station and the Cornell Agricultural College, the conclusion was reached that, to spray the fruit trees when in bloom, is a positive damage (see Experiment Station Record, Vol. 13, p. 364).

As a result, the Legislature passed the following law:

"Any person who shall spray with or apply in any way poison or any poisonous substance to fruit trees while the same are in blossom is guilty of a misdemeanor punishable by a fine of not less than ten nor more than fifty dollars, etc." (see Chap. 171 of laws of 1900).

C. E. Layman, of Troutville, Va., in an article in *GLEANINGS IN BEE CULTURE*, March 1, 1911, says: "I have had a great deal of experience in the spraying of fruit, and have watched some of my neighbors frequently who persisted in spraying while trees were in bloom, and in nearly every instance their fruit was damaged more or less, while my trees, which had not been sprayed until after the bloom dropped, were full of perfect fruit. There can not be any doubt about this point in my mind, as has been so thoroughly demonstrated in this section."

An extensive orchardist of Washington writes in the *Pacific Homestead* of last October: "I am satisfied that most orchard men do not realize the importance of proper cross-pollination of their fruit. Inasmuch as the bee is practically the only insect flying at the time apple trees are in blossom, their chief reliance must be placed upon it. While wind does carry pollen to a certain extent, many experiments have shown that it is only to a slight degree. It will pay the fruitgrower to keep bees to pollinize his fruit, or at least he should be willing to encourage some of his loving neighbors to keep them."

Mr. Terry, president of the Vermont Horticultural Society, in a recent public address said that in Grand Isle Co., where are located some of the best orchards in the State, he and another party examined every orchard with great care to discover if possible the cause of failure in some to produce as heavily as the others.

The results of examination showed in every instance that, where there were failures to produce abundantly, there were no bees, or too few to be of much use; and further, that, where a good supply of bees was kept, there was in every instance a large apple crop.

Ithaca, May 1, 1911.

E. L. DRESSER.

Another way to create public sentiment is to have some good speakers at farmers' institutes, horticultural-society meetings, etc., to present the matter and show the good work that the bees do, as well as to make it clear that, even from a fruitgrower's standpoint, blossom-spraying is not advisable. The following clipping from *Successful Farming* illustrates just what we mean:

THE AID OF BEES IN ORCHARD WORK.

At a recent meeting of the Vermont Horticultural Society much emphasis was placed upon the keeping of bees. Last season was wet and cold in spring, and not conducive to a good fruit crop; and those who have set and cared for large orchards of their own have observed that the orchards or parts of orchards near stands of bees bore well while those at a distance did not. The apple blossom is so constructed as to render the work of bees necessary to pollination.

This is the reason why trees bear so much better and more evenly in warm dry seasons.

One speaker said that he had about 30 hives in and about his orchard, and it bore heavily last year, which was not a good fruit year in Vermont.

—*Successful Farming*.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

REV. L. P. HOLMES writes that he also had a live drone from a queen-cell. It was in 1908, the cell was extra large and fine, he caged it, and after the usual 24 days a drone of ordinary size emerged. Last year he had a queen-cell caged, and several days after it should have hatched he opened the cell, finding a fully developed queen, dead, with its head toward the bottom of the cell.

THE BUMBLE-BEE seems in danger of being thrown out of its job as a pollinator of red clover. The *Country Gentleman* reports an invention said to do the work better than the bumble-bee. It consists of a huge brush with about 200 vulcanized-rubber tips to the square inch, which is driven over the clover-field, carrying the pollen from one blossom and depositing it upon another.

TO GET HONEY out of cappings, put them to drain in a container with holes in the bottom; when they will no longer drain, put them in a damp cellar, where they will attract moisture, and the thin honey will drain out to be used for vinegar or bee-feed. Or, instead of taking them into the cellar, put them outdoors in a long box with one end raised, and turn the box end for end as often as the bees dig the cappings down level.

LARVÆ. Nearly had a fit the other day on learning that this word should be pronounced *lar-vee* when all my life I've been saying *lar-vay*. I refrain from adding that it may be also called *lar-way*, lest it throw most of the readers of GLEANINGS into fits. [The pronunciation here will depend on whether one uses the Roman (or continental) pronunciation for Latin words, or English. When we were taking Latin at school we had the English pronunciation, and the final syllable of *larvæ* would have the long sound of *e*. Later on in college, we had the Roman pronunciation; then the same final syllable would have the long sound of *a*. Either way is right.—Ed.]

SAMUEL SIMMINS thinks beekeeping in this country has retrograded on account of the use of so shallow a frame as the Langstroth. He says, *Canadian Bee Journal*, 10, "Editor E. R. Root states that the average yields, taking the United States all over, would probably be 35 lbs. of comb honey, or 75 lbs. of extracted. Has bee culture so degenerated that even to-day the results from the old let-'em-alone style of beekeeping can not be exceeded?" But where is the degeneration shown, friend Simmins? You don't for a minute think that the old let-'em-alone style yielded 35 lbs. of comb per colony, do you? Although there are still enough let-'em-alones mixed with the up-to-dates to bring the average down to 35, that average is probably better than it ever was before. [If our friend Samuel Simmins

were more familiar with conditions as they are in the United States he would not make such statements. For instance, he says our Langstroth frame is responsible for two-thirds of our winter losses. When expert beekeepers all over the United States and Canada using Langstroth frames do not lose during winter to exceed five per cent of their bees, and usually not over two per cent, the Langstroth frame, we may conclude, is doing pretty well. It could hardly do better. Some of the former advocates of deep frames for winter are now using Langstroth frames. See reply to F. P. Clare, p. 179.—Ed.]

D. M. MACDONALD, *British B. J.*, p. 514, concludes that I give hybrids a bad reputation because I practically say that nine-tenths of the weaklings are hybrids. My good friend, however bad hybrids may be, that statement doesn't charge them with badness. Nine-tenths of the weaklings are hybrids, and so are nine-tenths of the *stranglings*, because nine-tenths of all the bees are hybrids. See? Allee samee, the average hybrid is inferior to the Italian—in my opinion. You ask why, for 50 years, I clung to such bad bees. I didn't—not to *average* hybrids. I bred up a strain of hybrids that were better than Italians. More fool I. If I had stuck to pure Italians I might have had still better bees.

G. M. DOOLITTLE thinks no need to have bees closer than two or three miles from pasture. Out west, if I remember, the authorities advise that in orchard regions bees should be not more than a mile apart, so they need travel only half a mile or so. Likely both are right. In hot weather bees can go two miles just as well as half a mile to gather honey; while in the cool and catchy weather during fruit bloom half a mile may be enough. Yes, I once thought two miles apart was well enough for orchards. But I'm older now. [This is a question of locality. Where bees can fly from a hill over a wide valley, so as not to encounter woods, they go much further than over perfectly level country. We have traveled over a very large portion of the United States where bees are kept, and wherever we have gone we have asked the question, "How far do bees fly?" For level country the general response is, "Not more than a mile and a half; usually not over a mile." While their bees will, of course, fly further, the claim is made that they do not work to advantage. In hilly country, such as we find in New York, bees will sometimes fly five miles to gather buckwheat honey. This has been demonstrated very conclusively at the Alexander apiary, at Delanson, N. Y., and in other places in that State where we have traveled; but we think that in most places in New York bees will not go much over a mile and a half to advantage.—Ed.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

It is interesting to read Doolittle's views of the long and short haul of honey by the bees. It is certainly comforting to think that our bees can reach flowers five miles away; but I have a suspicion that not a little depends on the bees. Now and then we find a colony gathering when others are not showing they can go further or search closer.

I was interested in Mr. Mollett's description of wintering bees in the South. Fifty to seventy-five pounds per hive! Why, it almost takes away one's breath to think of a colony consuming that much. But then I congratulate myself that, if our bees of the North are not at work during our long winters, they are not consuming honey beyond all reason.

We are under obligations to the editor of GLEANINGS for the careful experiments which were made for the purpose of determining the amount of wax used by bees in drawing out a sheet of foundation into a full comb, page 711, Dec. 1, 1911. According to these figures, furnishing an eight-frame hive with full sheets of foundation would save the bees the necessity of making one pound of wax that would doubtless take twelve pounds of honey to produce. This, at ten cents, would be worth \$1.20, or twice what the foundation costs; and yet some beekeepers think they can not afford it.

As to the question whether buckwheat yields honey only during the night or at certain times of the day, or all the time, I believe that it does about as it has a mind to, acting quite differently sometimes from other times. Where I lived in 1867 there was an unusual amount of buckwheat sown that spring, and not a large number of bees kept; and I noticed that, at the beginning of the season, the buckwheat yielded nearly all of its honey in the forenoon; but later in the season the flow of nectar was later in the day, until at its close the flow was almost entirely confined to the afternoon. Now, I doubt not that there are some places where it yields all day, and I am quite sure there are some places and seasons where it doesn't yield enough to be worth mentioning.

Dr. Miller refers to me, page 36, as saying that moths do lay eggs in sections after taking them from hives. Let me say here, to prevent misunderstanding, that our experience has been that moths do not lay eggs in our sections after they are taken from the hives, because the sections are stored where the moths can not get to them; but I always find more or less *larvæ* of the wax moth developing on combs of section honey after they are taken from the hive. If the combs are white and clean, little harm is done; but if any cells of pollen are found,

or the combs badly soiled or "travel-stained," these "varmints" will develop and do lots of harm unless treated to the fumes of sulphur.

The same seems to be true of extracting-combs until they have been frozen so as to kill all eggs or larvæ of the waxmoth. Where do the eggs of the wax moth come from if no eggs are laid by the moths after the combs are taken from the hives? Moses Quinby gave it as his opinion, after very careful experiments, that the moths lay the eggs at the entrances of the hives, and the bees carry them in on their legs or bodies, and scatter them over the combs. Those hatching inside the hives are, as a rule, in every strong colony, quickly taken care of by the bees; but when the combs are removed they develop. If I remember rightly, Mr. Quinby took off boxes of honey, and watched to see that no moth entered; and when every bee had gone out of the box it was sealed so no moth could enter; but if kept in a warm place the larvæ of the wax moth would develop just the same as when exposed to moths.

The recent articles by John N. Lovell, on flowers, are of more than usual value. Somewhere I have seen the statement that Christ, whose life and teachings have attracted so much of the world's thought during the past eighteen centuries, was the first to call the attention of mankind to the beauty of flowers. I can not vouch for the truthfulness of the statement; but one thing is certain—he was a great lover of flowers. Indeed, I think we may say that he was a child of nature, with the hills and valleys, the fields and flowers his teachers. "Consider the lilies, how they grow," is as much a command of Jesus as any other, and if it is our duty to consider the lilies, we may infer that it is also our duty to consider the sweet peas and morning-glories, the apple blossoms and wild asters, and a thousand other objects of beauty on every side of us, too numerous to mention. I have read in an old book of the servant of a prophet who, one morning, was frightened almost out of his wits because he saw a few soldiers encamped on the outskirts of the town, and his master prayed that his eyes might be opened, and they were opened, and he saw more wonderful sights than he had ever dreamed of; and so when our eyes are opened to the beauties and wonders of all about us we shall find more to enjoy and entertain us in our leisure hours than we could ever have believed in our wildest dreams. It is thought a good sign that people are going back from the city to the land, and I am sure it is a good thing when those with literary ability write of nature and all its wonders rather than myths and impossible creatures. There is enough of the real and true to satisfy any sound mind.

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas

BEE CULTURE AND AGRICULTURE; SHOWING THE MUTUAL INTERESTS OF BEEKEEPER, FRUITGROWER, AND FARMER

Outside of the beekeeping world it is not generally known nor even understood that honeybees were created, not so much for the purpose of furnishing the delicious honey for mankind, as for carrying pollen grains from one flower to another, so that these may bear fruit and seeds. The pollen is gathered by the bees from the flowers, and carried to the hives in little bright-colored pellets on their hind legs, which many persons suppose is the wax from which the combs are built. The bees, however, must gather this yellow dust or pollen from the flowers, to prepare the partly digested food for their young larvæ. This is absolutely necessary; and if they are unable to secure a sufficient amount of pollen the progress of the colony is delayed considerably. In gathering either pollen or honey the bees come in contact with the pollen grains of the blossoms, which adhere to their hairy bodies, and are thus carried from one flower to another. These pollen grains thus come in touch with the stigma, or the female part, so to speak, of the next blossoms visited. Cross-pollination is thereby assured, and the thorough setting of fruits and seeds the result.

Bees are most important distributors of pollen, because they appear in larger numbers than other insects, and especially in the early part of the season. It is this reason, as well as their greater activity, that makes them more useful in this great work they help to perform, the value of which, as estimated by good authorities, is far greater to our country than the value of the honey crops. It is certain that the bees, on account of their greater numbers, visit a far greater number of blossoms, and do this work more thoroughly than other insects.

THE SEX IN PLANT LIFE

Sex in plants or flowers exists very much as in animals, and it is just as necessary that fertilization take place before fruit or seeds develop. In many plants the male and female exist in the same flower. In others the male is found in one and the female in another flower of the same plant, while in still others each sex is found in the flowers on separate plants entirely. No matter what the arrangement, however, it is necessary that the pollen grains from the anthers of the male part of one blossom reach the stigma of the female part of another. The pollen grains of one blossom ripen earlier or later than the stigmas, so that self-fertilization is prevented, and the bees carrying the pollen to the other blossoms in the right stage to receive it effect and complete the fertilization, after which the de-

velopment of fruit and seed follows. Without this pollination the blossoms would wither and die instead of bearing fruit.

SOME STRIKING EXAMPLES

During the most favorable weather conditions the pollen grains may be blown about by the wind, and pollination of the blossoms take place so that fruit may be borne. But even under such conditions the bees play a great part in making the work more thorough, as they visit many flowers and blossoms that may not be reached by pollen driven by the wind. It is well known that such ideal weather conditions do not always exist; and during such conditions, when the weather is damp and the pollen sticky, the wind does not blow it about so easily, and it is then that the insects, and especially the bees in their large numbers, play the most important part in the crop of fruit and seeds that will be harvested. Where certain varieties of plants or fruit trees are isolated from others of their kind, and when there is a great distance between them, the chances of pollination are not certain, and the bees must be depended upon to carry the pollen from one to another. Where bees are not present, and the wind only depended upon, there are instances on record of trees that bore no fruit on the windward side, but an abundance on the other side. The presence of bees would have insured the pollination of the blossoms on the windward side, and a better setting of fruit on all parts of the tree.

DO BEES PUNCTURE FRUIT?

It has often been stated that our bees puncture fruit; but numerous experiments show that this conclusion is ungrounded, their mouth parts being so constructed that they can not break the skin of any kind of fruit. They appear only after birds or insects have caused the skin to break, and then only to gather the sweet juices from the bruised fruit. Many experiments in which sound fruits were hung in hives of bees have proved absolutely that the bees can not puncture the skin of sound fruit, even if they are starving for want of food.

POISON-SPRAYS AND BEES

As the insect depredations are becoming more and more harmful to various crops, man must protect himself against these insect pests or bear considerable loss. For this reason spraying is being practiced more generally. The thinking person will not kill his best friends, the bees, by spraying during bloom, for the greatest authorities have shown that it is not only unnecessary but dangerous. In many States there are stringent laws against spraying during fruit bloom.

BEEKEEPING IN CALIFORNIA

P. C. CHADWICK, Redlands, Cal.

The problem confronting us in Southern California is not how to keep more bees, but how to keep what we have until a season of more bountiful rainfall.

The report of the Northern California Beekeepers' Association, by W. A. H. Gilstrap, has the true ring and the "get together" spirit, which I hope will do much toward the building of a great harmonious State association that will enable us to do something besides "resolve."

In behalf of our retiring President, Mr. B. G. Burdick, I am going to extend a vote of thanks for the State association, this matter having been overlooked in the rush at the close of the session. Mr. Burdick wielded the gavel, so far as I know, to the satisfaction of all.

The gentleman who accompanied the State demonstration train (I did not learn his name) said before the State association that European foul brood (black brood) could be cured with any kind of bees provided the colonies were strong enough. In this I believe he is badly mistaken. No doubt strength is a great factor, but in itself it is not sufficient.

Northern and Central California will probably produce much more honey this year than the southern part of the State. Indeed, it is quite possible that, before many years, there will be a thinning of ranks in our Southland for more desirable locations over the ridge. The seasons here are much like the little girl who had a little curl in the middle of her forehead—"when they are good they are very, very good; and when they are bad they are *horrid*."

February has passed without a drop of rain; the usual pollen-bearing spring flowers did not germinate nor dry up when small, for the earth is as dry now as it was last midsummer. Spring breeding in many places is almost at a standstill, and the outlook even for orange honey is the most gloomy of any time for nearly ten years. Optimists say we shall have rain yet; but we have had this false hope so long that my mind is very much akin to that of the man from Missouri, who had to be shown.

HOW EDUCATION AFFECTS THE DEMAND FOR HONEY.

The people of Texas have been fed on bulk comb honey until they now demand it. Colorado seems to have fed on section honey, while out here we have taught them to eat extracted, and the quantity consumed is wonderful. One grocery in this city sells an amount running into tons each year. Beekeepers sell many five-gallon cans to

families, nearly all of whom return their cans to be refilled the following season. One enterprising young man put some bulk comb on the local market two years ago, giving his entire supply to one grocer to dispose of, and a demand was created that was hard to fill. The young man has since left the city; but the demand for his ware remains at that store. A majority of people call extracted honey "strained honey," and believe it is squeezed out through a cloth. If this one false idea could be overcome it would add much to the demand for this product. People follow their education pretty closely, whether it be social, religious, or on other lines. Many, no doubt, remember the time when grandma or grandpa "robbed" the old "gum," carried in a quantity of honey, "bee bread" (and likely some brood), and really strained it. Is it any wonder the idea is hard to overcome?

DRASTIC COUNTY ORDINANCES.

Ventura County has passed an ordinance that "all bees not bearing an inspector's certificate will be destroyed on arrival," while Imperial County Board says no more bees shall be brought into that county. It is rather laughable to read how some of our county boards are going to block the avenues of trade or kill it when it arrives. Personally, I think these county boards are well-meaning gentlemen, but poorly advised. Not a great while ago some one persuaded the city trustees (of Redlands) to pass an ordinance prohibiting any person from keeping more than five colonies of bees in the city limits. The ordinance was attacked in the superior court, and defeated. There is little doubt, in my mind, that such county ordinances as mentioned above would meet the same fate if taken into courts, for these reasons: One county can not legislate against another. Such regulation comes under State jurisdiction, while no court would allow the destruction of healthy bees any sooner than it would domestic animals. If every county in the State should pass an ordinance identical with that of Imperial County, there would soon be a condition that would be intolerable. Migratory beekeeping is a part of our modern-day progress—has come to stay, and can not be stopped by a few county boards. Such drastic ordinances, in my opinion, will hasten the day when we shall have a State law that will be effective without trying to prevent free movement, or the destruction of healthy bees, for the very good reason that these same counties want protection, and will back a good State law solidly when they meet defeat in what they have. I am not opposing quarantine laws by any means; they are becoming indispensable; but I am opposing those things that are neither good law nor common sense.

Conversations with Doolittle

At Borodino, New York

OVERSTOCKING A LOCALITY.

"I have fifty colonies of bees and desire to increase to as many as my locality will support. Then, if I see my way clear, I may start some out-apiaries. Now, what I want to know is, about how many colonies I can profitably keep in one place. I have asked several beekeepers about this, and I find a great diversity of opinion. Some tell me that fifty is enough, as it takes more than two-thirds of the nectar in most fields to sustain the colonies during the year. Others say that Mr. Alexander kept 700 colonies in one apiary and got splendid returns from them. What is your opinion?"

"Overstocking a locality is a subject which has puzzled many a beekeeper; and deciding upon the number of colonies of bees that may be kept profitably in one locality is difficult, even for one who has given much thought to this subject. If I am right, Dr. Miller has said somewhere that there is a limit beyond which one can not profitably increase the number of colonies in an apiary; but just where that limit is, can, perhaps, never be learned. He said that, if he were obliged to make a guess, he would think about eighty colonies in one apiary would be the limit of his location. You will note that he was talking about *his* locality, which may be better than the one you are in, or it may not be as good. Therefore a knowledge of the locality one is in is one of the important factors which must be taken into consideration.

Then, again, the seasons are so unlike in different localities that it will never be possible to do much more than to estimate approximately the number of colonies that may be profitably kept in a certain location. It will also become apparent to all that a different approximation must be made for each locality.

"Mr. Alexander was in a most propitious locality—one in which there were thousands of acres of buckwheat sown every year. This, in addition to clover and basswood, gave something which every beekeeper would thoroughly enjoy. But Mr. Alexander did not decide that 700 colonies was about the right number for him to keep, without years of experience in and with his field. Therefore *experience* comes in as a very important factor, and that experience must cover several years in any given locality before any thing like a correct estimate of how many colonies can be profitably kept can be made.

"Still another factor which must be taken into consideration is the stability of the field. When I first began keeping bees, there were great forests in sight of the apiary in every direction, and many of the trees were basswood, some of them four to five feet across at the stump, and eighty feet tall, with great spreading branches. Basswood lumber of the best quality could be

purchased then for \$8.00 a thousand feet, and at that price there was little incentive to cut these trees, save those dying of old age. But in the years since then, the price of such lumber has gone to \$12, \$20, \$25, \$30, and now to \$35. The result has been the denuding of these forests until very few basswoods remain except in gullies and other out-of-the-way places where it is almost impossible to get logs. In former years there was no failure in nectar from this source, so that, in three seasons out of four, during the blossoming of our basswood, 400 colonies set down here could not begin to collect the nectar. But now this is all changed, and a good crop of basswood honey from one-fourth that number is the exception rather than the rule. In fact, if mustard, white and alsike clover, and buckwheat had not materially increased in this locality during the past fifteen years, beekeeping would be no longer profitable, where for twenty years in succession my average yield of section honey was 85 pounds per colony. With the prices at from 22 to 28 cents a pound for section honey, apiculture was very profitable in those days when basswood forests surrounded many of the apiaries in this State.

"In deciding this question of overstocking the home apiary to an extent sufficient for dividing the number and taking part of the colonies to a different locality, allow me to suggest that it costs more to manage bees away from home than it does in a beeyard near your back door. The average yield of the home apiary might be cut down considerably from the increase of numbers before it would be profitable to start an out-apiary in some locality from five to ten miles distant. An out-apiary requires the purchase of a team, automobile, or some means of conveyance for use in going to and fro, as well as a change of methods, non-swarming and other systems, all of which bring added expense. But after once starting in the out-apiary business, the establishing of one or more additional apiaries is not such an expensive affair as was that of the first one, for all of the things necessary for the first can be used in any of the apiaries subsequently started."

How Bumblebees Puncture the Nectaries of Bean-blossoms

When my broad beans began to bloom I noticed that the bumblebees were always around; yet in the majority of cases the blossoms failed to set. I then noticed a hole at the base of the flower like that made with a pin, and this hole was not found in the newly opened buds. One day while wondering about this I saw one of the bumblebees, of which there are several kinds, go to a flower and deliberately eat a hole and then extract the honey as if it had been at the job for years. So it missed the pollen.

General Correspondence

BEES IN RELATION TO HORTICULTURE

BY H. HARLEY SELWYN

That the honeybee (*Aphis mellifica*) forms an important link in successful agriculture is now very generally recognized. The large annual production of honey and wax due to the industry of these insects is of very considerable economic importance; but in addition they probably play almost as important a part in materially increasing the yield and quality of the various fruits in the orchards and gardens scattered throughout the land.

That bees are intended by nature to aid in the pollination of flowers, there is no doubt, as the pollen and nectar secreted by the flowers are both absolutely essential to the life of bees, and consequently they are eagerly sought for by them. It is true that other insects, as well as atmospheric conditions, aid in this work of pollination to a considerable extent; but these other insects are comparatively few in number during the earlier part of the season, and, besides, they appear to visit the flowers only for the nectar which they contain, whereas the bees are in search of both pollen and nectar; and at the time when the orchards are in bloom the requirements of the hive, on account of the many thousands of young larvæ therein, require large quantities of pollen. For this reason, if climatic conditions should be unfavorable for the secretion of nectar, the bees would, nevertheless, visit the blossoms in order to gather the pollen which is so necessary, and in so doing accomplish the end in view, namely, that of transferring particles of pollen from one flower to another, or from the stamens to the pistils of individual flowers, and thus bring about their proper fertilization.

IF THE BEES ARE KEPT AWAY NO FRUIT WILL SET

Numerous experiments have proved conclusively that comparatively little fruit will set if fertilization depends solely upon the carrying of the pollen by the wind and other minor agencies. In proof of this it has been recorded that two trees of the same kind, both heavily laden with bloom, were selected, the one being protected with cheesecloth and the other left uncovered, with the result that the former set practically no fruit, while the one left accessible to the bees, of which there were large numbers in the vicinity, owing to the proximity of an apiary, bore an abundant crop. This is but one of the many striking examples which might be cited to show the importance of bees in relation to horticulture.

There are, it is true, seasons when fruit trees of all kinds are so heavily laden with bloom, and the weather conditions are so ideal for pollination, that, even with the ordinary agencies, sufficient fruit is set to in-

sure good crops. Unfortunately there is also the reverse side of the question when the period of fruit bloom is accompanied by dull, cloudy, and possibly wet weather, with but scant periods of sunshine. At such a time the farmer or fruitgrower who is fortunate enough to have a large apiary in or near his orchard will surely benefit greatly, as, even if there are only a few hours of sunshine each day, tens of thousands of bees will visit the blossoms during that period and effect the necessary fertilization which otherwise, owing to unfavorable conditions, might and probably would not have taken place. It would be very difficult to say just how many colonies are required to the average acre, whether it be trees or flowers that the bees are forced to visit; but it is safe to say that most localities are never overstocked with these very necessary insects. In fact, it is generally the reverse; and as a result there are undoubtedly many tons of honey going to waste annually for the lack of gathering, not to mention the hosts of plants that never succeed in accomplishing that most necessary function, namely, the proper development of the seed ovary, and consequently do not reproduce their species to nearly the extent that nature intended.

SPRAYING DURING FRUIT-BLOOM INJURIOUS

So much has been said and written on the subject of spraying and its important relation or effect on bees that it is hard to deal with the subject in other than a general way in an article of this nature; but perhaps a general resumé of the main points would be of interest.

The question of poisonous solutions used in spraying to combat the many injurious insects and fungi peculiar to fruit trees and bushes of all kinds, and the proper time for their application in one which is worthy of careful attention, especially in view of the fact that spraying is now being advocated as the one and only means of insuring the production of perfect fruit. It might be expected that the individual who owns an orchard, even though it be a small one, and who has become sufficiently familiar with up-to-date methods to practice spraying, would realize the injurious effects such spraying will have on any bees in the neighborhood if this work is done during the period of fruit bloom, and, consequently, would refrain from making the applications at so critical a period; but, unfortunately to relate, there are still far too many occurrences of this nature as the seasons come around, notwithstanding the efforts of the numerous beekeepers' associations to enlighten these misinformed individuals.

BEEKEEPING AT EXPERIMENT STATIONS

That the importance of beekeeping is becoming more and more generally recognized in the United States and Canada is evi-

denced by the fact that specialists are being employed and apiaries established in connection with the various agricultural colleges and experiment stations of both countries. It is to be hoped that, by this means, in addition to the mass of useful information on the subject contained in the leading apicultural journals of the present day, this important branch of agriculture will make rapid strides in the future. Notwithstanding the educational opportunities on the subject and the improved methods now available, there will probably always be a large number of beekeepers who will continue to keep their bees in a haphazard way—that is, in the old box hive or any other receptacle handy. It is, however, an ill wind that blows nobody good, as the saying goes, for the rapid spread of American and especially European foul brood may perhaps, in the end, prove to be a blessing in disguise, inasmuch as it is almost sure to put out of business thousands of these so-called “beekeepers” who in reality do more harm than good in the neighborhood, as their bees are too few in number to be of very material assistance, but at the same time capable of transmitting the honey containing the germs of these malignant diseases.

Ottawa, Ont., Can.

BEEES CAN NOT INJURE SOUND FRUIT

How to Prevent Grapes from Being Punctured by other Insects and Birds

BY PROF. H. A. SURFACE

[A copy of the following letter by Prof. Surface, in answer to a correspondent, was sent to GLEANINGS. We regard it as a most convincing statement; and coming from such a recognized authority we are glad to place it before our readers, withholding the name of the original inquirer.—ED.]

Replying to your letter asking if there is any practical means of preventing bees from destroying grapes, I beg to say that the bees themselves do not attack the grapes excepting when the grapes themselves are overripe or have been punctured by other kinds of insects, such as wasps and yellow-jackets, or by birds, when they have been diseased by disease germs, which would eat their way through the skin of the grape. It is impossible for bees to make holes in grapes that have not been previously damaged in some way. I have tried this again and again. After the holes are once made the bees suck the grapes dry. This really is a benefit to the grapegrower, because it prevents his packing in his shipping packages a lot of grapes that were damaged, and, therefore, would be sure to sour and start decay in the cluster, and spoil the package.

However, what you need is information as to the method of preventing the grapes from being injured by the original depredators. The most effective means of doing this on a limited scale is by bagging in paper bags. You can buy two-pound paper bags by the thousand or ten thousand at a low price. A woman can place hundreds of

them around the clusters in a day. Fasten them with a pin at the base of the entire cluster of grapes. This should be done just after the blossoms fall, or before the grape berry becomes the full size of a buckshot. This will not only prevent damage as they become ripe, but will prevent injury by the curculio, the grapeberry moth, disease germs, etc., and will give you fruit that will justify it.

If you were an experienced grapegrower you would not need to be asking for information as to how to prevent injury from them, because, in the great grape belts, this is handled by spraying; and there, where the production is by many tons per year, the proper thing to do is to spray the fruit and vines several times during the season with the Bordeaux mixture and arsenate of lead. Use the regular formula of Bordeaux mixture, of three pounds of bluestone and four pounds of lime in fifty gallons of water, and add to this two or three pounds of arsenate of lead. Make the first spraying just after the buds burst in the spring, the next spraying after the blossoms drop, and about the time the bags would be put on if you were going to bag instead of spray. The next spraying should be about three weeks after this, and again should be repeated in three or four weeks for two or three intervals.

If you are not a commercial grape-grower, the bagging will be found cheaper and more satisfactory than the spraying, because a man who does not understand thoroughly extensive spraying, will not, as a rule, do it properly. If you are an extensive grape-grower, but do not live in a region of large commercial growing of this fruit, I would by all means advise you to go during the proper season right into the grape belt as near to Northeast, in Erie County, as possible, and see for yourself just the methods of cultivation and spraying that are there practiced most successfully. The kinds of apparatus that are used, the methods of trimming and cultivating the vines, methods of making and applying the spray liquid, all are better learned on the ground where this is being done extensively than by any other means. In that region we never hear any thing of damage to grapes by bees, because they gather their grapes and market them at the proper time, which is before they are bursting with dead-ripeness. They also spray, and cause the skin of the fruit to be healthy, and thus there are no holes by disease germs where the bees find entrance.

You mention larger, stronger, and later foliage having been made on the vines during the past two years by the use of nitrate of soda. This is, no doubt, due to the nitrate, as I have seen such results on almost all plants where it is used. From 150 to 200 pounds per acre is the amount generally used on trees, vines, and, in fact, almost all forms of vegetation. It should be applied when growth starts in the spring, and again in about a month, but not continued after the early summer.

PROF. A. J. COOK, HORTICULTURAL COMMISSIONER OF CALIFORNIA

Something of the Life History and Doings of the Man who has been Asked by the Governor of California to Step up Higher

BY E. R. ROOT

For three or four issues back I have been telling something about the lives of eminent beekeepers who have ended their labors in this world, and who have gone to the great beyond. In this issue I have a more pleasing task—that of saying something about the life-work of a man who is still in the flesh, and who, it is to be hoped, will be with us many years to come. I refer to none other than Prof. Albert J. Cook, who has just been appointed Horticultural Commissioner of California. He needs no introduction to our older readers, for his contributions have graced these columns for many years.

For twenty-seven years Professor Cook was instructor and Professor of Entomology and Zoology in the Michigan Agricultural College. During the latter part of 1893 he was called to take a similar position at Pomona College, Claremont, Cal., where he has labored for 17 years more. By the way, long service anywhere always speaks well for any man.

During the latter part of last fall the California papers announced that Professor Cook, of Pomona College, was about to be promoted again—to receive the appointment of State Commissioner of Horticulture under Governor Johnson. Later on this appointment was duly confirmed. The Governor, in explanation, says he appointed Cook "solely upon his merits," and that "his position is one of the most important offices in the State." And as one of his co-laborers has well said, "this is the crowning event in Professor Cook's remarkable career."

No other man in the State nor in the country at large could bring to this particular work more clean-cut and indubitable fitness than Professor Cook."

Professor Cook will have placed at his disposal \$100,000 to carry on the work in his department, and the responsibility of appointing capable men to assist him is considerable, as the Governor says. When we consider the fact that California probably produces more fruit than any other State in the Union, and is destined to go still further, and that the keeping of bees is one of the big industries of the State, this appointment looms up large. Indeed, we doubt if there is another commissioner of horticulture in all the United States who has a larger field of work than our own Professor Cook. I say "our own," because he has been so closely identified with the beekeeping interests of the country. Himself the author of one of the most widely sold bee books, "The Beekeeper's Guide," a prolific writer for the bee journals, a number of times president of the North American and National

Beekeepers' Association—well, we have a right to claim him, as much as have the horticulturists of the country.

I think it is fair to say that Prof. Cook is distinguished, not so much for the great things he may have discovered in science (and he has done his share), but rather because he has been a great teacher. Hundreds of his students, some of whom have made their mark in the world, bear testimony to what he has done for them. He is loved and admired by his fellow-professors, and adored by his students, both at the Michigan Agricultural College and Pomona

Professor A. J. Cook as he appeared when he was conducting his experiments in bee culture at the Michigan Agricultural College.

College. The Pomona College paper, just received, is full of expressions of love and regret that he is to leave. I make just one extract:

The loss to Pomona College will be felt most keenly by all of the students who have known Professor Cook personally. His genial nature, his great heart, his tremendous and infectious enthusiasm, his keen interest in the personal welfare of every student under him—these things have made him greatly beloved by all. His interest in his students has never, through all the years, been a perfunctory one, but always a living, active interest, that went right out and fought for them; an interest that not only helped them to find their life work and get into it, whatever it might be, but ever afterward supported and encouraged them to great efforts. In a quiet way, unknown to the public, he has even financially assisted deserving students to complete their work, and for this he has been repaid in some things beyond the value of money—loyalty and love.

An indefatigable worker himself, he has the rare faculty of inspiring his students, and all those with whom he comes in contact, with his own habits of industry, zeal,

PROF. ALBERT J. COOK AS HORTICULTURAL COMMISSIONER OF CALIFORNIA.

and enthusiasm. His style of writing is natural and easy as well as fluent. As a lecturer he has few equals.

But Professor Cook is an original investigator. He has done much, both at the Michigan Agricultural College and Pomona College, to advance the cause of bee culture,

fruit culture, and horticulture in general. As a professor of Entomology in the Michigan Agricultural College he conducted a long series of experiments showing the very important and intimate relation between the bees and fruit. He had a number of the fruit-trees at the Agricultural College, just

as they were coming into bloom, covered with mosquito-netting. Some particular limbs were covered, while others were left to the visitation of bees and other insects. All of these experiments, showing conclusively the valuable work of the bees in pollinating fruit-blossoms when no other insects could or would be present, were published in the bee journals at the time, and, later on, were incorporated in more permanent form in the A B C and X Y Z of Bee Culture under the head of "Fruit-blossoms," and also under the head of "Pollen." While other investigators had done something similar to this, Professor Cook conducted his experiments on such an elaborate scale that he practically settled the matter for all time to come.

Again, we find him among the first to proclaim that honey is not evaporated nectar, as many had supposed. An elaborate series of experiments were conducted at the Agricultural College under his directions, the result of all which showed that nectar, after it has been gathered by the bees, is transformed or "digested" into a new chemical product known as honey. He also claimed that sugar syrup, if fed *thin* enough, would be transformed also by the bees; and from this arose a sharp controversy at the time, whether it was legitimate to feed bees sugar syrup and have them store it in sections and sell it as "honey." While Professor Cook never contended that it was proper to sell it as honey without stating that it was sugar fed, he maintained that it had the properties of honey, and, if fed *thin* as nectar, so that the bees could properly invert it, that it was "honey." This stirred up a "bees' nest" among the fraternity at large, and the stings that were jabbed into Professor Cook at the time were something fierce. While scientific men, including Dr. Wiley, admitted that there was a decided chemical change from nectar into honey, and that *thin* sugar syrup fed slowly to bees took on the properties of honey, they contended that the product *was not honey*, because the nectar of flowers has certain properties, including volatile oils, that are not found in sugar. The whole fraternity seemed to feel that the dogma of sugar honey was too dangerous to let go unchallenged, and the matter was dropped; but no one could or should question the honesty or sincerity of Professor Cook or those who stood with him on the proposition.

Professor Cook also took the ground that, as honey was a predigested food, it could be eaten by children and certain invalids, when cane sugars would do harm. In this, Professor Cook seems to have had considerable support, although there are some food experts who take no stock in this teaching. It is nevertheless true that not a few medical men are beginning to recommend honey in their dietaries; and recent issues of GLEANINGS have reported how honey is being given to convalescents at hospitals.

Whether Professor Cook is or has been always right on these propositions, I can not say; but I have always noticed that, when

some pioneers of science attempt to enunciate a new theory or truth, he often meets a storm of opposition. Galileo was pronounced a heretic, and put in prison for saying what we all acknowledge as an unquestioned fact. There have been many Galileos since, and there will be more to follow.

Later on, Professor Cook took an active interest in spraying fruit-trees to destroy injurious insects and fungi. Indeed, in the language of another, "the remedies he first recommended are now common; and he was probably the first to demonstrate the efficacy and safety of Paris green for the codling moth."

Again, we find that Professor Cook was one of the first to point out the danger to the bees and to the beekeeper from spraying trees while in bloom. He showed that spraying at such times is destructive to bees, and wholly unnecessary if not harmful from the standpoint of the fruitgrower. Later on we find him in the forefront advocating measures for the suppression of bee diseases, and Michigan was one of the first States in the Union to have a foul brood law. During all this time he was teaching entomology and zoölogy, and going around lecturing at farmers' institutes, telling the farmers how to grow more and better crops. After going to California he continued his active interest in bees, devoting himself assiduously to the work of his department.

During the last four or five years his writings have not appeared in the columns of our bee journals; for be it remembered he was approaching a time in life when he could not work night and day as he had done in his early career. But I find that, according to the college paper published at Pomona, he did much "to place his department in the college on the most efficient-working basis; and his services to the general public are warmly acknowledged by grateful men and women throughout the length and breadth of the State. His experiments in agricultural and horticultural matters have for many years been of a very extensive character. Taking all of these things into consideration, Governor Johnson could scarcely have found a man better equipped to undertake the duties of the new office, involving, as it does, an annual appropriation of \$100,000 and a corps of assistants."

Besides all his other qualities, Professor Cook is one of the most lovable Christian men I ever met. I have seen him in conventions, and time and time again he has, with that broad and loving spirit so characteristic of him, poured oil on troubled waters. He was, indeed, a great peace-maker, because he seemed to have the happy faculty of seeing the good in everybody, and of trying to make every one happy. It goes without saying, that Professor Cook will harmonize the apparently conflicting interests of the beekeepers and the fruitgrowers. If he has any thing to say about it (and he will have a good deal) there will be "no strife between me and thee, for we be brethren."

Fig. 1.—Tobacco farm of Fred M. Colton, Granby, Conn.

THE TOBACCO INDUSTRY IN THE CONNECTICUT VALLEY

BY E. H. SHATTUCK

The subject of tobacco honey may sound a little odd, and the average beekeeper in Connecticut who has not investigated the matter thoroughly is a trifle alarmed on finding out that the tobacco plant is being allowed to blossom, and, as a consequence, yield nectar; and many of them feel that it will spoil the flavor of the late summer and fall honey to a certain extent.

It is because of this feeling of unrest among the beekeepers of the Connecticut Valley that this article is penned, in the hope that it will reach, through *GLEANINGS*, a great number of the fraternity who live in the tobacco section.

During the past few years "syndicates" and well-to-do farmers have begun raising under cloth what is called "shade-grown" tobacco, and also have commenced "picking" the leaves from the outdoor tobacco, so called, in both instances allowing the plant to blossom and mature seed. Until these new methods were adopted all tobacco in the Connecticut Valley was topped, and the "suckers" picked off as they presented themselves, all blossoms thereby being headed off except, perhaps, a few plants in the field which were left to produce seed.

The tobacco plant is self-fertilizing, a large part of the pollen being used by each individual flower. When the grower wishes to have "pure" seed true to name he ties a large paper bag over the young blossoms; and as the stem lengthens out he passes along and pushes the bag upward to give

the flowers room to expand. In this way all insects are kept out, and the result is seed that is an exact counterpart of the parent plant—that is, the offspring is such. One might think that, so long as no insect is needed to fertilize the blossom, the chances of a secretion of nectar would be slim, as nature supplies it abundantly only to those plants that need the help of the bee to carry the pollen from one flower to another; but, as a matter of fact, a great deal of nectar is supplied in right seasons, and it is a help to have the bee visit the flowers to help disseminate the pollen grains; and it doubtless makes stronger and more fertile seed, as that is one of nature's strongest laws. I think the growers will find to their sorrow that the practice of raising seed under the paper bags, if long continued, will tend toward weaker and therefore less hardy and sturdy plants. Does it not sound reasonable? The tobacco expert, who raises "Shade Grown" for the leaf only, does not leave openings for the bees, as it does not matter materially to him. But in spite of all he can do, the fields are so large that numerous openings present themselves to the industrious little insects, so that more or less of the nectar is saved.

Remember the seed from these immense fields of tobacco is not saved. A small piece is arranged for, to cover the needs in this line.

The year 1912 will see hundreds of additional acres devoted to the raising of tobacco by these new methods, in Hartford County alone, as it has proved a very profitable crop, the leaf thus produced selling readily at advancing prices. This gives the beekeeper a new and increasing source of hon-

ey, and at a time of year when a dearth is usually on in this locality. The plant furnishes nectar between the buckwheat flow and the fall flowers, such as goldenrod, asters, etc., and is a heavy yielder in some seasons; but a cool dry summer, such as we have just experienced, stops the flow to a great extent. In 1911 there was very little honey of any kind produced in this locality. In 1910 the bees from my apiary swarmed on the tobacco, some colonies producing 100 pounds of surplus in sections. It will be several years before the value of tobacco honey is fully known; and whether this new source of nectar will eventually help or retard the Connecticut beekeeper, will be a question that will be decided in the near future.

I wish to emphasize especially the statement that our beekeepers have nothing to fear from the nectar of the tobacco plant. All the early section honey is ready to come off the hive before the tobacco commences to yield, and it has been quite the rule in Connecticut to let the fall flow go to the brood nest for winter food, and this new source will fill the bill exactly, helping out largely in seasons when fall flowers fail, or are cut by early frosts. The bees winter finely on the honey; and if any sections are made during this flow they will certainly sell as well as buckwheat, being somewhat lighter in color, and, for many uses, equal to any of the darker grades of honey, if not superior. If for any reason the beekeeper does not wish it to go into sections he can put on extracting supers and handle the product in any way he sees fit.

Connecticut does not boast of many large apiaries, under 20 colonies being the rule in

this locality; but if the tobacco plant continues to be raised and allowed to blossom, many more can be kept to advantage. More colonies have been lost during the winters for lack of supplies than any other one thing, as a good fall flow is the exception rather than the rule. If the new source will fill the brood nest for winter, bees will increase much more rapidly, and give the beekeeper more assurance of success.

Fig. 1 shows outdoor tobacco in full bloom owned by Fred M. Colton, of Granby, Conn. Mr. Colton's tobacco-warehouse for sorting the crop is seen in the distance. About 60 hands are employed in the place during the winter. Fig. 2 presents the tobacco blossoms near at hand. A remarkable thing about the flower is that a bee will disappear in the depths of the flower, and remain perhaps a full minute, and, upon coming out, fly straight home. It can readily be seen that a field of 100 acres or more will keep quite a few bees busy, with such a supply to draw from.

Fig. 3 gives an idea of the tents which are used to produce "shade grown" tobacco. Notice the splendid roadways that lead one through these vast fields, some of them being nearly a mile in length. These roads occur every little way in order that the harvesting may be the more easily carried on. A severe thunderstorm sometimes comes along, ripping the cloth off from hundreds of acres, giving the bees a fine chance to visit the bloom. But the tents are never "bee tight," so that they find a way in if the nectar is to be had.

People who have not visited the large tent plantations that have sprung up as if by magic can not realize the progress the in-

Fig. 2.—Close view of tobacco blossoms. The honey from this source is dark in color, but answers equally for winter stores.

Fig. 2.—Tobacco growing under cloth. Some of these roadways are nearly a mile in length.

dustry is making. I am not a party to the use of tobacco, and would not, if my way were law, promulgate the use of it; but it is here, and the honey part is certainly all right.

Granby, Ct.

HOW FRUIT MAY BE IMPERFECTLY POLLINATED

Spraying Trees in Blossom all Wrong, Even from a Fruitgrower's Standpoint

BY ARTHUR C. MILLER

We beekeepers are very careful not to permit the fruitgrowers to forget the importance of our bees to their business. We are not at all backward about reminding them of the sundry blunders and losses of some of their fellows in driving beekeepers from their vicinity, and then having to beg them to come back. We very diligently rub it in, for it gives us a deal of satisfaction to say "I told you so," and then you know it helps in a whole lot of nice little ways. These orchardists give some of us a nice spot for an apiary, a room or a building for storage, extracting, etc., sometimes do our carting, just so they may be sure of having the blossoms well pollinated.

Then sometimes we forget all about a crop of fruit-bloom honey. "Oh dear! no, we seldom get a crop of honey from apple blooms—perhaps only once in four or five years. Really it would be better for us to put the bees a couple of miles down the road. But as the bees are such a help to you, and you keep a sort of watchful eye over them, we are really very glad to help you out, even if we do get a little less honey."

And after all our pains to oblige and accommodate, some of those chaps every now and then get very skeptical about the usefulness of the bees to him. "Drat the confounded stinging bugs, they are a consarned nuisance. I got all the apples the trees would carry before you brought the pesky things here, and the sooner you take them away the better I'll like it."

Most exceedingly unreasonable, very shortsighted, and so annoying, too, after all the pains to which we have been to educate him to our point of view! Oh! well, he must be talked to again and shown his folly.

Here is a fine bit of evidence, good enough to convince him or any other fruitgrower. This photograph of an apple, cut horizontally in two, shows four seed vesicles with fertilized and perfect seed, while the fifth contains only the dead and dried ovules which were not fertilized. And the result of such non-fertilization is plainly seen in the surrounding pulp. The apple on that side is flattened. If two or three vesicles were in that condition the apple would be much more deformed; in fact, quite unmarketable.

"Now, sir, that is because the blossom was not fully pollinated. You go to work and plant hundreds and thousands of trees all in one great orchard, and the blossoms are numbered by millions. And, at the

same time, old Dame Nature has not massed the insects to do the work of carrying pollen. It is up to you to help her out; and the only way in which you can do it is to put a lot of bees there."

"The bloomers' bees are in the way when I'm spraying."

"Man, you're crazy to spray when the trees are in bloom. That spray, falling on the very sensitive stigma of the flower, partly or wholly ruins it, so that, even if pollen lodges there, it can do no good. A blossom only partly injured and then pollinated would give just such a sort of apple as shown. Furthermore, you are nowadays so confoundedly thorough in your work that

The result of imperfect pollination. Note the shriveled condition of the upper seed and the depression in the apple on that side.

seldom is there a spot on any tree not reached by your spray. Just do that when the trees are in full bloom, and you will be minus a crop of fruit that season. And here is the proof. One orchardist, spraying after the petals had fallen, came to one tree which, for some reason, was away behind the others, and was still in full bloom. To save himself the trouble of another trip, he sprayed it then, and nearly every little apple dropped off. Of the few which matured, there were not a dozen perfect ones."

We must not let the fruitmen lose sight of these facts. It is our duty to help them avoid loss, misfortune, and disappointment.

And, by the way, that fruit-bloom honey sold like hot cakes, and at a fancy price too—could have sold five times as much. Get after it, boys; it's a good thing.

Providence, R. I.

[As Mr. Miller says, the beeman should help educate the fruitgrower if he is ignorant of some of the fundamentals of his own business; for by so doing he helps his own business. Every beekeeper should know of the important work performed by the bees, for he is almost sure to encounter some small fruitgrower who may jump to the conclusion that bees are a nuisance rather than a benefit.—ED.]

HOW TO AVOID SPRING DWINDLING

A Scheme for Helping the Weak Colonies in the Spring to Hold their Own

BY WILL JENSEN

In the spring of 1896, after much loss and many sad experiences in losing weak colonies, I was almost ready to give up. I had tried to be successful by following the experiences of others, and I had read every text book that I knew of that had any thing to say about spring dwindling, but still my fine young queens were left with a mere handful of bees in their hives. While I was thinking the matter over, a plan occurred to me one day which I proceeded to try at once.

For every weakling that I had, I got ready an empty comb, a frame containing half a sheet of brood foundation, and a comb of honey. I put the empty comb by the hive wall, the frame with the half sheet of foundation next, and finally the comb of honey. After lacerating that one comb of honey so the bees would be bound to load up, I filled the rest of the hive with empty combs and closed the entrance so that only four bees could come out at once. In ten days I was surprised to see what wonderful progress these weak colonies had made; for on both sides of the foundation there was sealed brood. At this time I lacerated the comb of honey again.

If there is no comb of honey on hand, rip from a 2×4 , just the length of a frame inside, a piece two inches deep by the width of the topbar; bore this piece full of holes, starting the bit on one of the narrow edges but not boring clear through. Let the holes

be close enough together so that they will overlap. Fasten a half sheet of foundation to the bottom of this trough, and then fasten the whole thing in an empty frame, a bee space from the topbar. Bore a hole through the topbar for a funnel to use in filling the trough with syrup. Place this feeder frame with its foundation beneath between two empty combs in the hive, and always keep the feeder full.

For the last fifteen years I have saved 97 per cent of my weak colonies in the spring by this plan. The point is this: A very small cluster can not keep up the necessary heat if there is a

cold comb dividing it into two parts. Let this handful of bees cluster all together and you will be surprised at the results.

Beeville, Texas.

THE VALUE OF BEES AS POLLINATORS OF MELON BLOSSOMS

BY W. C. MURDIN

To my way of thinking, gardening and beekeeping should always go together. From the time the vines begin to blossom until the frost kills them, the bees work on them and we have more melons, citrons, cucumbers, etc., than we ever had before we started to keep bees. Last year our vines were all loaded; in fact, some of them had almost too much fruit, and I am sure it is on account of the bees pollinating the blossoms. The bees seem to work on every thing in the garden. Even potatoes, when they are in blossom, are visited.

I have heard complaints from some that bees will "eat" fruit; but they do not bother us in this way. We can not find that bees are troublesome in any way, in fact. Our garden is close to the main road where teams are passing only a few yards from the bees, but I have never heard of any one getting stung. I have found that bees are generally harmless if left alone.

In my work around the hives I have never used a smoker. When I want to do very much work, such as extracting, etc., I select a time when the weather is warm and the bees good-natured. I use gloves and an Alexander veil, however. This veil, by the way, I regard very highly. It is nice and cool, is good protection, and yet one can see easily to do any kind of work.

Apiary and orchard of C. Koppenhafer, in the village of Brownhelm Center, Ohio.

I think that white clothing annoys the bees less than darker-colored fabrics. I have made observations for a long time to determine this point, and I find that the bees do not get stirred up as easily when I have on a white coat. One day last summer Mr. J. Boyd, who has his bees also in this garden, was with me; and while I received no stings, the bees kept stinging his black felt hat.

Gladstone, Manitoba, Canada.

[We are sure you would find it easier to work with your bees if you used a smoker. It is not necessary to blow smoke over the bees continually; but very often a little whiff of smoke at the right time prevents a general uprising, and enables the operator to go right on with the work without letting the bees find out they can have things all their own way.—Ed.]

BEEKEEPING AND FRUITGROWING

BY C. KOPPENHAFER

I have a fruit farm of $7\frac{1}{2}$ acres in the village of Brownhelm Center, located among the trees as shown in Fig. 1. There are over forty colonies of bees which I find a great help in fertilizing the fruit-blossoms. In 1910 I secured \$200 worth of fine honey from 23 colonies, spring count.

Some of my neighbors across the street are making me a lot of trouble, and threatening to compel me to get rid of my bees. I am not able to make them believe that the bees do not spoil their fruit, nor that they are of any benefit in the spring in fertilizing the blossoms. One man in particular said it was an imposition to the neighborhood to have the bees there; and if there was any

Mr. and Mrs. C. Koppenhafer and their family of honey-eaters.

law to make me dispose of them he would take advantage of it. However, for all that we are friends so far as I know. He was exasperated only when the grapes and plums were ripe. For a few days at that time the birds were very bad; and as the bees had nothing else to do, they of course were troublesome. I have over forty plum trees myself, and also some grapes, and I know well enough that it is not the bees that do the mischief. It is also claimed that the bees damage the peaches; but I have my bees right in the peach orchard, and I find that they never work on any except the pecked or decayed ones. I picked all of my peaches without a veil, and never get stung.

The other illustration shows you my family of honey-eating boys. I think the use of honey in the home avoids many a doctor bill. My wife is also of the same opinion. She takes great interest in the bees, and often hives swarms when I am not at home. Amherst, Ohio.

BEES AND ORANGES

BY J. SLIGER

My apiary is located on benches above the ground, because I have a weak back, and I can handle the frames more easily if the hives are up a few inches. In the spring of 1910 I began to build up the apiary and increased from ten to thirty-eight colonies. I intended to paint the front of every other hive green; but other work crowded me so that I neglected it, and, in consequence, I lost a lot of queens which, in returning from their flight, went into the wrong hives. That fall I united until I had twenty colo-

nies, and last spring I increased these to forty-eight colonies.

I have a fruit ranch of twelve acres—ten acres of oranges and about two acres of apricots; but I intend to take these out and put in oranges. I have raised berries of different varieties, but I am taking these out to put in oranges. I have found plenty of work to keep a man of sixty-three years busy.

Redlands, Cal.

THE MISREPRESENTATIONS OF LAND SHARKS AND THEIR VICTIMS

The Truth about Wharton County, Texas

BY W. H. MOSES

Many northern people are being persuaded to come to the coast country of Texas through the misrepresentation of land agents and others who hold out great inducements to homeseekers, offering them land at about \$45.00 per acre, one-fifth cash and one-fifth per year without interest or taxes, telling them that they can grow two or three crops a year, each worth \$150 to \$200 per acre, and that they can grow oranges, grapefruit, and other things that belong to tropical countries; and that the temperature seldom goes as low as 40.

I have lived here in Wharton County since 1887, and have never seen a winter pass without a freeze. Here is a cold-weather record I have kept: 1899, Feb. 11, began to snow at 2:30 P.M.; temperature 22 at 6 P.M.; 18 at 7 P.M.; Feb. 12, zero at 8 A.M.; Feb. 13, 4 above at 7 A.M.; ice three and one-half inches in a tub in the yard.

Nov. 3d and 4th, first frost that fall.

1905. — Feb. 2, rained. Norther came up at 2 P.M.; 3, rained; cold north wind; 4, rained. Temperature 30 at 12 P.M.; 5, rained; 32 at 7:30 P.M.; 12, rained last night; north wind this morning; temperature, 36 at 7 A.M.; 26 at 9 A.M.; 24 at 11 A.M.; 22 at 2 P.M.; 20 at 6 P.M.; 13, temperature 16 at 7 A.M.; 14, temperature 20 at 7 A.M. The lake froze over hard; will hold me up (175 lbs.). March 20 and 21, frost; temperature, 32—34.

1907.—One rain in January; one rain in February; one frost this winter — the warmest

J. Sliger's apiary, Redlands, Cal., which he runs in connection with an orange ranch.

Summer home of S. Geo. Stevens, surrounded by the birds, the flowers, and the bees.

and driest winter in 20 years. Bees gathered pollen Jan. 8. March 15, bees very strong.

1909.—Jan. 31, no rain since Dec. 20. Only one freeze and three frosts this winter.

Feb. 14, norther struck at 12 M. Temperature, 56; 32 at 7 P.M.: 15, 20 at 7 A.M.; 20, bees suffered a great loss in young brood.

1911.—Jan. 1, bees gathering pollen today. Temperature 65 at 10 A.M.; 2, cloudy north wind; 30 at 10 A.M.; temperature 24 at 4 P.M.; 3, 12 at 7 A.M.; June 13, temperature 110 at 2 P.M. on my porch.

1912.—Jan. 11, temperature 60; bees flying nicely; 12, north wind blew last night, about 8 P.M.; temperature, 18 at 11 A.M.; 13, temperature 10 at 8 A.M. Ice one and one-half inches thick on canal at Lane City.

The boys are having a fine time on the ice. Two boys from Ohio think it is fine, but both broke the ice and went into water about two feet deep.

Lane City, Tex., Jan. 14.

LIVING CLOSE TO NATURE

BY S. GEO. STEVENS

Our first swarm of bees came to us in July, 1910; and, not knowing much of bees, I divided them and made two colonies. In the fall I took 50 lbs. of surplus comb honey from them, and wintered them in good shape on their summer stands.

This summer we made ten colonies of them with some little help from other bees I bought in August, and this fall I got about 100 lbs. of honey, and all the hives were in good shape for winter—no feeding. With what I bought we have 32 colonies in all, and will winter them on summer stands.

We have about our cottage a sort of combination of insect and bird life, in both of which we are very much interested. We feel that our first colony of bees was largely the cause of our interest in the birds.

Duluth, Minn.

[Our correspondent is a great friend of the birds, and he has tamed them until many of them will fly from the trees to eat from his hand. He has done a vast amount of good in writing articles for the press, condemning in no uncertain terms the boys and men from the cities who take a fiendish delight in killing "these creatures who come to live with us, and who make life just that much more worth living."—Ed.]

THE RIPENING OF NECTAR

Does the Body of the Honey Vary According to the Humidity of the Season?

BY T. P. ROBINSON

Arthur C. Miller, page 23, Jan. 1, tells how bees ripen nectar. I am not particularly familiar with the bee's way of depositing her load in the cell; neither do I know that bees ever take up this nectar again except to deposit it in a more convenient place. But I doubt very much whether they make a practice of taking it up for the special purpose of curing it; and my doubts are based on the fact that the body of my honey varies just as does the humidity of the season. This variation in body is further due to the strength of the colony.

I have known many times when the evaporating or drying out of the water was almost entirely omitted, and the honey soured in the

The three best industries of Pecos Valley, New Mexico, fruit, bees, and alfalfa.

combs. I have known this souring to be so bad that the combs would "burst" in the hive and the honey would run out freely. But these extreme cases have been largely confined to weak colonies. It is certain that the bees were bent on gathering all the nectar possible during the day, and were not numerous enough to fan it dry at night nor to create sufficient heat.

THE FIELDERS DEPOSIT THE HONEY IN THE CELLS.

In the editor's footnote, p. 24, Jan. 1, he says that it has been repeatedly stated that bees on returning from the field do not deposit their nectar directly in the cells, but pass it around to bees in waiting which cure it before depositing it. Allow me to give contradictory evidence.

Five years ago I had a yard of 100 stands of bees without food, and on the point of starvation. It had been raining for eight days, and all the colonies had been kept indoors. The weather had been dry for five weeks previous, and for ten days before the rains the bees had been gathering just enough honey to live on day by day. Brood-rearing had entirely ceased. I was watching, and was in readiness; but hoping that the weather would become fair I delayed feeding as long as possible.

I observed that the bees were carrying out their last cells of drone and worker brood, for they had a little; so I took 25 pounds of sugar and 3 gallons of water and made a thin syrup, placed it out for the bees, and in 30 minutes it was all in the hives. I made an examination 35 minutes after placing out the food; and what did I see? I found this fluid in varying amounts in the cells in the brood-box from the deformed cells on the top bar to the imperfect cells on the bottom bars. The sole idea of the bees seemed to be to get the stuff in the hive.

That night a great humming was heard, for it was in May. Now notice! Twenty-four hours later the queens had begun to lay, and this nectar in the meantime had been

gathered up and placed in proper rings for the brood nest just above the eggs.

The next day, 48 hours after the first feed, I gave them 1 lb. a colony instead of half a pound, as at first, and the bees made a worse scattering of it in the hive than before, but by the next day all was gathered up and placed in proper order. No, bees do not pass the stuff around, but deposit it at once and go for more.

It doesn't take much of a shake to scatter new nectar all over, then if combs are tilted too much the nectar will run out on the ground; but it tastes unlike honey, being watery and of strong flavor.

DO BEES "ROAR" WITH THEIR WINGS?

Mr. Miller doubts whether the great roaring could be caused by the wings of one colony of bees. I emphatically disagree. A good swarm of bees on the wing (and the bees do not all go with the swarm) can be heard plainly 100 yards away on a still day; but the hum of a colony at night would not seem so loud 50 ft. away.

Bartlett, Tex.

[That laden bees give their loads to *other* bees was not our statement, but an old current notion. We merely mentioned it in our footnote as an illustration of how old theories have to give way to later and more careful observation. Your statement on the point supports that made by A. C. Miller, which is doubtless right.—ED.]

A 200-COLONY APIARY IN A NEW MEXICO ORCHARD

BY J. S. HIGH SMITH

The illustration shown herewith is a picture of my apiary of 200 colonies of fine Italian bees. In 1910, by the 1st of September we had over 8000 pounds of surplus comb honey from alfalfa, which was very fine, being clear and white. I began with only a few colonies in the spring of 1908.

The picture represents three of the best products of Pecos Valley—honey, fruit, and alfalfa. The apiary is in a small four-year-old apple orchard and is surrounded by fields of alfalfa.

Artesia, New Mexico.

THE HONEYBEE AS A FERTILIZING AGENT

BY DR. E. F. PHILLIPS

The honeybee is known widely as the producer of honey, and it is recognized that this makes it one of the minor agricultural animals. The total value of the crop produced is not fully realized, and it is often a surprise, even to well-informed beekeepers, to learn that the average annual honey crop of the United States is worth about \$20,000,000. The American farmer produces crops of such gigantic proportions that a branch which can not be discussed in the millions is scarcely worthy of consideration. Even in this galaxy of wealth the honey-producer has no reason to be ashamed of his specialty, and he may be further congratulated on the fact that his field is just beginning to be occupied. We can not yet foresee an overstocking of the country, and an overproduction of honey will not take place until we are producing at least ten times what we do now.

The subject which is here announced at this time does not, however, deal with the direct benefits which accrue to American agriculture through the offices of the honeybee, but to what may be styled the indirect benefits. These are recognized by specialists, but are passed over unnoticed by the average farmer or citizen, and it is to recount the indirect benefits that this subject is assigned.

POLLINATION OF FLOWERS

As is well known, blossoms, before they set, must be pollinated. That means that pollen from the anthers, or male portion of the flower, must reach the stigma, or female portion. Different plants exhibit wide variation in the arrangement of these parts, and it may be well to recount some of these different plans. In some cases the male and female organs are in separate flowers, as in the case of corn, the male flowers being the tassel and the female flowers resulting in the ear. In other cases the types of flowers are borne on separate plants, as in the case of the mulberry.

In the majority of plants, both anthers and pistils are found in the same flower; but even here an extremely wide variation is found. In some cases the anthers ripen earlier than the pistil, so that the pollen produced is ineffectual in producing fertilization of that particular flower. This is shown in the fireweed, or willowherb, which is an important honey plant, especially in Northern Michigan. The reverse condition in which the stigma matures first observed in the common figwort *Scrophularia*

nodosa, and to some extent in horse chestnuts.

In other cases, the anthers and pistil mature at the same time; but because of their relative position, self-fertilization of the blossom does not occur. Other arrangements of this kind might be mentioned; but enough has been said to indicate that flowers are often so arranged that self-fertilization is impossible. In some cases of pears and plums it has been shown that the pollen is ineffectual in fertilizing the flower, even if placed on the stigma. These arrangements all confirm the popular belief in the dangers of close inbreeding, and point to the desirability and often the necessity of cross-fertilization.

Fertilization of plants occurs in two general ways. Plants like willows, pines, oaks, and birches, and, in general, plants whose flowers are inconspicuous and often not even recognized by the layman as flowers, are so constructed that pollen is carried by the air currents from the anthers to the pistil. The pollen of such plants is light and dry. Most flowers, however, are not of this type, but require some agent to carry the pollen, and these agents are usually insects. Without the kindly offices of insects which are despised as an order of animals by the majority of people, our fruit crops would cease to be, and the flowers which abound would no longer bloom.

RELATION BETWEEN PLANTS AND INSECTS

It may also be said that plants have a greater appreciation of insects than we have, for we see the most wonderful arrangements for attracting insects to the flowers so that their visits will result in cross-fertilization. The pollen is not intentionally carried and put in the right place, but is transported on the hairs or otherwise as the insect goes from one flower to another. Insects go to flowers to gather pollen or nectar to be used as food at once, or to be removed and stored, as in the case of the honeybee. Pollen is produced in such abundance as to act as an attraction to pollen-feeding insects, and still leave a sufficient quantity to insure proper fertilization. Nectar acts also as an attraction, and probably serves no other purpose to the flower.

The question of what insects are most important in carrying pollen has not been sufficiently investigated. In the comprehensive investigations of Müller, he found that in low Germany 2750 out of 6231 visits of insects to flowers observed were made by *Hymenoptera*, and of this number 2191 were by *Apidae*, the family to which the honeybee belongs. He frequently refers to the fact that on some plants the honeybees and bumblebees play "by far the most important part in fertilizing our (German) indigenous flowers." Waite, in his bulletin on "The Pollination of Pear Flowers" (Bul. 5, Div. of Veg. Pathology, U. S. Dept. Agr.), mentions a large number of species of insects which visit pear blossoms, but says: "The common honeybee is the most regular and important abundant visitor, and

probably does more good than any other species."

In an article read before the Ontario Beekeepers' Association in December, 1900, by the late Dr. James Fletcher, he said: "It can be shown that, owing to its size, weight, and habits, no insect is so well calculated to ensure the fertilization of fruit-blossoms as the honeybee, which flies rapidly from plant to plant, and, by running over the flowers in search of pollen or nectar, brushes off the pollen and carries this vitalizing element on the hairs of its body to the next flower visited. The habit of the bees, which has frequently been noticed, of confining the visits, when collecting largely to the same kind of plant, is taken advantage of by the beekeeper to store up at certain seasons particular kinds of honey, such as apple, raspberry, basswood, clover, and buckwheat honeys. This habit is also manifestly advantageous to the plants on account of the pollen which is carried by the bee being of the kind necessary for the fertilization of its flowers, which could not be affected if the pollen were that of some other kind of plant."

In some work done at the Michigan Agricultural College it was shown that, of all the insects collected on apple trees in bloom, none were so abundant as the honeybee. On the other hand, similar collections made at the Connecticut Experiment Station at New Haven showed very few honeybees. The latter results may be explained by the fact that, in the preceding winter, over seventy-five per cent of the colonies of honeybees in that section of the country died, and by the fact that bee diseases had probably further reduced the number of bees in that section, as they are abundant in that State. Moreover, we should not expect to find many bees in a city on the seashore. The growing of cucumbers under glass is an important industry in Eastern Massachusetts and in other parts of the United States. The Massachusetts cucumber-growers annually use about 1000 colonies of bees in their greenhouses to pollinate their blossoms, in place of the former method of pollinating by means of a camel's-hair brush.

While the honeybee is, perhaps, no better equipped than other insects, especially other bees, for carrying pollen, there is one respect in which it outranks all others as a valuable asset to the fruitgrower. We are not able to propagate other insects in quantity, and introduce them to orchards at the proper time; but it is a very simple matter to carry in colonies of bees to insure a crop, if the weather is fit for bees to fly. Many orchardists realize this, and keep bees solely for the benefits derived from cross-fertilization of the fruit-blossoms.

COMMON INTERESTS OF THE BEEKEEPER AND FRUITGROWER.

The interests of the beekeeper and of the fruitgrower are identical. In the past there has arisen from time to time bad feeling between these two classes of farmers. The fruitgrower claims that the bees destroy his ripe fruit; but this has been entirely dis-

proven. Bees never suck ripe fruit unless it is previously punctured by birds or insects, such as wasps, or unless it is decayed. On the other hand, the beekeeper claims that the fruitgrower sprays his trees while they are in bloom, thus killing the bees. This procedure is not recommended by any entomologist, and is not practiced by well-informed orchardists. It is prohibited by law in New York and in some other States. Cases of this antagonism are still to be found, but they are becoming more and more rare. Let us hope that the time will soon come when the beekeepers and fruitgrowers will meet in common conventions to discuss their problems in common.

The production of the millions of dollars' worth of fruit in the United States depends largely on insect pollination; and no insect is so important in this work as the honeybee. It is a most conservative estimate to claim that the honeybee does more good to American agriculture in its office as a cross pollinator than it does as a honey gatherer.

Washington, D. C.

HOW POLLEN IS COLLECTED

The Part Played in the Process by the Auricle

BY F. W. L. SLADEN, F. E. S.

The pollen dust gathers on the body hairs of the bees as the result of the visits paid to the flowers. These hairs, as seen under the microscope, are branched, and therefore are admirably adapted to hold the pollen.

In the bumblebee (and probably also the honeybee) the pollen dust in the hairs on the thorax is collected on brushes on the inner sides of the metatarsi, or basal joint of the foot, of the *middle* pair of legs, which are moistened with honey from the tongue to make the dust cohere. The pollen dust in the hairs on the abdomen is collected on brushes on the inner sides of the metatarsi of the *hind* legs, and this is probably moistened by rubbing the hind legs together.

After this the pollen is transferred to the corbicula (or pollen-basket) on the tibiae of the hind legs, where, as every one knows, it accumulates into a great lump as the result of repeated contributions from the metatarsi. But how does it get there? It is evident, as Cheshire observed, that the pollen on the right metatarsus is transferred to the left corbicula, and the pollen on the left metatarsus is transferred to the right corbicula. Cheshire supposed ("Bees and Beekeeping," 1886) that the metatarsus discharges its pollen on the corbicula by scraping its brush on the upper side of the tibia; but I find that this is not the case. The pollen is scraped off the metatarsal brush by a comb (*c*) situated at the end of the tibia on the inside, and it passes into a small concave receiver (*d*) that joins the comb; then, when the leg is straightened, a projection on the metatarsus called the auricle (*e*) closes upon the receiver, compresses the pollen,

and at the same time forces it out to the lower end of the corbicular, which is here slightly depressed and almost devoid of hairs. The compression of the pollen in the receiver is an essential part of the process; for loose pollen grains such as occur on the metatarsal brushes would not hold together in the corbicular. In the bumblebee the angle between the surface of the receiver and that of the corbicular is obtuse, and the compressed pollen easily passes from the one to the other; but in the honeybee there is a sharp angle at the corner, and the auricle bears a fringe of hairs (*f*) to guide the stream of pollen to the corbicular; also the honeybee's auricle is evidently pressed back by the pollen, for it has no other means of escape.

Fig. 1.—Juncture of tibia and metatarsus in hind leg of worker honeybee, outer side.

Fig. 2.—Diagrammatic section of the same, showing mode of conveying pollen.

a, metatarsus; *b*, tibia; *c*, comb; *d*, receiver for pollen; *e*, auricle; *f*, fringe of hair on auricle.

I forced a queen bumblebee to relax, and, after placing some pollen obtained from a comb taken out of one of my hives in the receiver, I straightened the leg. The pollen was immediately delivered to the corbicular. I was struck with the freedom of action of the joint, and noticed that the auricle could be placed in the receiver in various positions, so that it can not only compress pollen there, but it can scrape out the receiver, and, on the other hand, can deliver the pol-

len high up on the corbicular. In the honeybee the joint works still more freely. The fact that, in the bumblebee, the pollen always begins to collect at the apical end of the corbicular, is now clear, and we see why the corbicular is so smooth and bare, for the pollen actually slides up it.

It is a significant fact that, although the corbicular is surrounded with a fringe of stiff hairs which act, as Cheshire observes, like the stakes that the farmer places round the sides of his wagon when he desires to carry hay, this fringe is interrupted at the spot where the receiver discharges its pollen on the corbicular. In the bumblebee the entrance here to the corbicular carries only about three stiff hairs. These hairs are short

and upright, and widely separated from one another, and are some little way inside the entrance. It is evident that their function is to provide a means of attachment for the pollen until the lump has grown large enough to be enclosed between the hairs at the sides of the corbicular. The entrance to the corbicular, in the bumblebee, densely dotted with fluff (under the microscope mossy hairs) which also probably help to hold the pollen. In the honeybee there are no stiff hairs, and very little fluff in the entrance to the corbicular.

In the honeybee the long hairs on either side of the entrance to the corbicular form a wide and shallow arch over it. The object of this arch is, no doubt, to help to support the lump of pollen on the corbicular without interfering with the passage of fresh pollen to the corbicular. The arch also helps to guide the pollen to the corbicular. In the honeybee the arch is less pronounced, and consists chiefly of hairs from the lower side, and these are so long as to

stretch almost across the tibia.

These facts add an interesting page to the wonderful story of the bee that is not given in our text books. How often have we seen the bees humming around the flowers, busily scraping their dangling legs together, and every now and then giving them a little jerk! At each jerk a minute quantity of pollen is tucked up on the corbicular.

On examining the workers of several spe-

cies of *Melipona* from South America in my collection, I notice that, although they possess a very wide corbicula and a comb, the auricle is absent, and the metatarsi are extremely narrow at the base. Apparently, therefore, in these bees, the pollen is not compacted, but is scraped on the corbicula by the comb in a loose state, and the corbicula bears a beautiful rack, like a long-toothed comb, to retain it. The shape of the metatarsus in some species, however, suggests that it may be bent up so that its upper edge presses against the end of the tibia to form a pollen-press.

In the solitary bees there is no corbicula, the pollen being conveyed on brushes situated either on the hind legs or on the under side of the abdomen.

SOME SPECIFIC OBSERVATIONS; HOW HONEY IS MADE USE OF.

On Feb. 11, a mild and sunny day, my bees were working busily on the winter aconite, *Eranthis hiemalis*; and by watching them I was able to verify my opinion as to how the pollen is gathered as mentioned above. I watched one bee for over five minutes, rifling flower after flower. During this time its loads of pollen increased in size considerably; but it did not once cross its hind legs, rubbing the metatarsal brushes on the edges of the opposite tibiae, as Cheshire supposed, although it frequently rubbed or scraped the inner sides of the metatarsi against one another, the *motion being always longitudinal*.

I noticed that the pollen dust was gathered direct from the anthers on the metatarsal brushes by the bee crawling about among the stamens and digging its legs in among them. In large open flowers, such as the winter aconite and the blossom of the apple, cherry, and plum, the anthers of which are accessible to the hind legs, the pollen dust is probably always gathered in this way, namely, direct upon the metatarsi.

But what makes the pollen dust cling to the metatarsal brushes? If a lump of pollen from the corbicula of a bee be examined, it will be seen that it consists of pollen grains made into a paste with some liquid; and if the lump be tasted it will be discovered that this liquid is honey. Obviously, the metatarsal brushes are moistened with honey, and so the pollen dust adheres to them. It seems plain, too, that the honey comes from the tongue. But though I watched my bees carefully I never saw them lick their hind metatarsi, and I do not think that the tongue could reach the hind metatarsi. Indeed, the only way the bee could convey honey from its tongue to its hind legs would be through the agency of the fore and middle pairs of legs. The tarsi and metatarsi of the fore legs are covered with stiff bristles, which are adapted to receive the honey, and the metatarsi on the middle legs are provided with brushes of stiff bristles which are similar. In watching the bees working on the winter aconite I saw their middle and hind metatarsi rubbed together on several occasions, and,

in several bees I killed, the brushes on the fore metatarsi were saturated with honey. But this rubbing of the middle and hind legs together was seen to take place far too seldom (namely only three times during the whole of my observations, which lasted, I should think, nearly half an hour) to moisten effectively the pollen grains, and thus I am led to conclude that the moistening of the hind metatarsi is generally carried out during the flight from flower to flower. Indeed, if one thinks of it this flight provides a most suitable interval in the work of the proverbially busy bee in which to discharge this apparently most necessary duty; and the bee, by acquiring the instinct to moisten its metatarsi, then would be able to do it mechanically, just as often as it is necessary. One must remember, too, that, during flight, the legs are free.

I must ask for the indulgence of the reader in dwelling so much on what I imagine, and so little on what I have actually seen; but this is a case in which the movements made by the bee are too quick to be followed by the eye, and I think that an examination of the pollen-collecting organs, a study of the bees in the flowers, and the following of my argument, will bring conviction that the process of pollen-collecting is very much as I have described it.

Ripple Court Apiary, England.

NEW LAW ON SPRAYING IN OHIO

What to Do if an Orchard is Too Large to Spray all the Trees when they are Not in Bloom

BY N. E. SHAW

Chief Inspector Division of Nursery and Orchard

[We wrote Prof. Shaw regarding the new spraying law in Ohio, and his reply follows.—Ed.]

The new law does not become effective until May 31 of the present year. Spraying is required between the 1st of November and the 30th of April. This is for the destruction of scale insects; and any solution which is used for this purpose can not be applied after foliage has appeared or buds have opened, because of the injury that would result. The material used for these applications would of necessity have to be the lime-sulphur wash, miscible oil, or some similar solution, and not an arsenical poison.

I have received many inquiries from bee-men concerning the spraying of fruit trees while in bloom. Most of them are under the impression that there is a law in this State against spraying at this time; but, of course, such is not the case. Neither the Experiment Station at Wooster, the College of Agriculture, nor this department, all of which send out a spray calendar, advocate spraying when trees are in bloom. In fact, we lay stress upon the fact that no application should be made at this time, but after the blossoms have fallen, or at least most of them. Recently one of our large commercial orchardists, whose acreage is too

large for his spraying equipment, made the statement that he intends to begin spraying for codling worm before the blossoms have begun to fall, in order to cover his entire orchard in proper time.

I called his attention to the fact that he would, no doubt, receive considerable injury from such an application, to which he replied that it was about six of one and half a dozen of the other; because if he did not get over his entire orchard the unsprayed part would be of no use to him.

I told him that, if his plan were very generally adopted, it would probably lead to the passage of a law prohibiting spraying at blooming time. I do not think that, should he undertake to do this, he will be very generally followed by others, because most of them have suitable spraying equipment for their needs; and while this man has been looked up to considerably in the past, and has had his methods copied by others, he does not hold the same place as an orchardist in the estimation of others at the present time.

I assure you I shall be glad to do whatever I can to enlighten our fruitgrowers on this matter, and hope that we shall never need a law to prevent spraying while trees are in full bloom.

In regard to this compulsory-spraying law I will say that the same is not under the control of this Division, and we are in no wise responsible for its passage.

Columbus, O., March 1.

ARE HONEYBEES OF ANY VALUE TO THE ORCHARDIST?

How Many Colonies are Needed per Acre of Fruit?

BY BENJAMIN W. DOUGLASS

The Greenhorn had just purchased a small orchard and had started out as a full-fledged convert to the "back-to-the-soil movement." Unlike many such greenhorns, he did not consider that he knew all there was to be known about farm and orchard work. He knew enough to know that you can not learn horticulture simply by reading books in the back parlor, and that fruitgrowing requires more than a theoretical knowledge in order to make it a success.

Since I had known the Greenhorn for many years it was but natural that I should be asked to contribute my share of information toward making the new orchard a success, and I accordingly made a careful inspection of his place soon after it was bought. This was in the spring of the year, shortly after the apple trees had blossomed—and they had blossomed lavishly. To the owner's surprise, however, the stand of fruit was exceedingly poor, although there had been no frost to injure the flowers.

"It seems to me," said I, "that your only trouble here is a lack of pollination due to the absence of bees."

"But," he replied, "I have a colony of

bees up under the grape-arbor at the house, so that surely can't be the reason for the trouble."

So I had to analyze the situation for him; and, briefly, this is what I said:

"Your house and the single stand of bees are nearly a quarter of a mile from the main part of this orchard. The past weeks have been very wet and cold, although not cold enough for frost. The hours of sunshine have been very brief; and during the period when the trees were in bloom the sun shone for only a few minutes at a time. Bees will not fly in such weather, or at best they fly but a short distance from their hives. Consequently your crop has failed because you did not have numerous colonies of bees scattered through your orchard. If you had done so the bees would have taken advantage of every minute of sunshine and given you a full crop where you now have a failure. If my theory in this is correct we should find that your trees near the house, in the 'family orchard,' have more fruit than these in the main orchard."

We at once investigated, and found that the trees near the house had set a very fair crop of apples. In the main orchard there were more apples near the house than there were on the further side of the orchard; for, as I have said, in that part the crop was a failure.

"Well," said the Greenhorn, "how many colonies of bees should I have on my twenty acres of orchard? and how close together should they be placed? or should they all be placed in one spot, such as the center of the tract?"

Here was a question that I could not answer with any degree of finality. It is impossible to draw a definite conclusion regarding the exact number of bees that should be kept in order to assure good pollination. Some seasons very few bees will suffice, while it is possible to imagine a blossoming season when *any* quantity of bees would fail to provide pollination. After a long series of observations on this subject I admit that I am still almost as far from a definite conclusion as I was at the start.

In the spring of 1911 I assigned one of my assistants to a study of the insects concerned in the pollination of the apple, pear, and cherry. Without going into his results in detail I will quote from field notes made at different times during the season:

April 20.—Warm and clear. An abundance of wild bees, and flies of various species. Honeybees present in large numbers.

April 22.—Partly cloudy; cold and windy following a rain; native species of bees and flies very scarce; honeybees fairly common.

May 9.—Warm and clear. Many small native bees on cherry; in numbers they exceeded the honeybees. On the apple the honeybees were the most numerous, exceeding all other species. Syrphid flies were quite common throughout the orchard.

These notes and studies were made in an orchard where there were about seventy col-

onies of bees. Comparative notes made on other orchards in the vicinity on April 22 showed that very few honeybees were to be found. This proved conclusively that the presence of the apiary in the orchard was of material value in securing pollination.

There can be no rule as to the definite number of colonies that should be kept for each acre, because of several variable factors which enter into the problem. In the first place, individual colonies of bees will vary, not only in strength, but in the aggressiveness of the members of the hive. Some colonies will range better and cover more ground in unfavorable weather than other colonies. The main difficulty, of course, is due to the fact that no two seasons are exactly alike, and the number of colonies that would be satisfactory one year might be totally inadequate the next season.

During an unfavorable season a large number of colonies close to the trees may insure a full crop when all the other trees in the neighborhood fail. This was repeatedly shown in the orchard of Mr. George S. Demuth, at Peru, Indiana. Mr. Demuth was primarily a beekeeper, and his apiary was located in a small orchard. Year after year this orchard set a full crop of fruit, even in cold rainy seasons when the neighbors all thought that the fruit was killed by frost. It is quite probable that no small part of the frost-killed fruit is simply injured by a lack of pollination. It is certainly true that fruit that is well pollinized is more vigorous, and consequently more resistant to insect and fungous injury, later in the season.

To return to the Greenhorn. With a persistence that was most aggravating, he insisted that I had avoided his direct question as to the number of colonies that he should keep per acre, and how they should be spaced. In answering this direct question I will simply say that, for my own use, I am intending to keep bees in the orchard at the rate of one colony for each two acres of orchard. For 140 acres of orchard I plan to have 70 colonies. These will not all be kept in one place, but will be divided up into groups of ten or fifteen each, and will be placed at advantageous points about the orchard. I would avoid stringing the hives over a great space in the orchard, as there are some men who are afraid of bees, and there may be such a man in one of your gangs at spraying time. If the bees are bunched in one small locality the trees around them can be left unsprayed until late in the evening, and the work can be done after the bees are through flying. Under no circumstances should the trees right around the apiary be neglected because of the bees. In fact, they soon become accustomed to having people around them, and it is seldom that they cause any trouble.

SOME MISCONCEPTIONS ABOUT SPRAYING

Every season we have any number of accounts of how some farmer has killed all the bees in his neighborhood by spraying his fruit. Sometimes such a report is true. In the great majority of cases, however, it

is not. When the practice of spraying first came into use a number of years ago, some manufacturers of spray-pumps published the directions for spraying in such a way that many farmers were led to an incorrect notion of the process. From this first misinformation has come much trouble, and many explanations have been needed to clear matters up between the fruitgrowers and the beekeepers.

As a matter of fact, the interests of the fruitgrower and the beekeeper are identical in many respects, and there is no cause for any misunderstanding between the two industries. Many fruitgrowers are seeing the value of bees in the orchard, and many beekeepers are beginning to realize the value of the honey harvest from the fruit bloom. No fruitgrower who pretends to know the first thing about spraying will attempt to spray his trees while they are in bloom. To do so would not only injure his friends the bees, but would also result in some actual damage to the blossoms.

WHEN TO SPRAY

The first spraying should be applied before the buds open, at a time when the bees are not interested in the trees in any way. The second spraying comes *after* the petals have fallen; also a time when the bees are no longer interested in the orchard. Bees attend very strictly to their own business; and after the nectar has dried up in the flowers they are a dead issue so far as the honey-gatherers are concerned. It is the second spraying that usually causes the fight between the orchardist and his beekeeping neighbor. Very often the neighbor will become alarmed as soon as he sees the spray-machine at work, and in some cases he will claim that every dead bee that he finds for weeks to come was killed by the arsenic spray.

A NEW SPRAYING SOLUTION THAT IS REPELLENT TO INSECTS

During the last two seasons a new spray material has come into very general use over the country. This is the dilute lime and sulphur solution as a substitute for the old Bordeaux mixture. The Bordeaux was simply a mixture of copper sulphate and lime, and it was used in connection with the arsenate of lead or with Paris green. The new sulphur spray requires the addition of the arsenic, just as the Bordeaux did; but it possesses the added advantage to the beekeeper that it is repellent to all insects. The smell of the sulphur is so strong that trees sprayed with it are notably free from insects of all sorts during the period through which the smell lasts. In this way the bees are repelled along with certain injurious insects (notably the plum curculio). This repellent action of the lime and sulphur will no doubt go a long way toward easing the fear of the beekeeper. For my own part I feel so sure of the repellent value of the sulphur that I will venture the assertion that no harm would result to the bees, even if the orchard should be sprayed while in full

bloom. Of course it would be highly undesirable to spray the trees when they are in full bloom; but I simply make the statement to show my confidence in the repellent value of the solution.

I should be very glad to hear the last of the controversy concerning the killing of bees by spraying; but I know that there will always be beekeepers who will not read, and fruitgrowers of the same class; and, further, that there will always be the individual who is ready to pick a fight with his neighbor. I have no doubt that the spray-machine will continue to be a sore point with beekeepers for many years, just as the stinging, stealing, and "eating" of fruit by his neighbor's bees will continue to be a thorn in the side of the unreading orchardist.

In conclusion I will say that the Greenhorn bought some bees, thereby improving his chances of success, and, incidentally, opening the way to much ultimate pleasure, although we will admit that beekeeping for the beginner is not an unmixed joy.

Indianapolis, Ind.

THE RECENT NEW YORK STATE CONVENTION

Raising Cells without Queen Cups or Grafting; a Simple and Practical Plan for a Honey Producer

BY R. F. HOLTERMANN

Many years have passed since I attended my first convention of beekeepers in New York. I am told it was thirty years ago at Rochester. Many beekeepers I have known have since then fallen by the way to remind us, too, of eternity.

The convention which has just closed at Syracuse, and at which the writer was present (for the New York State Department of Agriculture was largely attended), there appeared to be dozens of men who were operating from 400 to (if I am not mistaken) over a thousand colonies of bees, and I heard of more like them in the State. These beekeepers impress one; they know their business; they are not content with going in well-known and beaten paths, but they are on the outlook for improved methods, be they original with themselves or not. They have an understanding that, to combat ideas, is not to be antagonistic to individuals. The fire may fly in mental combat, but no friendships are disturbed by such conflict. Notably among that class is W. F. Marks and Geo. B. Howe, the latter one of the State inspectors.

Of the many good things brought out at the convention, that which impressed me most was the production of queen cells by a method which does away with the necessity of larvæ transfer or the making of queen-cell cups. In a private conversation the writer had been informed of this process by D. R. Hardy, Burrs Mills, N. Y. It appears that no one present claimed to be the originators of this method; but the New York beekeepers appear among themselves to

have given out the idea on the quiet, and Mr. Hardy, in the kindness of his heart, and out of pity for the uninitiated, had given me the wink.

The plan was made public when Mr. Oscar Dines, of Syracuse, took the floor on the morning of Feb. 1, following Mr. West on the subject, "Some Things I have Seen," and he made us sit up and listen when this method of queen-cell production was described. Mr. Dines stated that he took a suitable comb (or two combs) and inserted it in the center of the brood chamber of the stock containing the queen from which he desired to breed. After the queen had laid in this comb, and the larvæ were ready, the comb was cut to the midrib along the topbar. Then a similar cut was made between the second and third row of cells from the topbar; another cutting between the third and fourth row; another between the sixth and seventh; another between the seventh and eighth row, and so on. The two rows of cells are destroyed to the septum, leaving rows one cell wide with a two-cell-wide space between, over the entire one side of the comb. A phosphorus match is now taken, and in the remaining rows one cell is left intact, and the larvæ in the next two destroyed, and so on throughout the comb. This prevents the joining of queen cells by the bees.

I should have mentioned that, before the comb is cut to the septum, it should be shaved down so as to leave only a shallow cell as in the Alley system.

The comb is now mounted in a rim $2\frac{1}{2}$ inches deep, and as wide and long as the hive. This rim is then placed upon a hive with the comb lying horizontally over the brood nest. The comb is so suspended that the upper side of it is level with the top of the rim, leaving ample room underneath the cut-down comb wall and the topbars of the brood frames for the development of queen cells.

Mr. Dines stated that he had secured 65 fine queen cells by this method at one time by placing the prepared combs and rim on a queenless colony. Mr. Case, of New York (I regret I did not get his initials), stated that, by taking such a comb and giving it to a strong queenless colony three days after taking away all its brood, so that the colony had no other brood or larvæ to care for, he had secured 105 fine cells. The septum of the comb became the foundation for the queen cell. It was thus readily handled. The upper side of the comb should be covered over by pasteboard to prevent the bees from paying attention to the larvæ in the cells. When the cells started are ready, a beekeeper who wants to requeen need only go to the colonies he desires to requeen, remove the old queen, and insert between the frames one of the queen cells inserted in a West cell-protector, and the colony will secure a virgin queen when hatched.

LARGE BROOD CHAMBERS.

Many New York beekeepers are in favor of ample brood-chamber capacity. One of

them, I do not remember who, stated that Mr. McIntyre, the well-known Californian beekeeper, made it a point to buy queens from queen-breeders who use large hives, as he held that queens in such hives are likely to be more prolific, and are likely to throw progeny with better laying powers.

Brantford, Ont.

[The plan here described is similar to the Alley method that was given some 25 or 30 years ago. The principal difference is in the manner of giving the prepared comb to the bees. Alley hung the comb in the regular way in the hive; but in the plan here described, it is suspended *horizontally* above the brood nest.

If we are correct, Dr. E. F. Phillips, of the Bureau of Entomology, gave this plan to the York State beekeepers some two or three years ago. Whether he or they originated the idea of placing the comb horizontally above the bees, we can not say. In any event, the plan has the merit of avoiding the use of queen cups and of grafting; and in the hands of the average beekeeper it would probably give better results than the grafting plan with queen cups.

A caution should be entered against trying to get too many cells at one time from a colony. We have raised a good many thousands of queens; but our experience teaches us that the average colony will not take care of and feed *well* more than two dozen cells. They will build as many as a hundred; but queens from such cells are apt to be short-lived or poor layers.

This method was described by Mr. Friedman Greiner on page 170, 1911; but the very fact that it is giving such general satisfaction to our friends in New York would indicate that another description, as given above, will not come amiss.—Ed.]

HONEY-CROP REPORTS

BY WESLEY FOSTER

While attending the National Board meeting, some one (I think it was Mr. Pettit) asked me why Western beekeepers held back their report on crop conditions. I answered in an offhand way that it was, no doubt, because they hoped to get a better price by so doing. I have been looking over the honey reports that were sent in, and I do not find many that are very misleading. I am surprised that my report in the September 1st GLEANINGS, 1911, came as near being right as it did, for it was sent in before August 15. It is not possible to tell accurately about the alfalfa crop in this latitude until after August 1. Often the bees will do nothing, scarcely filling their hives and doing no swarming; then the second growth of alfalfa comes in bloom about August 1, or perhaps a little earlier, and a fair surplus is made in August and September. I should not want to give a report on the honey crop until the middle of August; and then if the weather remains hot, and the alfalfa is yielding well, the crop may be doubled in the last ten days of August.

In GLEANINGS for September 1 a good report was given of the California crop, although the crop was not as good as was expected. Was the trouble that the beekeepers did not offer their crop for sale? I reported that the Colorado crop was larger than for some years, and I now think that was a little strong, although we still have a good deal of alfalfa honey (extracted) to dispose of. Without doubt more extracted honey was produced than the market could handle, and altogether too little comb honey for the demand. Again, in GLEANINGS for October 15 a bountiful crop is reported from California. Was not part of the trouble because the producers did not offer their honey for sale soon enough? Idaho had a light crop in the west-central part, while in the Twin Falls and Idaho Falls districts it was good. The crop seems to have been good in Utah and Wyoming.

The production of honey is increasing rapidly in the West, and new districts become of shipping importance almost every year. Many of these beemen are new, and do not look for a market until the honey is all harvested. A study of conditions in marketing should be made before rushing extensively into beekeeping. There are, undoubtedly, many inter-mountain regions which would produce a fine white article of comb honey, and there would be more money in comb honey than in extracted with market conditions as they are at present.

I think that Easterners are, perhaps, as much to blame for market conditions right now as are the Western producers. In the East, on account of the poor crop they put the price up; and just as they got things started at high prices then Western honey began to come east and knocked the bottom out of the market.

In regard to Western market reports as a whole, nothing definite can be given before September or October. Many of the producers do not finish extracting until November, and it is hard to judge of the amount the supers will yield. Then we never think of offering much of our honey, especially the extracted, before the harvesting is pretty well out of the way. In case of comb honey some of us have learned to get it off as soon as possible, and often that is not early enough for the best price.

As an example I figured that one apiary would run close to 100 pounds of extracted honey, per colony, spring count. I estimated so much for each super on the hives. We did not finish extracting until November, and found it was only about a 70-lb. crop. We shall have to figure on our crop reports not being in until later, if we want to know the conditions more definitely.

There is nothing more necessary for the stability of the honey market than accurate reports, and a central head to direct the distribution of the carload shipments of honey. The West is big, and its product so large that something will have to be done to hold things steady. This is a need that the new National Association can supply.

Boulder, Col.

IS THE LANGSTROTH FRAME TOO SMALL?

The Size or Shape of Frames Not a Factor in Wintering

BY F. P. CLARE.

As Mr. Simmins' article in the January issue of the *Canadian Bee Journal* may be confusing to beginners, and as Mr. S. invites criticism, I write to draw attention to what appears to me some of the errors in the ideas he advances. He asserts positively that the Langstroth frame is *too shallow for successful wintering, indoors or out, and too small for the honey season in any locality*, and then, in the next breath, urges beekeepers to use a frame of less than three inches greater capacity. Laughable, is it not? Is it, Mr. Editor, a matter of "location making the difference"? Scores of us have proved here in Ontario that successful wintering is secured, *every time*, by the quantity and quality of winter stores, and not by the *size or shape of the frame*.

With an experience of over 30 years, with (at one time) 260 colonies of bees in 15, 12, 10, and 8 inch depth hives, I assert positively that, with an abundance of good stores, in a proper repository, bees will winter as successfully on the Langstroth frame as upon any frame with which I am acquainted.

If I were starting in the business again I would use no other, and ten of them in a hive. The points of superiority are many. Ten-inch lumber for the construction of hives can be procured quite readily, which is not as true of a deeper hive. When it comes to securing the harvest, by tiering up as well as placing in winter quarters, where do you find its superior?

The larger the hive, the greater the quantity of bees produced, and the larger the amount of honey stored, is Mr. Simmins' reasoning. Possibly this may be true of some locations, but it certainly is not true of this part of Ontario. A queen that will keep eight Langstroth frames full of brood will have to lay over 2500 eggs daily for weeks at a time. Where can queens be found that will average better than this? Allowing two frames for honey and bee-bread, we have ten frames which experience has proved are ample for an average queen in most seasons and locations.

Now, if this capacity is doubled, what will be the result? Beebread and brood through both stories, if two stories are used and honey stored in the brood nest that should have gone into the super above the queen excluder. In addition to this, honey will be used by the bees, if not pure Italians, to raise thousands of bees that are too late in coming upon the stage of action to be of any value in securing the crop of white honey. While great numbers of bees are all-important at the right time, out of season they are a detriment.

Mr. Simmins blames the eight and ten frame Langstroth hives for the average crop reported by Mr. Root. Does not Mr. Simmins know that atmospheric conditions,

over which the beekeeper has no control, generally determine the amount of honey stored? Who has not been disappointed in returns when bees were booming at the beginning of the harvest? Is the size of hive to blame for this? Thousands of colonies of bees are still kept in box hives and "gums" in mountainous regions and through the Southern States, and all these pull down the general average; but no intelligent beekeeper considers Mr. R.'s figures as the average of his apiary.

In conclusion, Mr. S., permit me to inform you that a crop of from 200 to 400 pounds of extracted honey has actually been produced by users of the despised Langstroth frame, and by those who have kept their bees in eight and ten frame Langstroth hives.

And now, Mr. S., I want you to take your pencil and figure out the bees that would be in a hive that contains the "equivalent of two 16x10-inch eleven-frame chambers crammed solid with brood."

Allowing $8\frac{1}{2} \times 15\frac{1}{2}$ inches of brood comb to each frame, there are about 2882 inches of brood. Allowing 50 bees to the square inch, the result is 144,100 bees. Now allow as many more bees in the hive to care for the brood and to gather honey, and there will be 288,200 bees or about 60 lbs. of bees. Such a colony should store 600 pounds easily, and the mother of that stock—is she for sale? and what will you take for her? Kindly address at once, and mark the letter *rush*.

Toronto, Canada.

[If Mr. Simmins were more familiar with the diverse conditions in this country, with all shades of climate and temperature, he would not make the statement that a 10x16 frame would enable us to do better wintering than now or to secure more honey. The Jumbo hive, with frames slightly larger, have been sold for years; but there is comparatively little demand for them. More and more the tendency seems to be to get back to the original Langstroth frame. From 1885 to 1890 there was a rage for shallow frames. During the latter part of the '90's there seemed to be a tendency toward the Quinby or Jumbo frame; but years of experience seemed to lead back to father Langstroth. During the early '80's the whole beekeeping world swung from the ten-frame Langstroth to the eight-frame; and now we are swinging back from the eight to the ten. There was formerly a belief that a deep frame would winter bees better than the Langstroth; but when these frames were tested side by side, year in and year out, the Langstroth always seemed to hold its own. It is indeed remarkable that father Langstroth was so nearly right in so many things. While this winter may prove to be a severe one on bees, the size or shape of the frame will have nothing to do with it.—Ed.]

Heads of Grain from Different Fields

Artificial Pasturage for Bees; Plants that Can be Grown Profitably

What is the best known plant that can be raised for bee pasture? I am thinking of sowing one or two acres of mignonette. Do you think that bees will stop on that, and neglect gathering honey from basswood or white clover one-half to three miles distant?

Oakfield, Wis., Feb. 22.

F. W. WELLS.

[As a general rule we may say that it is not advisable to grow any plants for the honey alone. If, therefore, you wish to put out artificial pastures for the bees, grow some plant that will yield seed or hay in addition to the honey. For this purpose we know of nothing better than nor quite the equal of alsike clover that is now being grown so extensively all over the United States. Next in order we would place buckwheat, red clover, sweet clover, and (in the Western States) alfalfa. Basswood is, of course, one of the greatest honey plants or trees in the world; but it takes so many years before it begins to yield nectar and lumber that the one who puts it out must have an idea for future generations.]

Ordinary white clover is, of course, a splendid honey plant, and it yields a good forage for pasture. It is also being grown to a considerable extent. Red clover and peavine red clover yield considerable nectar; but the corolla tubes are so long that the average bee can not get very much honey from them. If, therefore, you desire to produce honey and hay you had better, by all means, grow alsike, sweet clover, or white clover, rather than either of the red clovers mentioned.

Sweet clover is one of the most valuable honey plants we know of, and, when cut early enough, it yields valuable hay for stock. In many sections of the country sweet clover is being put in to prepare the soil for other clovers; and on some waste lands where no other clover will thrive it will make fine pasturage for stock.

Mignonette is a wonderful honey plant, but that is about all that can be said of it. There is only a limited demand for the seed. There would not be enough of it grown to pull the bees off from clover, if it were within three miles.

Perhaps it would be well to explain that, in order to get any considerable amount of honey from artificial pasturage, we have to figure on anywhere from five to ten acres of pasturage to a colony of bees. In some cases, and particularly some seasons, a much less acreage would be necessary.—Ed.]

Beehunting Pays

In reply to P. C. Chadwick, p. 39, I beg to say that any one would certainly know better than to save a swarm of bees from a tree if they are affected with foul brood. Right here the same law should apply, and should impose a fine of \$5.00 and costs for cutting a tree infected with foul brood, and saving either bees or honey, and also for failure or neglect to destroy effectually the entire contents of such a tree by burning, so that other bees near it may have no chance to convey any of the honey therefrom, and thus spread the disease. As to whether beehunting pays in a financial way or not is wholly at the option of the operator. Would it pay to buy bees in the spring, and kill them in the fall to get their honey? Does it pay to cut down the apple tree to get the apples? Does it pay to cut the hickory tree to get the nuts? Does it pay to kill the sheep to get the wool? In fact, does it pay to kill the goose that lays the golden egg? All bosh! I have made no misstatement. It pays *me* to hunt bees, and under the same management it would pay Mr. Chadwick or any one else. I should like to live in a country where I could find nine beetrees while walking a distance of two miles. I would soon have the bees in hives, or destroyed if diseased.

Union Center, Wis.

ELIAS FOX.

Bees Poisoned by Careless Spraying at an Experiment Station

Some time ago I wrote you that my bees were killed as a result of our experiment station spraying apple trees while in bloom. They deny that

the apple bloom was in condition to poison the bees. It is true that the early apple bloom had fallen; but Rome Beauty was in full bloom, and the bees were working busily on the blossoms. My bees were very strong at that time. They died by the thousand, the ground near the hives and close to the alighting-board being covered with dead bees. There was a great increase in the number of dead bees at the time of spraying, as the colonies were then very strong.

The bees did not starve to death, for some of the hives contained 25 pounds of honey at the time the bees died. Others had more than that amount.

The bees that did not die at once lingered in a weak condition. Moths fixed many; and others went into winter quarters with enough old honey for wintering, but not enough bees to cluster and keep warm. I do not understand why the bees that were weakened by the poison did not build up strong during the season. Many died in a few weeks after the spraying.

Of 48 colonies but 12 are living. I think that three-fourths of all the bees in Pleasant Co. and in Wood Co. went the same route because of careless spraying.

Salama, W. Va.

MARTIN WILKINSON.

Queen-rearing in Florida or Texas

I am interested in the queen-rearing business, and would like to know of a place where I can rear early queens. How would the west coast of Florida or Southwestern Texas do for that business? Do you know of a better place than either of these? Can you suggest a definite location in either of the above or any other section of the country?

Bradford, Ky.

M. A. AULICK.

[The west coast of Florida would be a very good place to rear queens if you could get away from the water and rivers where there are mosquito hawks. One great difficulty in rearing queens in Florida is these hawks, and the large red ants that have nests in trees. The mosquito hawks will sometimes paralyze queen-rearing operations in a few days, while the red ants will destroy whole colonies. There is no remedy for the mosquito hawks except to get into a locality where they have never been known to come in droves. You would have to get well away from water. In doing that you would get into desert country, probably where there would be no flora for bees. The nuisance of red ants can be overcome to some extent by placing the hives on leveled-off ground where there is no vegetation nor rubbish. Hives must be put up on stilts or framework. Grass or rubbish of any sort must be kept entirely away from the apiary for a distance of 25 or 30 feet. Do not leave boards of any kind on the ground. The apiary should be in the open, away from any trees.]

Southwestern Texas might and probably would present better conditions for queen-rearing than any place in Florida.—Ed.]

Paper Protection Not Sufficient in Cold Climates

Mr. Miller's paper protection, p. 73, Feb. 1, may be sufficient to carry bees through winter in Rhode Island; but my experience here in Central Wisconsin has proved it to be a failure in severe winters. To satisfy myself as to the merits of the black paper as a winter protection, I prepared two colonies in the fall of 1910 by placing a super on top, filled with planer shavings; then the cover, and then over and around the hive and super, not common tarred paper, but a heavy tarred felt. One of the colonies so prepared was strong in bees, the other having a less quantity. The entrances were $\frac{3}{4}$ in. deep by 7 in. long. The result was as follows: The stronger colony pulled through in a weak condition with a heavy loss of bees. The other pulled through the cold weather; but before the first of April there was not a live bee in the hive. During the same winter I had 15 colonies in my cellar, a part of which were light, both in stores and bees; but all wintered well. During the past few seasons I have adopted the Alexander plan of wrapping my hives with felt on removing them from the cellar; and this with me has proved to be very valuable. While I do not wish in any way to criticize Mr. Miller, yet I feel that I ought to sound a warning to the inexperienced beekeeper not to attempt

to winter bees outdoors in a climate where the mercury goes down from 30 to 40° below zero unless they are packed in chaff or double-walled hives.

Elroy, Wis., Feb. 9.

CHAS. SHELDON.

Great Demand for Bees in Orchards

Notwithstanding the extremely cold weather, bees have wintered much better than I expected. I have lost only a few. I have some fine colonies in strong condition which wintered outdoors in ten-frame single-walled hives. There is a wonderful demand for bees for fertilizing orchards in this State, and I am sorry to say that bees are decreasing greatly. In consideration of the fact that the planting of orchards is going forward in remarkable leaps and bounds, the demand for bees will increase considerably.

Notwithstanding the loss of bees by the unusually severe winter, the remarkably poor honey seasons of the past two years, and the terrible encroachment of bee diseases in this State, I am very optimistic; and personally I am satisfied that with beekeeping, as with all other industries, the time to go into it is when all other people are going out. The future for this special branch in this State looks very good and promising to me.

Economic Zoologist.

Harrisburg, Pa.

The Cover Picture for Feb. 15

I can't tell you how surprised I was this morning to find on the cover of GLEANINGS for Feb. 15th the picture of our beeyard at our old home in Evart, Mich. The photograph was taken by W. Z. Hutchinson while on a visit to us about sixteen years ago, and we still have the original copy. While I was recovering from my surprise at seeing the picture in a place where we had no reason to look for it, I was thrown into fresh wonder as to how your father's Florida ducks and drakes got into our old trout stream; but in these days of moving pictures I suppose we are not to be surprised at any thing.

The man in the picture is Mr. Walker, and the buildings shown were our barn and shed, the house not appearing. The stream was a beautiful creek called Twin Creek, and many were the beautiful speckled trout the boys from our neighborhood pulled out of it. The scene is just off the banks of the Muskegon River. If the picture looks half as good to your readers as to our family they are, no doubt, charmed with this specimen of Mr. Hutchinson's photographic skill.

MRS. BYRON WALKER.

Honey Reports from California Not Misleading; a Crop of 38 Tons

I wish to enter a protest against what you say on page 35, Jan. 15, in regard to the honey reports from the West, when you make the statement that many of the reports were misleading, and that some producers were holding back the facts. The truth is, for Central California, that we did not expect a good crop early nor even in the middle of the season. I thought when you published Madary's report that it was about right. Here in the valley the bees commence to gather surplus from alfalfa about June 1. We begin to extract honey July 1, and get through Oct. 1. Last season we got the bulk of the honey during the last half of the season. Beekeepers tell me that this is true of the location west of us in the mountains. They have the sage first, then wild buckwheat, and last season we had a late heavy flow from blue curl.

I did not see any reports from Central California that looked misleading to me at the time they were published. Of course, when you say "the West," that is a big country, and you may have some excuse for talking so.

My crop was 38 tons. Early in the season I did not expect 24; but we are having a hard fight against both American and European foul brood.

Hanford, Cal.

P. H. BALES.

Recipe for Making Honey Vinegar

You say that anybody who can make cider vinegar can make honey vinegar. Nine out of ten, however, make the sweet vinegar sour, as nearly all use too much honey. In this case the microbes have died. I will here give a formula which will

make good vinegar. If the wash water from cappings is used, or dirty honey from trees, etc., a hydrometer must be used. This hydrometer must register 30 in the sweet water; and if clean honey is used in the proportion of 7 lbs. of honey to 5 gallons of water it should register 30. Here is the formula: Honey, 7 lbs.; water, 5 gallons; potassium bicarbonate, $\frac{1}{2}$ ounce; sodium phosphate, $\frac{1}{2}$ ounce; ammonium chloride, $\frac{1}{2}$ ounce; a piece of yeast the size of a pea. The chemicals are used for the purpose of causing fermentation.

After a few days this makes a fine drink like sweet cider. When it has ceased to ferment, strain and put into a clean keg and add one quart of vinegar and some mother.

Big Wells, Texas.

Bees and Grapes

Can you give me any information in regard to some productive plant to sow for my bees—something that, with favorable weather conditions, will be in full flow about the time grapes are ripe? I had thought of Japanese buckwheat. If you would advise me to sow that, when should I do so, and how? How much would be required to sow half an acre? Where can I obtain it? I wrote you last summer, saying my neighbor complained that the bees were destroying his grapes. My object is to sow something on my place that will be yielding about the time grapes are ripe, and see if that will help matters.

Kewanee, Ill.

E. R. WILKINSON.

[We do not know of any thing you could set out that would be in bloom about the time that grapes begin to ripen—or, rather, at the time when the bees are liable to be bothersome. If you will investigate the matter thoroughly you will find that bees do not spoil nor injure in any way the sound fruit. See what Professor Surface and other writers have to say in this issue. If you could hand your copy of this number to your neighbor we believe he will be convinced that the bees were simply sucking the juice from grapes that were already spoiled.—ED.]

The Larger Part of Alfalfa Cut Before it Blooms

I have been interested in the different theories given concerning alfalfa bloom not giving as much bloom as formerly, and the practical reason has been overlooked. By far the larger part of the crop is cut before it blooms. The sheep-feeders here, in the best alfalfa section of the Arkansas Valley (western part of Bent Co.) cut the first crop just as soon as it begins to bloom, and the three other crops before blooming. All that is left is a small portion for seed. It is like Wateley's reason for white sheep eating more than black—because there are more of them." So, conversely, the reason bees don't gather as much honey as formerly from alfalfa is, the alfalfa is cut before it blooms.

Of course, this sounds like treason to men with several hundred stands of bees to unload, and who use the real-estate-boomer slogan, "Be a booster and skin your sucker." I think men should be truthful in their statements concerning bee territory. Any one interested can come and see during July, August, and September, when hay is being cut. It will be seen that the first crop, cut in June, is the only one given any chance to bloom.

Las Animas, Col.

L. H. SWEETMAN.

The Gravenstein Apple

I can tell Mr. Root a little about the Gravenstein apple. I was born and raised close to the little village of Gravenstein. In the old garden belonging to the old-time castle stood the old apple tree from which all Gravenstein apple trees originated. It is surely the best apple that grows; but the tree is not hardy enough to grow in all climates and under all conditions. On the Pacific coast, in Washington and Oregon, is a climate like its native one, and there it grows to perfection.

Brush, Col.

DANIEL DANIELSON.

Bees Pleasant to Handle.

I am glad to say that the bees of this country are not like those described by Mrs. Henry A. Gooch, p. 766, Dec. 15, but are very pleasing creatures for a woman to work with.

ANNA SOMMER.

CHICKEN THIEVES; WHAT SHALL WE DO TO
PROTECT OUR VALUABLE STOCK FROM
THEIR DEPREDACTIONS?

In our issue for Feb. 15, p. 106, I spoke of losing a duck and a drake. Well, about the middle of January two more were gone when the flock came home at night; and finally on Sunday evening when they got home my only remaining drake was gone. It was not so much the loss of the five ducks as it was the fact that I must stop letting my ducks run at large in the drainage canal that adjoins my five acres. After losing the two we went to considerable expense and trouble in making a fence in the rocky bottom of the stream so as to give them a place to swim in close to the shore; but as this prevented them largely from getting the moss and shellfish, the yield of eggs soon dropped off. Last, and by no means least, I was forced to conclude some one was taking lessons in theft—regular progressive lessons—and getting off “scot free” every time. Something *had* to be done. I hardly need tell you I prayed over the matter again and again. The outcome as to what was best to be done was the following, which I clip from the Bradentown *Weekly Journal*:

“THOU SHALT NOT STEAL.”

Ed. Journal:—I have repeatedly, both in print and by correspondence, extolled Bradentown and vicinity as remarkably free from petty thieving, and remarked that, after being north all summer, we invariably find every thing about our premises intact on our return. Well, I greatly regret to be obliged to report we have at least a few sinners as well as saints in our midst. Five choice breeding ducks (with excellent records) have been taken from our flock recently. All were taken in midday—the first, the day before Thanksgiving; the second, the day before New Year’s day; two more in January, and the last, a large choice drake, the only one I had left, was taken yesterday, February 11 (probably while we were at church and Sunday-school); and to get him the culprit broke through a fence of barbed wire and poultry netting, drove him into a corner, and evidently killed him with stones taken out of the brook they waded through to get to the fence. Although the loss of this drake just now blocks my work with the incubator, and is a great inconvenience to me, this is nothing compared to letting some one (possibly a boy or boys) go on unhindered in the school of crime. Does it not behoove every industrious, law-abiding citizen to call a halt at such work in open daylight, and mostly, if not all, on Sunday? Such work may call a halt in developing an industry that this region seems particularly adapted to. A. I. Root.

The second clipping from the same journal, a week later, gives the result, as you see:

AN INTERRUPTED PILLAU.

The parties who have been making raids on Mr. A. I. Root’s ducks, as published in last week’s *Journal*, have been captured, and the ringleader, a young white man about 18 or 20 years old, is now in jail. Sheriff Wyatt walked up on them last Sunday as they were gathered around a fire out in the woods cooking a Pillau. Out of regard for the parents of the boys we withhold names, but we hope these parents will not withhold the lash.

The arrest of the gang of five boys was owing to the kind service of Dr. Morgan, a near neighbor and a longtime subscriber to GLEANINGS. He had but two ducks, and

at first decided to pen them up while at church on Sunday, but afterward concluded to leave them out in the canal and stay at home from church and watch. About 10 A.M. the ducks were missing. He followed along up the stream, and on coming to a piece of woods he saw smoke arising. Further along he found the feathers, and then came upon five boys with a kettle, cooking their duck. Without alarming them he proceeded to the nearest house, and called up by telephone the sheriff. Now, here is something I want you all to make note of. When the oldest one, and evidently the ringleader, was arrested he had a *cigarette* in his mouth, and kept right on smoking it, proclaiming that *he* “just happened” along, and was in no wise connected with the other youngsters; but (if I am correct) he was the one who announced, when the sheriff proceeded to confiscate the kettle (duck and all), “Here! that is my kettle.”

Now, friends, would it be a very long jump, in “jumping at conclusions,” to say it was *cigarettes* that stole my five ducks?

In that excellent book I have just referred to, the Corning Egg Farm, there is a chapter that is headed, “Policing the farm with bloodhounds, searchlights, and rifles;” and the chapter starts out with these words: “In the fall of each year, from almost every part of the country, come reports of what seems to be organized thieving in the poultry line,” and then the author tells about what they are doing with bloodhounds, searchlights, and sharpshooters. I need hardly tell you that these cigarette saloon-frequenters would just as soon take your most valuable fowl for a roast in the woods as any other, for there are veritable *heathen* right here in our land of schools and churches. Let me advise, in closing, the need of a law-and-order club among poultrymen, with dogs and detectives, to punish such offenders until they have had enough of it. Let a fund of money be raised that will be ample to meet the expense of getting the culprits, swift and sure. Since this matter came up, my neighbors, right and left, tell of having had valuable fowls stolen. Let me here repeat a little story I told you some years ago. When I was witnessing the early experiments of the Wright Bros. I boarded with a farmer whose wife was on a decline with the great white plague. To prolong the life of the poor woman (and they were poor financially) the doctors advised poultry-keeping in order to have her in the open air as much as possible. She became quite enthusiastic, succeeded with the poultry, and was improving in health, when one morning as she went out to liberate her pets that she had labored so hard for, to get them up to broiler age, she found every chick gone, and just the still empty coops. The shock and disappointment were so great she went into a decline, and not

long after went down to her death. A neighbor, who had been having similar losses, got up in the night and attempted to stop some thieves who were just making off with a load of his chickens, and the thieves turned a gun on him and ordered him to go back. He aroused his neighbors, and they followed them until they were lost with their booty in the saloon haunts of the great city of Dayton, Ohio, with its hundreds of saloons running day and night. How long, O Lord, shall this devastating curse afflict and discourage our hard-working and law-abiding citizens?

A BALANCED RATION; LETTUCE FOR DUCKS;
MORE "DISCOVERIES," ETC.

Somebody said Prof. Holden had put corn on the witness stand, and made corn answer his questions. Well, I have been putting ducks and chickens on the witness stand, and I am going to tell you what answers they have given me. By the way, what a *big lot* of valuable "discoveries" I am making lately! Just think of it! yesterday I got 79 eggs from only 75 laying hens. Mrs. Root declares, however, that I should explain to you all that I gathered the eggs so late the day before that several laid after they were gathered; and this reminds me that our hens have got on such a craze to lay lately that they commence, some of them, at sunrise, and some of them are on the nests laying at sunset. How did I succeed in getting up such a "laying contest"? That is just the wonderful discovery I am going to explain to you.

When I was down on the island several years ago I told you about my flock of chickens that were all the time teasing for something and were never satisfied until I discovered they were hungry for animal food; and when I gave them a good "square meal" of fresh fish they all went and sat down in a row on a log, happy, contented, and *satisfied*. That was a lesson I have not forgotten, and I try to feed my ducks and chicks so that they will "go off and sit down," quiet and happy. Whenever they fail to do this, especially young growing stock, you may be sure they are *lacking* something. When my first brood of ducks from the incubator were about a month old they were always teasing uproariously for something. Their first feed was bread and milk, and I supposed they were begging for their milk ration that had been dropped, because milk costs so much down here. The only feed they would eat was a mash of bran and middlings; but they wanted it all the time, and I soon noticed their droppings looked very much as if the coarse bran was imperfectly digested, and began to wonder if the fine Florida sand I had been depending on for grit, was sufficient. I gave them some of the mica crystal grit that we always keep before the chickens, and there was an improvement. Seeing oyster shells advised by one of the poultry journals, for *ducks*, I tried them; and every pen of ducks, from the oldest to the youngest, took to them

greedily. One pen of four-weeks-old ducks ate such a quantity I feared to let them have *all* they wanted; but not until our neighbor Rood began shipping lettuce did we discover the "long-felt want." They at once dropped their grain and every thing else for the coveted lettuce, when they fairly got a taste of it. Well, my *discovery* that we have been so long getting at is this: Lettuce is not only *good* for ducks, but it takes the place, largely, of the expensive grains, shorts, and middlings. Just as soon as they had lettuce, all they could consume (and it takes about a wheelbarrowful a day for twenty six-weeks-old ducks) the amount of grain needed dropped off amazingly, and the whole lot of ducks would go off and sit in a row, and stay there for hours—a thing they had hardly done before since the day they were hatched. Of course, I knew ducks as well as chickens need green food as well as meat and grain; but as each of the three pens had quite a range, with Bermuda grass and other green stuff, it did not occur to me they were suffering for so large a quantity. They kept teasing for their mash, no matter how often I fed them, but they did not seem satisfied; but now they are growing at a rate that surprises everybody who passes along the highway. Have you not heard of babies that kept crying for something they scarcely seemed to know what it was themselves? Well, is it not possible that, like the ducks, something was lacking in order to let the little darlings make flesh and blood and bones, as nature intended? It may not pay to grow lettuce for ducks and chickens alone—that is, when they are full grown; but it certainly will pay, and pay well, to give small ducks and chicks all they can consume; and down here, where lettuce is grown by the acre, there is always more or less unfit to ship; and during this past very wet season there has been an unusual amount that is just the thing for fowls, but too far in maturity to think of sending to the Northern markets, so you see this is just the place for the "duck man." The large quantity of nice head lettuce given the laying hens is probably what has caused the "laying contest."^{*} For a whole week, ending March 1, 75 hens have averaged about 60 eggs a day, but the price is down now to 20 cts. a dozen here.

The Russian government and the zemstvo organizations of that country are paying great attention to the development of beekeeping. Schools of apiculture are maintained, and staffs of apicultural instructors are sent to various points as needed. Peasants beginning beekeeping are given one or two proper hives free. In some cases hives are sold at low prices on the installment plan. Apiculture is a favorite occupation of small landowners and the working classes. —*Florida Times Union*.

*Just recently I have also given them a 10-cent box of ground mustard, a teaspoonful daily, in their daily mash.

DISCRIMINATING AGAINST OUR OWN PEOPLE

I clip the following from the *Ohio Farmer* for March 2:

WANTED—A REAL PARCELS POST

As you know, reader, from previous articles that have appeared in *The Ohio Farmer*, in carrying packages by mail, our government actually discriminates against its own people, in favor of other nations. Our postoffice department at Washington has "conventions," or agreements, with 29 other nations, by which it carries packages weighing up to 11 pounds from any postoffice in this country to any postoffice in those countries, for 12 cents per pound. For 12 cents per pound you can mail from your postoffice packages weighing up to 11 pounds, to London, Berlin, Vienna, Stockholm, Rio Janeiro, Valparaiso, Jerusalem, Melbourne, Tokio, Peking, Mukden, and to more than 10,000 other foreign postoffices scattered over the globe. But a package mailed to the next town, in the United States, must not exceed 4 pounds in weight, and the carrying charge is 16 cents for each pound.

And as though those discriminations were not enough, our postmaster-general has made arrangement with British postoffice authorities recently, whereby mail packages up to 11 pounds are carried from any postoffice in England, Scotland, Ireland, or Wales, to any postoffice in the United States, for the following charge: Up to 3 lbs., 30 cents; up to 7 lbs., 55 cents; up to 11 lbs., 79 cents. By this agreement a British subject can send 11 pounds in one package from his postoffice to your postoffice for 79 cents; while you wishing to mail matter weighing 11 pounds to your nearest postoffice in this country, must break it up into three packages of not over 4 pounds each, and pay \$1.76 postage—a discrimination of 100 per cent against you.

As allowed by law, the postmaster-general is steadily extending these special postal privileges to foreign nations. This is right, and best for all concerned. On the other hand, the only change congress has made in carrying parcels for our own people, during the last fifty years, was in 1875 when it raised the postage on parcels from 8 to 16 cents per pound—double the cost.

Well, after you have read the above twice over (or *more*) read this, from another part of the same issue.

EXPRESS CO. INVESTIGATION

The Interstate Commerce Commission has found in its investigation of the express companies that they have made charges above their published rates, and now hold in their treasuries \$81,957,893, a large proportion of which is excessive charges wrongfully obtained. Criminal proceedings have been ordered and an indictment has been returned against the Adams Co. The following are the companies and the amount in each treasury: American, \$39,635,603; Adams, \$24,133,486; United States, \$10,737,518; Wells-Fargo, \$7,936,377; Southern, \$3,902,853; Northern, \$999,551; Globe, \$386,856; Western, \$82,787; National, \$2350.

Where is the man or woman who has not contributed (under protest), more or less, to this fund of over *eighty millions*? And how long is our postal department going to continue to carry and deliver stuff for foreign nations at a lower price than she does to our own people? What is the matter of *us*? How about "By the people, for the people, and of the people"?

PUTNAM CO., FLA., AND ITS ARTESIAN WELLS.

GLEANINGS IN BEE CULTURE says that in Putnam County, Florida, "they do not have artesian wells," italicizing the "not." Has friend Root, who says that he owns land in that county, never observed the six-inch pipe at the back of the Putnam House, in Palatka, conveying the water from a flowing well at its base to the third story? The pressure on that pipe is so great that the writer remembers one day when the pipe gave way and all the gutters of the little city ran deep in sulphur water for days, blackening all the white-lead paint on the houses and the silver doorplates as well.

That is only one of the numerous wells, some flowing, in Putnam County.—*Jacksonville Times Union*.

We cheerfully give place to the above and humbly beg pardon for not being better posted. I had in mind, when making the statement, that there was no artesian well in the locality around and about Huntington, where my property is located. If I am mistaken in this I should be *very glad* to be corrected.

A. I. R.

Kind Words from Our Customers.

MILES APART ON EARTH, BUT CLOSE NEIGHBORS IN HEAVEN.

Dear Friend and Brother in Christ Jesus:—We are a good many miles apart here on earth; but when I read your writings in the Home department it is an inspiration. It seems to set the "joy bells" ringing, and makes us close neighbors in heaven. May the Lord bless you, and give you health and strength for years to come to help convert this country to Jesus. The old saloon serpent is dying a mighty hard death in Oklahoma, but the temperance people are on top, praise the Lord. Law and order, and love for God and home predominate in Oklahoma.

Perkins, Okla., July 28.

Z. S. HOSSELTON.

HOW GLEANINGS IN ITS MISSION ALL OVER THE WORLD HELPS PEOPLE.

In reading GLEANINGS for three years I noticed you had an agent in Dunedin, New Zealand. I had a sister who went to New Zealand in an early day, and her address I did not know and she did not know mine. The thought struck me if I could get an advertisement in some prominent paper in the island I might find her. So I asked the Box Co. in Dunedin to put in an advertisement I sent to them, and I would stand all expense. So in time I got a copy of the Otago *Daily Times*, with my advertisement in it, and a letter from my sister, one from her son, and one from the Alliance Box Co., telling me what they had done for me, and how much they were out of pocket, and said if I would hand it to you folks it would be all the same to them.

Pipestone, Minn.

FRASER MACKAY.

FOLKS WHO LIVE IN "GLASS HOUSES."

Fie on you, Bro. Root, after your scolding screed of a short time ago, on the carelessness of us poor chicken "journalists," to allow The A. I. Root Company (p. 8) to print the Almighty with a small g! (p. 94, Feb. 1). What will the Lord think of it? and from GLEANINGS!

Henville.

I. KETCHUM.

[Friend K., I "own up" and thank you for your very kind reproof. I want to say, however, that there is no difficulty in understanding what our good friend wanted to say, even if he did use a small G, whereas if a line is misplaced or omitted entirely it makes the whole sentence unintelligible. Our old and faithful proofreader, "W. P.," writes me he marked the above for correction; but our people, being behind hand, and rushed with the February issue, it got off without the correction being made. If the A. I. R. Co. lets this thing go on they will have to "take their medicine" like all the rest of us poor blundering mortals].

Convention Notices.

The North Texas Beekeepers' Association will hold its 31st meeting at Greenville, Texas, on the first Wednesday and Thursday in April, 1912. All beekeepers are cordially invited to attend. We are expecting to have a great meeting.

Greenville, Texas.

W. H. WHITE, Sec.

The annual meeting of the Connecticut Beekeepers' Association will be held Saturday, April 13, 1912, at Y. M. C. A. building. Good speaking. The matter of forming a branch of the National Association will be considered.

Hartford.

CHEAP HONEY FOR MANUFACTURING PURPOSES.

AN intimation has come to us that the bakers have discovered a new recipe by which they can use a cheaper substitute for extracted honey in their manufactured products. Honey gives, as is well known, in cooking, a lasting quality to the cakes, because it makes them keep almost indefinitely. Hitherto, it is said, no artificial substitute has been found to take its place; but we can not believe that there is any thing that can be made by man that will take the place of honey. Some of the bakers, perhaps, may put up a bluff that they have discovered something better and cheaper than honey for the purpose of getting honey for less money. We await results.

DR. WILEY RESIGNS.

It is with much regret that we note that Dr. Wiley has resigned from his position as Chief of the Bureau of Chemistry—a position that he has filled so faithfully for 29 years. According to the newspaper account, the action was entirely voluntary on his part. He was completely exonerated from all guilt in connection with the charges that were brought against him; but he felt that his sphere of usefulness was limited, since the same parties might accuse him unjustly again, and so hamper him that he would be unable to give his undivided attention to his work.

We understand that he does not intend to withdraw entirely from this kind of work; in fact, we believe he expects to do more of it than ever before, except that he will be established with an office in Washington, but not in the employ of the government. We certainly wish him success, for it is to the interest of the American people that he succeed.

We believe the United States Government has lost one of its most efficient workers—one who believed in going ahead when he thought he was right, even though the stand he took might bring trouble to himself. Would that there were more fearless officials.

MUCH INTEREST IN OUR AUTOMOBILE NUMBER.

WE have almost enough material on hand to get out another special number on automobiles if we chose to do so. Some very fine illustrations (over a dozen of them from as many different beekeepers), came in too late. There is, apparently, far more interest shown in the subject than we had anticipated. But when we stop to think about it, it is not at all strange; for there is no class of producers to whom the motor vehicle is more an absolute necessity than beekeepers.

Possibly another year it would be well for us to issue another special number on this subject; but at present we have such a wealth of good material along other lines for special numbers to come, as well as for our regular numbers, that we feel that we can not devote very much more space to this question, interesting as it is.

ANOTHER SWEET-CLOVER PAMPHLET.

THE Bokhara Seed Company, Falmouth, Ky., has just issued a sweet-clover pamphlet, entitled "Sweet Clover and How to Grow It," by E. E. Barton, a member of the American Breeders' Association. A description of the plant is given, including the white sweet clover, the biennial yellow sweet clover, and several other varieties less common. This description is given in such plain simple language that anybody can understand it. For instance, the nature of the plant is explained in that, with red clover, alfalfa, beans, peas, and numerous other kindred species, it belongs to the family of plants called legumes; "a group whose importance to agriculture is beginning to be recognized the world over, and which furnishes in a large measure the food supply of both man and beast, as well as constituting the main stay of the soil's fertility."

The uses of sweet clover are mentioned, and the great value it has in supplying the two things most needed by the greater number of farms—nitrogen and humus. Its value for pasturing and for hay is also brought out. "While alfalfa hay is rather active on the kidneys and bowels of horses, sweet clover has a slight corrective influence

in that regard; and for this reason it is desirable to mix sweet clover with alfalfa meadows, resulting in a more satisfactory hay, as well as assisting the inoculation of the soil where alfalfa is getting a start. On account of the frequent mowings of the alfalfa, the sweet clover will not be able to reseed, and will disappear from the alfalfa at the end of the second year."

The value of this plant for honey was not overlooked, and the different varieties were compared as to their value to beekeepers. Then follow full particulars in regard to the seed and methods of sowing; the best time of year for sowing, the amount of seed, the nurse crop, etc.

All this goes to show that farmers everywhere are waking up to the value of this once despised *weed*, and are calling for the seed to such an extent that the seed companies are getting out these special pamphlets. For further particulars regarding the special pamphlet mentioned above, address The Bokhara Seed Company, Falmouth, Ky.

HOW THE BEES HAVE WINTERED.

As in former years, we find it difficult to give a comprehensive report of the prospects of the season; for, although we have hundreds of reports, there are not enough in any one State to give conclusive evidence. On account of the influence of local conditions, these reports from localities, often only a few miles apart, are more or less conflicting. It is still too early for any thing definite from Canada. We will take up the States that we have heard from, one by one.

CALIFORNIA.

The early reports were any thing but hopeful. During the fore part of March there were good rains; but while most of the beekeepers feel somewhat better over the outlook it is doubtful whether a bumper crop will be produced in any part of the State, owing to the rains having come so late.

CONNECTICUT.

Few reports. Very few days when bees could fly, but apparently most colonies have come through in very good condition.

FLORIDA.

There is every indication now that there will be a fine crop of honey throughout Florida. While the winter was a little backward, the cold did no damage, and the copious rains have put every thing on the boom. In the vicinity of Bradenton, the orange blossoms opened up March 18.

GEORGIA.

The outlook has changed but very little from that given in our last issue.

ILLINOIS.

Reports are rather unfavorable. Colonies in cellars appear to be all right; but those wintered out of doors have suffered losses all the way up to 75 per cent. One apiary of 58 colonies, all dead.

INDIANA.

Most colonies, wintered outside without protection, dead. Colonies in cellars and those well protected, and in good shape in the fall, are all right. Losses average about the same as in Illinois.

IOWA.

Heavy loss in most parts of the State, ranging from 40 to 60 per cent, and, in some instances, worse yet. Considerable honey dew gathered last fall.

KANSAS.

Loss of colonies in single-walled hives close to 25 per cent.

KENTUCKY.

Few reports. Loss of colonies in single-walled hives, possibly 50 per cent.

MAINE.

The few reports are all favorable.

MARYLAND AND MASSACHUSETTS.

Losses apparently not severe.

MICHIGAN.

Reports quite favorable, with the exception of one loss of 39 per cent. In another apiary, all colonies in fairly good shape with the exception of the golden Italians, which are nearly all dead.

MINNESOTA.

Half of the reports show favorable wintering, the others indicating a loss approaching seventy-five per cent.

MISSISSIPPI.

Excellent prospects for good crop.

MISSOURI.

Colonies in good shape in fall, all right. Those without protection wintered very poorly.

MONTANA.

The few reports received are very favorable.

NEBRASKA.

Heaviest loss in years.

NEW HAMPSHIRE.

Losses very light, as a rule.

NEW YORK.

Large number of reports show that losses are apparently light. Colonies in cellars in good shape.

OHIO.

Many reports, most of which are favorable. In one or two localities loss approaches 60 per cent.

OKLAHOMA.

Few reports. Loss possibly 33 per cent.

PENNSYLVANIA.

About half of the reports indicate serious loss. Causes—starvation, insufficient packing, long-continued cold, etc.

RHODE ISLAND.

Few reports. No serious losses as yet.

SOUTH DAKOTA.

Few reports. Outdoors, 30 to 75 per cent loss. Cellar, 10 to 25 per cent.

TENNESSEE.

In some parts, owing to poor quality of stores and no packing, loss is quite heavy. Other reports more favorable.

TEXAS.

Good season expected.

VERMONT.

Few reports indicate close to 50 per cent loss.

VIRGINIA.

Few reports. No serious losses.

WASHINGTON.

Apparently little loss.

WEST VIRGINIA.

Most reports indicate a loss of about one-third.

WISCONSIN.

All reports agree on quite heavy loss out of doors; and, in some instances, in cellars also.

In looking over these reports, the reader must remember that much depends upon the weather from this time on. Just now (March 25) there is nearly ten inches of snow on the ground in this locality, the result of a March blizzard. If the weather turns very warm suddenly, and then gets colder again after a couple of weeks, the brood that will have been started may chill. In two weeks the conditions may have taken a decided turn one way or another.

Look out for spring dwindling. This spring we expect to hear of an unusual amount of trouble from this source for the weak colonies will not stand very much.

THE VALUE OF HONEY BECOMING BETTER KNOWN.

THERE have been so many sensational stories published in the press regarding bees and honey that have been misleading and untruthful that it is quite refreshing to find occasionally an item that is true as well as interesting. The following, from *The Christian Herald*, indicates that the original writer knew what he was talking about, in this instance at least:

HONEY BREAD.

In Europe, where the food value of honey seems to be much better understood than in the United States, enormous quantities are used. Of late years we seem to be waking to a realization of the value of honey as a wholesome and delicious article of food, and also as to its preservative qualities. Cakes and sweetbreads made with sugar soon become dry and crumbly, and to get the good of them must be eaten when fresh; but when made up with honey they seem to retain their freshness indefinitely. In France honey bread a year or eighteen months old is preferred to that just made. They say, "It has ripened." It is the preservative, or, rather, the unchanging quality of honey that makes it so popular with the best confectioners.

As pointed out in the introduction to our new booklet, "The Use of Honey in Cooking," cakes and cookies made with honey retain their moisture and freshness almost indefinitely—a fact which is not appreciated by the general public. It is a question, however, whether the average housewife, on reading this clipping, would put very much faith in it, since she has been fooled so often. At the same time, we are glad to see items appearing in which honey is given its just dues. Let the good work go on.

WHAT MAKE OF AUTOMOBILE TO BUY.

THE various articles in this special number show conclusively, we think, that automobiles are cheaper than horses when the saving of time is taken into consideration. In fact, each user of a machine is so enthusiastic and so sure that his own is the best make to buy that a prospective customer is likely to be confused and unable to decide which way to turn. For the benefit of such we may say that there is no longer any great risk in buying a machine made by a well-established firm that has been in the business long enough to know what is required of a motor vehicle in the hands of an experienced driver and running on all kinds of roads. There is quite an advantage, however, in purchasing from a local dealer if possible, for he will not only see that his customer is taught to run the car but will take an interest, in most cases at least, in seeing that it is satisfactory in every respect. Many dealers handle more than one car, and usually the various makes they sell are quite different. It may be well, therefore, to consider briefly some of the different types; for after all a great deal depends on personal preference. A car that would exactly suit one person might not be satisfactory to the next one, even though the work required were the same.

AIR-COOLED VERSUS WATER-COOLED CYLINDERS.

Some gasoline-engines are air-cooled and others are water-cooled, and we are asked repeatedly which method of cooling is the better. For small cylinders, air-cooling is quite satisfactory. There is no radiator to leak, and no pump to get out of order. On the other hand, the air-cooled automobile engine is not as quiet as the water-cooled, and it requires a somewhat greater quantity and better quality of lubricating oil. If of the four-cycle type, the exhaust valves are also a little more likely to warp with the heat, and give trouble about leaking, than if the cylinders and valve chambers are cooled by a water-jacket. And there is not as much trouble from leaks in water-cooling systems as there used to be, for the manufacturers have abandoned the use of steel in the radiators, pipes, and tanks; and the rubber hose, if used at all, is of good quality, so that it is strong and durable. It is true that air-cooled cylinders will never freeze in cold weather; but there is now no excuse for allowing water-cooled cylinders to freeze, for it is very easy to make an anti-freeze solution with either wood alcohol or glycerine mixed with water.

TWO-CYCLE VS. FOUR-CYCLE AUTOMOBILE ENGINES.

There has been a vast amount of discussion between automobile designers regarding the two-cycle engine—that is, one in which there are two strokes of the piston in the complete cycle, as against the one in which there are four strokes in the complete cycle like the average automobile engine. The four-cycle engine has an inlet and exhaust valve for each cylinder. The operation is something like this: The gasoline vapor is fired by the electric spark, and the force of this charge drives the piston down or away from the cylinder head, and the momentum of the flywheel carries it back again, when the exhaust valve opens and the burnt gases escape. As the piston starts down again, still carried by the momentum of the flywheel, the inlet valve opens, and a fresh charge of gas is drawn into the cylinder. When the piston returns, this charge is compressed, ready to be fired once more, thus completing the cycle. Thus, there are four strokes of the piston in the complete cycle. In the two-cycle engine the piston acts as its own valve, allowing the burnt gases to escape through a port in the cylinder, which is uncovered when the piston reaches nearly the limit of its stroke; and when it moves back again toward the cylinder head a fresh charge which was drawn in is being compressed ready to be fired, so that there are only two strokes of the piston completing the cycle.

Four-cycle engines are much more complicated, but they are more efficient; that is, they will develop a certain horse-power on a smaller amount of gasoline than would be used by a two-cycle engine of the same horse-power. For this reason, perhaps, and

also because the average four-cycle engine is somewhat more easily controlled, and steadier in running, a very large proportion of the manufacturers use this type.

Among the advantages that may be mentioned of the two-cycle engine are the simplicity, the ease of lubrication (for the oil may be mixed with the gasoline), and the fact that the two-cycle engine of a given horse-power is lighter than a four-cycle engine developing the same power. In the past, quite a number of cars having two-cycle engines that were poorly designed turned out to be failures, and this has caused considerable prejudice against this type of engine, which is not well founded, in view of the fact that there are some manufacturers who for years have built good reliable automobiles in which this engine is used.

THE TRANSMISSION QUESTION.

The weakest point in most cars is the transmission, which changes the ratio of drive between the engine and the wheels. It would be impossible to go into even a brief discussion of the merits of the different types of transmission used; but we will say that all forms of transmission have their faults and their limitations. For instance, the planetary transmission which is simple to operate is limited to two speeds forward only. It is difficult to learn to operate properly the sliding-gear transmission that is used on the majority of cars manufactured, and the gears are short-lived unless equipped with the very best bearings. The friction transmission which is the easiest to operate of all is expensive to build, and slightly less efficient than either of the other two drives; and this loss, though so small that it can not be detected in the running of the car nor in the amount of gasoline used, has caused considerable prejudice. This point is more fully discussed elsewhere in this issue.

SOLID VS. PNEUMATIC TIRES.

We are asked quite often as to the merits of solid tires as compared with pneumatic ones. The solid tires are perfectly satisfactory for motor trucks, wagons, etc., where the speed is not over fifteen miles per hour. They are lower in first cost, the expense of upkeep is less, and they never give serious trouble on the road. Pneumatic tires, however, are much to be preferred for pleasure cars, as they ride easier, and they are much easier on the mechanism of the car, since the machinery is subject to much less vibration when they are used.

THREE RELIABLE TRUCKS.

After the foregoing, it may seem like an impossibility to recommend any special car; but owing to the fact that so many have asked for advice, we desire to mention here three trucks—the Reo, the International Harvester, and the Chase. These are built especially for business, and we can give them our unqualified endorsement. The designs of these three machines are quite different from each other; but we have no hesitancy in recommending any one of them.

There are undoubtedly other motor wagons or trucks that are perfectly satisfactory; but these particular machines are to be seen in service every day on the streets of most of our larger cities as well as on country roads, saving time for busy farmers, and we believe them to be particularly adapted for beekeepers.

We have had personal experience with the Reo. For instance, the one shown in our cover picture of this issue was purchased in 1906. For four years it was used as a pleasure car, being fitted with a folding rear seat. The last two years it has been used as a general truck, the body shown being built here. It would be impossible to say how many miles this machine has traveled, but 15,000 would not be far out of the way. The original price was only \$650, so it can be seen that the investment for this distance traveled has not been great. The repairs have been rather below normal if any thing; and, although the machine needs a general overhauling now, it is still capable of considerably more hard work. The 1912 model truck is shown on page 196.

The International auto wagon made by the International Harvester Company of America, Chicago, Ill., is used by the thousands by farmers and business men of all classes. It is equipped with a 20 h. p. two-cylinder opposed, air-cooled engine, which has had to be altered very little in design during the past few years, showing that it has proved very satisfactory in the hands of the users. The high wheels and solid tires make it possible to drive in mud or sand. In this connection, notice what Mr. Polhemus has to say, pages 204-206.

The Chase motor truck is sold in perhaps larger quantities for commercial purposes than any other one make. Mr. Peterson's report of his success with this truck on page 200 is not an unqualified endorsement, but it must be remembered that the one which he has is a very old model. Those turned out by the Chase Motor Truck Company, Syracuse, N. Y., at the present time are being bought in large numbers by such large corporations as the Bell Telephone Company, etc. This car has one of the simplest engines that we have ever seen. For instance, 167 parts found in the ordinary four-cylinder, four-cycle, water-cooled engine are eliminated in this three-cylinder, two-cycle, air-cooled motor, and it is a motor that "delivers the goods" too.

Occasionally, bargains may be picked up in second-hand cars; but as a rule they prove to be a big expense for a year or two; and then have to be sold for almost nothing. Then there is always the danger that the former owner, through abuse, may have weakened some vital part, such as the steering knuckles, or axles, which may give out at any time without warning. The owner who drives the machine himself knows just how he has driven it, and, therefore, knows what to expect. As a rule, we believe that new cars prove to be more satisfactory in the end.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

J. E. CRANE, that paragraph of yours, p. 153, about the beauty of flowers, thrilled me. Shake, old fellow, shake!

OF ALL the appropriate things said about Prof. Cook in last GLEANINGS, none is more appropriate than the one which calls him *lovable*.

MISS MATHILDE CANDLER had much experience with carbolic cloths as super-clearers before the advent of the Porter escape. They do the work quickly and efficiently, but sometimes kill brood. Have our British friends ever observed this?—*American Bee Journal*, 73.

A. C. MILLER thinks bees leave supers for brood-nest cold nights to warm their feet; J. E. Crane thinks it's to warm the brood. If I may risk butting in, I think both are right. The Creator sends them down to warm the brood and they think they're doing it to warm their toes.

GEO. M. STEELE wants me to retract that statement, p. 126, "We do not believe there are a dozen colonies showing *all* five banders in all the United States." He thinks he can produce the goods. But, friend Steele, I didn't say that. It was the editor. Go for him. I have troubles of my own.

MR. EDITOR, I see you have "honeybee," p. 154. The dictionary says "honey-bee." But the dictionary has only been waiting for you to make the lead, and will be glad to make the change. Two words used as one word should be joined by a hyphen; then when the word has passed its novitiate the hyphen should be thrown away, leaving the word all in one. A number of bee-terms should be thus shortened, as topbar, queen-cell, beekeeper, etc.

AFTER ALL, the frantic efforts to clear the four murderers, mentioned on page 119, only succeeded in postponing the hanging a few days. They were hanged Feb. 16. Whether death or imprisonment be the punishment for murder in any given State, the great thing needed is promptness, both in conviction and execution of sentence. While I believe in capital punishment, I believe a man would hesitate more about committing murder if he were sure he would be securely imprisoned for life within a month of the murder, with no chance of a subsequent pardon, than he would if death were the penalty with nine chances in ten that he would get off scot free.

A STUDY of those census figures, page 68, brings some surprises. One would hardly guess that West Virginia would head the list as the State having most bees to the square mile rather than one of those we call great honey States, such as Texas and California. As a matter of fact these come 24th and 26th on the list. Let us place the bees of each

State in apiaries of 100 colonies each, and then distribute them evenly over the State. Then make a list, giving each State its number in the list, and the number of miles apart its 100-colony apiaries will be. Here are some of those at each end of the list:

1. West Virginia, 4.7; 2. Kentucky, 5.1; 3. North Carolina, 5.2; 4. Tennessee, 5.3; 5. New York, 5.6; 6. Delaware, 5.7; 7. Missouri, 5.8; 46. Nebraska, 36.5; 47. Wyoming, 46.2; 48. Montana, 48.0; 49. North Dakota, 119.6.

Doesn't look as if North Dakota beekeepers would be very sociable at a distance of nearly 120 miles apart, does it?

Take it another way. In these same States establish apiaries $3\frac{1}{2}$ miles apart all over the State, and then divide the bees of the State equally among these apiaries. Here's the number of colonies that will be in each apiary of each State:

West Virginia, 44.66; Kentucky, 37.87; North Carolina, 36.17; Tennessee, 34.36; New York, 31.80; Delaware, 31.27; Missouri, 29.28; Nebraska, .76; Wyoming, .47; Montana, .43; North Dakota, .07.

Pity those statistics are not full and entirely reliable.

BROTHER DOOLITTLE has made a good job of showing up the importance of having many bees rather than many colonies, page 102. No one who has given the matter much thought will dispute that it takes a larger *proportion* of the bees of a weak colony to stay at home and keep the brood warm than of a strong colony. I feel a good bit like going a step further and saying that at least in some cases the absolute number required to stay at home in the strong colony is less than in the weak. Take a colony of 20,000 bees, and there may be a day warm enough to work on the flowers, but so cool that 10,000 of those 20,000 bees must stay at home or the brood will be chilled. Close by it is a colony of 80,000 bees, with brood in proportion. On that same day only 5000 bees will be needed to stay home for the purpose of keeping the brood warm. (Just now we're not considering at all the number required to stay home to feed the youngsters.) Please bear in mind that sealed brood is a producer of heat, and when a big lot of it is massed together very few mature bees are needed to keep the brood warm enough. Put it another way. Fill a hive with combs entirely filled with sealed brood, but not a bee in the hive outside the cells. Let the weather be warm enough so that none of that brood will chill, but cool enough so that, if it were any cooler, the brood would chill. Now in another hive at the same time let there be a single frame of sealed brood, and that frame will certainly be chilled. It's hard to hammer too much on the importance of having colonies *strong*.

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Colo.

In an apiary of 105 colonies, half of which are being wintered in double-story eight and ten frame hives, and half in single-story eight and ten frame hives, four colonies up to date, February 15, have died. These four colonies were all in single-story hives.

SPRING MEETING OF THE COLORADO STATE BEEKEEPERS' ASSOCIATION.

With the idea of uniting the interests of beekeepers on the western slope and Eastern Colorado, a spring meeting will be held in Montrose, probably early in May. The date will be announced a little later. The Montrose County Beekeepers' Association is to be our host, and they have promised us a good time. There will be a picnic and various other entertaining features. Every beekeeper on the eastern side of the Rockies should make it a point to attend this meeting. There will be special rates on the railroads, and this will be an excellent time to see the western-slope country. Montrose County is as good a section of Colorado as one will find in riding over a good many hundred miles of Colorado rails. The county is young yet, and has hardly begun to grow.

The orchards are mostly on the mesas, which rise a hundred feet or more above the valley. The freezes are said to slide down hill; but they so often come in the night that they can not find the edge of the mesa, and so camp out in the orchards unless the ever watchful orchardist smokes them out, when they slip downhill and nip the alfalfa bloom of the diversified farmer in the valley. The farmer who is content to raise alfalfa, wheat, onions, and spuds, and does not go in for the \$500 per acre (?) profits in orcharding, is supposed to have lost caste in this country; but upon inquiry I found that the reason for their losing caste is principally because these diversified farmers are holding most of the mortgages on the fruit ranches, and also sitting in the bank directors' chairs! Montrose County is worth seeing. I can't tell it all. Go yourself and see where weeds grow like trees, and the pumpkin-patch is used by small boys to play hide and seek in. Why, I saw a pumpkin that weighed 147 lbs., and it wasn't fed milk either. It just had all the Gunnison water and black soil and Colorado sunshine it wanted.

PARCELS POST NOW AN ISSUE.

In taking up this question of parcels post, there are two things that should be thoroughly understood: First, every express company is operating in violation of the law. Second, the law has been violated so long that nearly everybody has forgotten about it. Here is a part of it: "And declares it to be unlawful for any person or persons to establish any private express or expresses for the conveyance, or in any man-

ner cause to be conveyed, or to provide for the conveyance or transportation by regular trips, or at stated periods or intervals, from one city, town, or other place, to any other city, town, or other places in the United States between and from and to which cities, towns, and other places the United States mail is regularly transported under the authority of the Postoffice Department, of any letter or *packages*, or packages of letters, or other properly transmittable matter in the United States mail, except newspapers, pamphlets, magazines, and periodicals. A penalty of \$150 is inflicted by the act for its violation."

The parcels-post limit now is four pounds, and the rate 16 cents a pound; but the rate for beans, peas, seeds, etc., for planting is 8 cents a pound. If for human consumption, the charge is 16 cents a pound; the charge is twice as much if the beans are to be eaten as if they are to be planted. Talk about the high cost of living!

Now, suppose the express companies receive an 11-pound package from Great Britain's parcels post. They will deliver it anywhere in the United States for 24 cents; while if we want to send it by post our Postoffice Department charges us 16 cents a pound, and we have to divide it up into four-pound packages.

The postoffice in Boulder will charge me 64 cents on a four-pound package to New York; but if I send it to Berlin (through New York), the charge is only 48 cents.

There is no limit to the size of package carried by parcels post in Switzerland, and the rate is one cent a pound. In Belgium the limit is 132 pounds, and the rate about 1½ cents a pound. Germany will carry by post up to 110 lbs. at a rate of about 1¼ cents a pound. Austria will do the same. France will carry up to 22 lbs. at 1½ cents a pound. But we here in the United States have to pay 16 cents a pound, and can send but 4 lbs. Mexico, which owns 51 per cent of the express companies' stock, will carry parcels at half the rates charged here.

The average rural-delivery carrier's load is 25 lbs. It should be nearly a thousand pounds, and would be, under an intelligent parcels post. The rates could be put down, and it would not be long before we could have rates almost as reasonable as those in Europe. And, in addition, we can, from the additional profits, soon have the penny letter postage.

The express companies have been paying dividends of 38 per cent, and this is made through a violation of the law. What are you going to do about it? I would suggest that you write your Senators and Congressmen at once, urging them to support a progressive parcels-post measure. It will mean several dollars a year to you, as you will readily appreciate as soon as this betterment is in operation.

NOTES FROM CANADA

J. L. BYER, Mt. Joy, Ont.

I am glad to note, Mr. Editor, that you have reached the point where you do not say that a sealed cover is *absolutely* the best thing for our colder climate, and I confidently expect to see in the near future that you will be quite *sure* they are not at all desirable, and that a dry *porous* material next to the bees is altogether to be preferred for outdoor wintering.

These notes are written March 11, and this month so far seems likely to keep up the record for cold weather that has been established by the two months preceding. While every day in March has been fine and clear—bright sunshine prevailing about all the time, with no storms whatever—yet for all that, on eight mornings out of the eleven the thermometer has registered from zero to five below.

P. C. Chadwick says, page 101, Feb. 15, that the average mortality of bees in California is ten per cent per annum. If that is correct, a lot of the talk about the wintering problem in the North is exaggerated, comparatively speaking, for many beekeepers in the colder climates do not lose more than that annually. In fact, I have good reason to believe that some of those who pay close attention to requeening, etc., do not have as high a rate of mortality as that.

By the way, the Feb. 15th issue is quite a "chicken special," and, judging from the different articles given, many beekeepers are "chickenkeepers" as well. One of our most successful men in Ontario combines chickens, bees, and fruit, and he certainly makes good in all three branches. Just a question whether a combination like that is not better for many than "keeping more bees." No doubt all will depend on the makeup of the man who is most concerned in the matter.

In reference to G. H. Bedford's plan of finding queens, p. 720, Dec. 1, the plan certainly looks easy. However, if they drive up as easily as he intimates, I would prefer to allow bees, queens, and all to go right up, with no excluder to hinder their progress. Then I would invert the prepared crate with the wire-cloth sides, and drive the bees down through an excluder into the hives again. In that way it seems to me that the queen would be sure to be found. If I relied on finding her trying to get up through the zinc I am afraid she would be overlooked too often.

Every year about this time, or earlier, reports appear from different sections further south, to the effect that the bees have been shut in five or six weeks without having a flight, and the fear is expressed that loss

will result from this cause. What has always puzzled me is, why a few weeks should work disaster, when we in the North often go from four to five months without having a day that the bees can take a cleansing flight. This present season our bees have not had a flight for three months, and during all that time we have had more zero weather than many of us have ever experienced before. Yet for all that, the bees appear to be wintering all right outdoors; and if we should have a good day in the near future, I do not look for very heavy losses. The exception in my own apiaries will be almost altogether confined to the 20 hives I mentioned in the February 1st issue as being wintered with no packing, the hives being constructed with double boarding with heavy paper between the two.

Regarding protection of apiaries in the matter of windbreaks, I must disagree most emphatically with friend Holtermann when he sanctions high board fences for that purpose. While I would sooner have a high board fence than *nothing*, still it would be my last resort. My favorite location, when it can be secured, is a site some distance south of a row of evergreens, with the bees in an orchard if possible. One of my apiaries has evergreens on the north, east, and west sides, and is right in an apple orchard. The protection is about as near ideal as possible. Another yard is also in an orchard, and has a row of evergreens on the north side. Still another yard is in an orchard; but instead of evergreens the farm buildings are on the north side about ten rods away, and this breaks the north winds. In all three yards the bees winter well as a rule. At the home yard there is a high board fence, and I certainly do not compare it with the evergreens so far as giving shelter to the apiary.

About the middle of February we had a day that was *almost* warm enough for the bees to take a flight; but the wind was blowing cold from the north, although the sun was shining brightly. In spite of any thing we could do to prevent it, a number of colonies got stirred up, and a few bees came out of the hives. Wherever the bees fell on the snow where the sun would strike them, they got up and flew again; but if they fell in the shade they were done for. Toward evening I happened to take a look on the north side of the board fence, and there was a distinct line made by the dead bees that fell within the space nearest the fence that the sun did not strike. Scarcely a bee was on the snow beyond that line, but for eight or ten feet all along the fence there were hundreds of bees. With a protection higher than the fence, and further away from the yard, the conditions that caused the loss of so many bees are done away with.

Conversations with Doolittle

At Borodino, New York

TRANSFERRING BEES.

"In some frames which I have bought the combs run from one frame to another to such an extent that I can not get any of them out without tearing them or the combs, or both. Please give something in GLEANINGS regarding such a state of affairs."

As I frequently receive letters of a similar nature, it may be well to devote a little time to this subject, even though it is a matter which has often been written about, and one found in practical books on bee culture. Our questioner puts the matter of crooked combs very strongly, for I have yet to see that colony of bees whose combs are so very crooked, or which run across the frames so badly that they can not be utilized in transferring to other frames, and the frames they were in at first remain fairly good after the combs are cut from them, so that they can receive the combs from the second colony worked upon.

The first thing necessary is to decide on the time to do this work. My time has always been during the blossoming of the apple trees, for at this season there is little honey in the way, and the combs are not very full of brood unless there is an earlier yield of nectar. With the first flow of nectar to a sufficient extent to attract the bees into the fields in large numbers, and to enable them to secrete wax enough to fasten the combs together, and to the frames, is the right time. Drive the bees away from the sides of the hive to which the combs are attached, and with a long knife or chisel cut these attachments so that nothing holds to the hive save where the ends of the frames rest. Next blow smoke enough over the tops of the frames to drive the bees off. Turn the hive bottom side up at once on an old blanket. By this time the bees will have become demoralized and quite well filled with honey. Place a box over the bottom of the hive, and give a few strokes either with the fists or with some sticks. The bees will at once proceed to run up into the box, and in a few minutes all will cluster there.

This box of bees can then be set on the old stand, the old hive lifted off the whole mass of combs and frames, and the work of cutting out the combs to the best advantage and fitting all the worker comb into frames can be started. When all are nicely fitted into the new frames, and these frames put in the old hive (if that is good enough to use, or if not, in a new one), this hive containing those combs which are judged useful should be set on the old stand, and the bees from the box hived into it, the same as is done in hiving a natural swarm. If there is not sufficient comb to fill all the frames the hive will hold, a division board is placed next to the last comb put in (a bee

space from it), and the colony kept thus until a time comes when they will work foundation, when frames of foundation are inserted in the vacant space. Or if one happens to have empty combs in frames of the same size, this vacant space can be filled with these at the time of transferring. This is similar to the way our fathers transferred, and the plan used at the great field-day meeting in June, 1906, near Philadelphia, by Prof. Surface who demonstrated before the thousands gathered there at that time.

But there is another way which I consider fully as good, if not better, for modern beekeeping. This latter plan allows the beekeeper to wait till nectar is coming in quite abundantly, or till about the time the bees swarm naturally, when a new hive with a full set of frames filled with comb foundation is prepared the same as if hiving a natural swarm on frames filled in this way. This new hive is set on the stand of the colony which is to be transferred, and most of the bees and the queen are driven into a box as before, only the hive and combs are not disturbed by cutting or otherwise. After the queen and about two-thirds of the bees are in the box, the old hive is removed to a new stand, and the bees are hived from the box into this new hive as before. They will at once draw out the foundation in the frames, and the hive will soon be completely filled with the very best worker combs possible, and a good colony for securing surplus honey. In 21 days in the old hive with crooked combs will be a young queen about to begin to lay, or already doing so. The worker brood will have emerged from their cells, and every thing will be in shape for another transfer. The process is the same as the first, except that now *all* the bees are driven off their combs and hived in another new hive, prepared as was the first. We now have these old crooked combs where we can do what we please with them, while the bees are all on (or will be as soon as the foundation is drawn) the very best all straight worker combs, such as make the eyes of any apiarist sparkle with delight.

Now, what shall be done with these old crooked combs? Some say dump the whole thing into the solar wax extractor, and let the sun separate the combs from the frames and the wax from the honey, as all can then be used to better advantage than in any other way. Without question, this is the easiest way out; but some way the heart of the one who commenced his beekeeping life between 30 and 50 years ago, before the advent of comb foundation, when every inch of worker comb was considered very valuable, still considers such comb of more worth than the wax it contains, therefore he generally fits all of the best of it into frames for use again.

General Correspondence

INTERNATIONAL AUTO WAGON SAVES EXPENSE OF HIRED MAN

BY N. L. HENTHORNE

In this section of Colorado, thirty-five miles north of Denver, in the Platte Valley, bee range is rather limited, thus making the maintenance of large apiaries in one location not conducive to the best results. The only alternative is to place from fifty to seventy-five colonies in different places throughout the district. I have between 500 and 600 colonies within a radius of twelve miles from my home, and this necessitates traveling from 100 to 150 miles every week during the swarming season. In order to get the work done I was obliged to keep a man to assist me; and my experience with hired help during the swarming season has been far from satisfactory at the best. The long drives I was compelled to make every day during the summer were very fatiguing, for considerable time was spent on the road alone; and in order to keep the horses in shape I could not overwork them; and the cost of maintaining a driving outfit in this country amounts to about thirty dollars a month.

A very important advantage of a motor vehicle is in getting to a yard and away again with a load of honey. With horses it is always risky if not dangerous.

In view of the objections to horses as given, I became convinced that the automobile is the only means of transportation in the bee business, and I decided to buy one. Upon investigation I learned that I could buy second-hand machines in Denver at prices ranging from \$100 to \$600; but I knew nothing at all about automobiles, and I believe investments in second-hand machinery to be inadvisable at best. Therefore I bought a new truck, manufactured by the International Harvester Company, the solid tires and the air-cooled cylinders being strong points in its favor, in my estimation. The car is ostensibly built for service; but by adding a rear seat it can be turned into a pleasure car, as it rides quite comfortably.

I held the wheel of my machine for the first time at four o'clock on the afternoon of July 11, 1911. The morning of the 12th I loaded on 72 empty eight-frame comb-honey supers, and ran out 7½ miles into the country, did the necessary work there, and reached home in time for the midday lunch. In the afternoon I went nine miles in another direction, arriving home at 5:30.

Aside from the usual minor troubles of the inexperienced driver, I have had no trouble whatever with the machine; and in the 4000 miles of travel which I have covered with it I have not paid out a cent for repairs aside from one slight accident to the engine. During the summer I can make

the distance of 100 miles with a load on eight gallons of gasoline and one gallon of oil—the former at 14 cents per gallon, and the latter at 48, making a total running expense of \$1.55 per hundred miles. This machine can carry 1500 pounds twelve to fifteen miles per hour, and I have run into Denver with a load of honey, and out with supplies, in one afternoon—a distance of 70 miles, round trip. Mr. Rauchfuss, of the Colorado Honey-producers' Association, will verify my statement that my honey arrived at the association in better condition than any other he received. I now expect to do all my own work this summer with the use of the truck. I can haul from 55 to 65 cases at a trip.

Naturally there will be the expense of new tires in the future. The cost of tires is nine dollars each, put on; but I can say that I have never been delayed a minute because of tire trouble. I have made several trips into the mountains with my truck, and it works well on the mountain roads. I can hardly wait until fishing time comes for a run into the hills. I have used the machine in mud and sand with good success. Like all machinery it requires good care in order to do good work.

Platteville, Colo.

REO DRIVEN TEN THOUSAND MILES WITHOUT REPAIRS.

BY C. A. KINSEY.

Since April, 1911, I have been driving a 1910 25-30 h.p. five-passenger Reo, and have covered between eight and ten thousand miles. I have had no repairs made on the car so far, outside of tires, except to grind down two exhaust valves. The tire expense is something that depends a great deal on the quality of the tire, kind of roads, and, most of all, on the carefulness of the driver.

With this Reo it is possible to start out at 7 o'clock in the morning, with six grown people, two children, nine and ten years of age, lunch-baskets, fishing-tackles, etc., and go 45 miles up a rocky canyon into the heart of the Rocky Mountains, making a rise of nearly 3000 feet, spend a good part of the day fishing and berrying, and get home again at 7 P.M. This car ordinarily will travel 15 miles on one gallon of gasoline. In this Gallatin Valley, surrounded by mountains, there is always an up grade, either going or coming, from 30 to 50 feet per mile. There is one particular road that rises some 1700 feet in a little less than four miles. The Mitchell and the Reo, with favorable conditions, will take this grade on "the high."

I know from personal experience that an auto is a boon to beekeepers. There is no danger from stings and resulting runaways as with horses.

Belgrade, Mont.

REO USED FOR DELIVERING HONEY IN THE WINTER

BY JOHN C. BULL

I use my automobile mostly for delivering honey, as I work the house-to-house trade in the winter. My machine is a Reo two-cylinder five-passenger touring car, with detachable tonneau. I take the tonneau off and put on a box for delivery work. I bought my car second hand after it had been used for about 16 months. I have had it 19 months, and have driven from 5000 to 6000 miles. The territory that I cover selling honey is 30 miles across; and to cover that ground with a horse and wagon would take twice the time. With the auto I can leave headquarters in the morning, drive 10 or 12 miles, then deliver \$75.00 to \$90.00 worth of honey, and be back for supper, while to drive that distance with the average horse would take nearly all the day on the road, considering the loads that I carry, which sometimes amount to 725 lbs. at a trip.

As to cost of upkeep, if the auto is used every day, and the horse the same, I think the cost would be nearly equal, although the auto would cover two or three times as much territory as the horse. The horse requires attention three times a day, while the auto, when not in use, costs nothing; and the time required to keep a car in shape is far less than taking care of a horse. The auto can be looked over and kept in shape at odd times or stormy days, so the time is not missed.

As to reliability, almost any of the standard makes of car have passed out of the experimental stage. In the last two winters I have delivered some 26,000 lbs. of honey with my car, and have never been obliged to find another way to finish up a day's delivering. I use it all winter, through cold, snow, and all kinds of roads. I find I can go almost anywhere a horse-drawn vehicle can. If a man has a car that can be used for pleasure or business both, he will find the pleasure ride is something that can not be measured in dollars and cents.

Any one who has several out-apiaries and lots of traveling to do on the road will find a good automobile the best and most paying investment he can make.

Hammond, Ind.

WHY WE INVESTED IN A MOTOR BICYCLE

BY C. CALVERT

To explain matters, a friend and myself run about two hundred colonies of bees of our own, and we also have the oversight of about sixty colonies belonging to a friend who at present is abroad.

Our own bees are located in various apiaries containing from thirty to fifty colonies each. These apiaries are situated ten, eleven, twenty-two, and forty miles away from this town, so we have found it a weary and exhausting task to make the rounds of all of them on the ordinary bicycle. For example, to cycle nine or more miles up to

the Cotswold Hills, do a heavy day's work, and then to return home on the cycle, perhaps when it is windy, or when the temperature is 90, in the shade is somewhat like hard labor. So we determined to have a motor bicycle with a side car. The seat of the latter is detachable, and an oblong-shaped box with sides a few inches high, and large enough to carry a couple of hives of bees, can be screwed on in place of the seat. This box is also convenient for the conveyance of syrup to the apiaries, and for bringing tins of honey home for bottling. It will, we hope, save a carrier's bill—a serious item to the bee man who does not keep horses. Driven bees, too (a commodity you probably do not know the meaning of in America, where I suppose straw skeps are not used), may be obtained at long distances, and conveyed easily on a motor cycle. It is estimated in this country that such a machine may be run a year at an expense of less than one penny a mile. This is, of course, taking into account petroleum, new tires, breakages, license—in fact, every thing, and it is well-spent money, seeing that it saves, first, the wear and tear of bicycles for two men; and, second, a carrier's bill for conveyance of bee produce, feeding syrup, and appliances, and that it provides a quicker mode of transit to one's work, at which the bee man arrives perfectly cool and fresh, besides getting in two or more extra hours' work a day which otherwise are spent crawling on the ordinary bicycle.

Cheltenham, England.

HAULING HONEY FROM OUTYARDS IN AN E. M. F.

BY ROY TAIT

In the spring, and during the first part of the season, we make the rounds to the outyards once a week in the auto. We leave home about 6 A.M. with extra hives filled with combs or full sheets of foundation, and at about 7:25 I reach our mountain yard, 20 miles away. Our first machine was a Maxwell; but now we have an E. M. F. 30 h. p. model. My next machine will be built to order. It will have an E. M. F. 30 h. p. engine, the Cartecar friction transmission, and the Midland full-floating rear axle—that is, if I can have it built that way. I believe the E. M. F. car as built to-day, with removable tonneau, is the best car on the market for the money—\$1100 at the factory. Its simplicity and durability will at once appeal to the mechanic as well as to the man who knows nothing about machinery.

The greatest nuisance in motoring is the pneumatic tire; but the trouble can be overcome to a certain extent by using inner linings, which prolong the life of the outer casing about one-half.

I would not think of keeping bees in outyards without an automobile. When I read of a man going to dozens of yards with a horse, I wonder.

Grand Junction, Colo.

Wesley Foster and the Brush Runabout, purchased by the State of Colorado for use in bee inspection.

AN AMATEUR AUTOIST

Some Knowledge Gained by Experience with a Brush Runabout

BY WESLEY FOSTER

Automobiles are taking such an important place in the beekeeping world that possibly my first month's experience with one may be interesting and valuable to the owner who is already or soon will be in the same fix that I am. December 1, 1911, I knew almost nothing about autos except that they have been honking at me at every crossing, and throwing dirt and burnt gasoline into my lungs ever since Bryan ran for president. Previous to December I had enjoyed perhaps three rides in automobiles. I had also run my uncle's gasoline-engine to operate a buzz-saw for making some bee supplies. The extent of my knowledge had been in reading advertisements and watching the changing models from year to year. I knew that, to be right up to the times, one must have a new auto about every six months, but I did not know the use of a carbureter, spark plug, magneto, nor the various levers.

On Dec. 1 the State purchased a Brush runabout for my use in bee inspection, and since that time I have been getting acquainted with nuts, burrs, grease of three kinds and oil of two, well scattered over my anatomy and clothes. I have washers and burrs in every pocket, and nuts and screws in my pocketbook.

December 2 I went to Denver to bring the runabout to Boulder. The Overland Auto Co., from whom the auto was purchased, sent a young man along to show me how to run it. We left Denver about 3:30 P.M. for the 32-mile drive to Boulder. The mechanic ran the machine to the outskirts of Denver and slowed up to let me take the steering wheel. A sudden crack, and our plate-glass windshield curled right over the engine shield! The nuts of both braces of the windshield were gone and the bolts were lost. We had not seen that everything was tight before starting.

We took off the windshield, and my companion carried it in his hands the rest of the way. I got along well running the auto on the straight road; but when it came to passing a hay-rack I nearly always forgot for an instant just what to do, and would put on the brake, thus throwing the engine out of gear, so that it would get to "going like sixty," buzzing and singing like a drone. After having passed the team I would release the brake and let the engine back into gear so suddenly as to give it an awful wrench, sending the car ahead with a mighty jerk. Now I have learned how to pass teams with little difficulty and no jerking.

Well, I ran the auto all the way home without the mechanic taking hold of any thing, though he gave me "pointers" and advice several times. The most valuable point for me right at the start was my bicycle experience in holding the handle-bars

The Reo 1500-lb. truck which is equipped with a single-cylinder 12 h. p. motor, planetary transmission, and a 44x72 inch body.

firm, and also A. I. Root's suggestions and caution some time ago about guiding or steering too much.

It was dark when we reached Boulder at 6:15 P.M., and the last twelve miles were driven by using the acetylene-gas lights; but I took the mechanic to the train for his return trip and drove the auto home alone. I did not attempt to run it into the barn by its own power, but pushed it in by hand. I turned out the water by opening the faucet on the engine and radiator so it would not freeze, as we had no anti-freeze mixture in the radiator.

The next morning in reading the instruction book I found that the oil on the dash-oiler should have been turned off. I hurried out to follow out this injunction, but the oil had been running all night, and there must have been nearly a quart in the engine. We had a hard time getting the engine started. We put hot water in the radiator, gasoline in the cylinder, washed the spark plug in gasoline, and primed the carbureter by pulling the little wire provided for this, but the engine would not start until we had worked with it for an hour or more. Then how smoky was the exhaust caused by the burning engine oil! I had three large blisters from cranking the engine, and was tired out when it started.

The next day we could not get the engine to run at all, and called in an auto-repair man. He found that the batteries tested only ten instead of twenty-five. After he put in new batteries all was well. This is a

point to remember: Batteries weaken from becoming old. The batteries in this car were new when they came from the factory, but they had become worthless from standing in the store room. Be sure to have the batteries tested before buying.

The barn in which we keep the auto is so cold that we have been letting the water out from the radiator every night. The faucet is hard to get at, and has a nail hole in which to insert a nail to turn the faucet. To save trouble we thought it would be a good idea to leave the ten-penny nail in there, but soon learned by sad experience to remove it. Three holes had been punched in the sheet-steel dust-guard under the engine.

A five-gallon can of gasoline which we kept at first in the auto back of the seat knocked off several square inches of varnish so now we are wrapping cloths or sacks around every thing we put in behind. The other day we got tired of emptying out the water every day, so we got a gallon of wood alcohol for \$1.00 and made an anti-freeze mixture of 40 per cent wood alcohol and 60 of water. Since then we have been leaving this in the radiator. Some auto men say that this often will not work, so I have been keeping the radiator well protected besides. The Brush has a single-cylinder 10 h. p. engine, and is hard to start when the engine is cold. I have had to jack up one of the rear wheels when starting, as the transmission sticks a little, the car being new. This lets the wheel turn, and the engine will go on the second or third trial. I often have to ad-

vance the spark and pour some gasoline in the cylinder before the engine will start if the day is cold.

The book of instructions says, "Never advance the spark before getting the engine started, as there is danger of a back kick." But as the Brush engine runs opposite to most motors, the result of a back kick would be to throw the hand out of the way, and no damage would be done unless one's knees were in the way. I keep my feet out of the way and have not had a back kick yet.

Most of my trouble has come from not oiling enough. The engine has stopped several times for this reason. On one occasion, when only three blocks from home I looked into the gasoline-tank to find it as dry as a bone; but I managed to run the machine within a block of home on the gas in the tube and carbureter before it stopped. I had to take the gasoline out of our stove to finish the trip, then rush up town and get back with a new supply in time to save the baking which my wife was doing at that time.

One of the beauties of the Brush runabout is that it is so light it can be lifted around by hand. I do not need a jack to lift a wheel. It will run 25 miles on a gallon of gasoline, which costs $12\frac{1}{2}$ cts. at the refinery two miles from our house. On Colorado roads it will run from 15 to 18 miles an hour; and for short spurts, perhaps 25 or 30 miles.

Our Colorado mud has so much alkali that it will dull the varnish; and some small specks that I left on for several days took the varnish off entirely. It will pay every auto owner to remember this. The varnish was taken off from the steel parts, not on wood. Letting out the hot water from the radiator on the varnished steel turned it from black to a bluish color. Oh! one learns fast, I can tell you.

We inspect the auto often, and keep bolts and nuts tight. One of the gasoline-tubes leading to the carbureter began to leak, and we unscrewed this and put some white lead in the threads, screwed it back into place, and it has not leaked since. An auto-repair man told me this.

My father-in-law has helped me grease, oil, and crank and generally fool with the auto. He is also very much interested in chickens. The other day he made a contract to furnish 500 baby chicks, and is planning to buy an incubator. Well, we found that the radi-

ator was not quite full; and so, as the per cent of wood alcohol in the radiator was a little below the 40 per cent average, he took a pint and a half down to pour in; but he was thinking about that incubator, and poured that wood alcohol into the *gasoline-tank!* Well, we asked our all-knowing repair man whether harm would come from such a mixture. He said we had better draw it off and put in new gasoline. It took us an hour to draw it off through the faucet on the under side of the carbureter. We found that the gasoline came to the top, so we poured the top off and threw the wood alcohol away, and are using the gasoline in our stove in the house.

Fully equipped, the Brush costs \$450 in Denver (\$400 at the factory), and the makers say that it can be maintained for three to five dollars a month—a claim that I can well believe. At any rate, it is cheaper by far than a horse, when gasoline and oil are worth $12\frac{1}{2}$ and 50 cts. a gallon respectively. It is a time-saver also, and its ways are as easily learned as the nature of a horse. The Brush has room for an extra seat behind for a few bee supplies. As it is, twenty supers may be carried, but by making an extension box, forty or fifty could be hauled very easily.

Boulder, Colo.

[You will very likely find that you have already had nearly all the trouble that you will have for some time. A beginner with an automobile, as with any thing else, makes a good many blunders at first; but after he becomes accustomed to the car and its eccentricities it will run along very steadily and give practically no trouble—that is, if it is a well-designed machine.

The wood-alcohol solution for an anti-freeze mixture in the radiator does very well if you are careful to test the density of the

J. R. Heaton's Cadillac, which he purchased because of having a very severe attack of automobile fever.

Cadillac owned by R. L. Watkins, Selma, Cal.; bought primarily for a pleasure car, but used constantly in a 600-colony business.

liquid with a hydrometer each time you come in from a run, and add more alcohol if necessary. The point is that the alcohol boils or evaporates much more quickly than the water; and, even in a run of a few miles, enough of the alcohol may evaporate to make the mixture unsafe if the temperature should fall considerably while the car stands for a few hours.

On this account a safer mixture is one made up of equal parts of glycerine and water. This costs more at first but the glycerine does not evaporate, and the mixture may be saved from year to year, kept over summer in jugs, and used again and again. This solution has no bad effect on the metal parts of the cylinders or radiator; and, while some claim that it attacks the rubber-hose connection to a certain extent, this objection does not seem to be a very serious one, for we examined the rubber connections in a car that had been in use three winters and found that the glycerine had not hurt them a particle.—ED.]

THE CADILLAC, USED BY A CALIFORNIA BEE-KEEPER HAVING 600 COLONIES OF BEES

BY R. L. WATKINS

My car is a 1912 model five-passenger Cadillac. I selected this particular make because it seems to be the best car, and the one that has the best equipment of any at a reasonable price. It has electric lights, an electric self-starter, and every manipulation is made from the seat. I have driven it 1400 miles, and have never had a crank on it, and have never had to make an ad-

justment of any kind—have not even had a puncture. It is equipped with oversized tires, 4 x 37, with staggered tread on the rear wheels. A four-cylinder Kellogg air-pump inflates the tires.

I bought the car more for pleasure than any thing else; but I believe it will pay for its upkeep in my business. I have 600 colonies of bees located in ten different yards from four to fifteen miles from home, and I do all the work myself; and with my car it is almost like having them all at home. As the roads are good, it takes only a few minutes to drive fifteen miles. If necessary, I can visit every yard in one day, and have time for considerable work.

Selma, Cal.

AN AUTOMOBILE FOR ALL THE FAMILY

BY J. R. HEATON

In the spring of 1911 my wife and I each had a very severe attack of fever. In fact, all the children had a touch of it too. (There were only five of the children at home at that time, the other four being away.) We lingered along quite a while, but did not seem to get any better. One day our family doctor came by in his auto, and stopped in front of the house where I was mowing the lawn. I went out to have a friendly talk with him, and, in the course of our conversation, the automobile question came up. I told him that we were all about sick; and when he asked about the symptoms I told him I believed we had the automobile fever. That day we decided to cure ourselves of it, or at least to take a dose of medicine for it.

The first thing that we had to decide, after we concluded to buy a machine was what size and what make we would get. I have a large family; and as we wanted a car for pleasure-riding more than any thing else, we decided we would get a five-passenger touring car so that we could take as many as seven persons at a time if some of them were children. We knew that we would have to have plenty of room, so we began to look for a machine having a long wheel-base and one with a roomy body. We knew such a car would cost us between \$1600 and \$2000—a lot of money to put into a thing just to ride in; but we had the fever pretty bad, and we wanted to cure it, even if it did take \$2000.

I had a son in Indianapolis who had gone to the Indiana Automobile College, and who was driving a machine in the city at that time. I thought his judgment would be worth considering, so I went to see him to look for a car that would suit us, and also to get his advice as to what make was the best and cheapest for the money. Indianapolis is a great distributing center for automobiles. One can find any thing in this line from \$350 to \$6000. (I thought one costing less than \$6000 would do for us.) At first we looked at some second-hand cars, as I thought we might find one that would suit us that we could buy cheap, and that would be good enough for a poor man and his family. I found that we were mistaken in this, however, so we turned our attention to the new machines. It would take too

much time to tell all the kinds and makes we looked at. I will only say that when we investigated the Cadillac we thought we had found just the car we had been looking for—one that was built right, was strong and very roomy—one that I would not be ashamed to drive any place in any city. I finally bought the machine, and the agent drove it home for me, as I had never had hold of a steering-wheel in my life.

The distance from Indianapolis to my home is 71 miles, and we made the trip in three hours and five minutes. That was not very fast, to be sure; but it was fast enough. I don't like fast driving. It is dangerous, and one can not see the country. The Cadillac weighs, when empty, 3100 lbs.; but for comfort and easy riding, a rather heavy car, and one having a long wheel base, is the best, for it will not bounce along and bump like a western bronco, which a short machine often does. Of course the real reason why I bought a Cadillac was because I liked it best. It just suited me so far as size was concerned, and I think it is the best car that is made and sold at the price—better, in fact, than many that sell for several hundred dollars more.

The Cadillac has three forward speeds, and I have never yet found a hill that I could not pull on the intermediate or second speed, even with a full load of five passengers. Besides, there are a great many other good features that I will merely mention. For instance, the metal trimmings are all nickel instead of brass. The nickel looks much

Chase motor truck, used by James Peterson, of Corning, Cal., for hauling bees.

Albert Snell, of Clayton, N. Y., in his five-passenger Ford.

better, and it is much easier to keep it looking nice. I have never had to polish the nickel, and the car now looks as good as new.

There are two complete and independent systems of ignition with separate spark plugs for each.

The oiling system seems to be about perfect. The oil is supplied to the crank case of the engine by a force pump which can be regulated so as to keep just the right amount in the case, and not so much as to cause smoking at the exhaust. One never sees the Cadillac going down the road smoking like a fire-engine. I can run one hundred miles with one pint of lubricating oil, and there is not a gear on the machine that does not run in grease or oil. The four wheels that carry the car will run 1000 miles with one greasing. It does not seem as though there could be much wear on any part of the Cadillac with such perfect lubrication.

Some cars use more gasoline than others. I do not know how the Cadillac compares with other machines; but I drove to Indianapolis and back, a distance of 166 miles, and used only nine gallons of gasoline, making about $18\frac{1}{2}$ miles on a gallon. I think this is very good for a heavy machine with a load of five passengers, such as I had.

EXPENSE OF UPKEEP

I have run my car 3082 miles, and it has not cost me a cent for repairs. My tires are in good shape, and I think they are good for 2000 miles more of travel.

The cooling system has never occasioned any worry. The water is forced through the radiator and around the copper water-jackets by a centrifugal pump, and the air is sucked through the radiator by a fan. The water never boils, but does what it is intended to do—keeps the cylinders cool.

Does an automobile pay for a business standpoint? I think it does. An automobile costing \$2000 will travel further than \$2000 worth of horses and carriages, and the upkeep will be less. Besides, much less time is taken, and the traveling is much more comfortable.

This article may sound like an advertisement for the Cadillac; but I have merely given my reason for buying the particular car that I did, and my experience with it.

Rosedale, Ind.

CHASE MOTOR TRUCK USED BY A CALIFORNIA BEEKEEPER

BY JAMES PETERSON

I am sending you a photograph of my automobile, with the last load of bees from an out-apiary. The machine is a Chase delivery wagon equipped with a three-cylinder two-cycle engine which will carry all I can pile in the body, at 15 miles per hour. I have had eight grown persons in it at one time.

This machine is one I bought last fall in Sacramento, paying \$300 for it second-hand. I do not know much about automobiles; but if I had it to do again I believe I would have a car with a four-cycle engine. This machine was not altogether satisfactory until I had a machinist rebuild the timer, since which time I have had no trouble.

The automobile is sting-proof, and saves a great deal of time in going to and from my out-apiary. The cart shown on top of the load is what I use to take the bees over the soft ground to the auto.

Corning, Cal.

[The two-cycle engine—that is, those similar to the motors used in boats—has not

been entirely satisfactory for automobile use in the past; but we understand that the present truck, built by the Chase Motor Truck Co., is giving complete satisfaction. It is still equipped with a three-cylinder air-cooled two-cycle motor, the smaller-sized trucks being fitted with a planetary transmission, and the larger sizes with sliding gear. This is a machine that has passed the experimental stage.—ED.]

— ♦ ♦ ♦ — **TWENTY MILES TO A GALLON IN A FORD**

BY J. H. THOMSON

Though I am a beginner I have sixty colonies, and I like beekeeping. It is a profitable business as well as good for pleasure. From one colony last season I sold \$25.00 worth of comb honey.

I have a five-passenger Ford touring car. I bought a Ford because I believe it to be the best car on the market for the money, and because the expense of upkeep is not so great as on other cars. I average about 20 miles per gallon of gasoline.

I bought the machine for a pleasure car, but find it useful for business too. In the five months I have owned it I have driven it 2550 miles, and three of the tires have not yet been punctured. The longer I have it the better I like it. It has proven so satisfactory in every respect that I don't see how I could get along without it.

Fowler, Col.

CARRYING HONEY, BUTTER, AND EGGS TO MARKET IN A FORD

BY ALBERT SNELL

In April, 1911, I purchased a four-cylinder 20 h. p. Ford touring car. I bought it for pleasure and for taking honey, butter, eggs, and other farm produce to market. It has proven very satisfactory. It will take the steepest grades "on the high" with five persons in, when other cars have failed. I ran it 2000 miles last season; and although our roads are stony and rough I have paid out nothing for repairs. The tires are good for another season. One gallon of gasoline will run it 20 miles, so it is cheaper than a horse.

I am a veteran of the civil war, 67 years of age, and never ran a car before this one.

Clayton, N. Y.

— ♦ ♦ ♦ — **THE AUTOMOBILE FOR OUT-APIARY USE**

BY J. A. GREEN

That the automobile may be made one of the greatest of time and money savers is becoming daily more apparent. To no one does this apply with more force than to the beekeeper who keeps bees away from home. The ways in which it may be helpful to him have been mentioned so often that it is hardly necessary to go over them again; but, briefly, the most important are these:

J. H. Thomson and family in their Ford, which they drove 2550 miles, and had only one puncture.

J. A. Green and his two-cylinder Reo carrying a load of forty supers.

The great saving in the time of travel. The man who has out-apiaries five, ten, or more miles from home must spend many hours on the road. This time, which may be called non-productive labor, may be shortened to approximately one third by the use of an automobile. The time of a man who is caring for a large number of colonies is very valuable during the busy season, and it is just at this season that the most traveling has to be done. At any season it is very wasteful to spend nearly half of your time in getting to and from your work.

A further great saving of time, labor, and worry is made because of the possibility of entering and leaving an apiary safely at any time of day, and of being able to drive up close to the hives to load or unload. It is wasteful of both time and labor to be obliged to stop your wagon some distance away from the bees, and carry all the supplies from there to the hives, and all the honey from the hives to the wagon, even if a wheelbarrow can be used, which is not always the case. Then there is the never-ending worry lest the horses should be stung in spite of all precautions, resulting, perhaps, in an expensive runaway and breakdown, to say nothing of the risk to life and limb. Many a time I have had to wait until dark before I could safely leave an apiary with my load, not getting home until nine or ten o'clock at night, which is neither pleasant nor profitable. A very successful beekeeper

once said to me, in talking on this point, "I am twenty years older than I was ten years ago." We owe it to ourselves and those dependent on us not to waste our energies by unnecessary work and nervous strain.

I have been using an automobile in out-apiary work for two seasons. My car is a second-hand Reo two cylinder five-passenger touring car which cost me in Denver \$400—somewhat less than a third of the price of the car similarly equipped when new. It had seen some hard service; but, being somewhat of a mechanic, I trusted to be able to keep it in running order. This has taken more time than I have liked, though otherwise the results have been fairly satisfactory. There have been occasions, to be sure, when things did not work quite smoothly, and sometimes these seemed to come at the most inopportune times. For instance, one night when I was coming home with a heavy load of honey the chain broke, twisting up the sprocket somewhat. I repaired the chain a couple of times, getting only a little further each time; and when darkness overtook me I had to telephone home for a team to come and haul me in. Next day Dr. Phillips and Wesley Foster were to be in our town, and I had expected to take them for a ride through our valley. I worked on that car until the last possible minute, and then had to give it up and admit that the thing couldn't be made to run reliably until a new part had been secured. Then

there was Prof. Blinn, the expert on cantaloupes, sugar beets, and alfalfa, whom I was to take on his way of spreading information throughout our farmers' institutes and rural schools. The car had been running beautifully the evening before; but in the morning it wouldn't go, and it continued not to go until I had spent a couple of days of strenuous toil on it. But such things are painful to remember, and I will refrain.

I have been unfortunate in my experiences with having work done in the garages, which I have found both expensive and unsatisfactory. Doubtless this would not be true in all cases. Of course not all have either the training or the equipment needed to do much automobile repairing; but every car-owner should learn as soon as possible to make at least all minor repairs and adjustments himself. A new car should give little or no trouble for a year or two, by which time the owner should be familiar enough with its mechanism to keep it in order with very little assistance.

This model Reo was so made that the tonneau, or back, was readily removed. To do this easily I have two small "safety lifts," or pulleys, with clutch, hanging from the ceiling overhead. These hold the load automatically at any height. One of these on each side is fastened to the ceiling over the car, the hooks engaging in wire loops slipped over the supports of the folded top. With these one man can easily raise the tonneau up out of the way. To put in place of the tonneau I have two backs, one of

which transforms the touring car into a neat runabout; the other into an express or delivery wagon. Without any help I have taken off the touring body and replaced it with the express body in nine minutes.

In getting a car which one expects to use in a commercial way the tonneau should be made so as to be easily removed. With many cars this can not be done. With some, the whole body could be removed, though this would require a much more expensive wagonbox to replace it. In some cars the removal of the body is not practicable. Unless there is some kind of box that will carry at least a small load, one of the most important advantages of the automobile will be missed, as out-apiaries demand a constant stream of supplies, and the greater part of the honey can be hauled back on the return trips, making special trips for that purpose unnecessary. If the automobile is wanted only for transportation, a motor cycle is much cheaper and even more speedy. Of course the motor car can be used also for the transportation of the family.

Get a new car if you can afford it. If you buy a second-hand one, be sure what you are getting. Many second-hand cars are better bargains, so far as actual use and value are concerned, than new ones; but usually they sell for about what they are worth, and there is always some risk in buying an old car. If it were not for this it might be advisable to get an old car for the first season, disposing of it after you had become familiar with motoring.

D. C. Polhemus' new building for a workshop, extracting-house, etc., and his two International auto wagons which he uses to carry the combs to and from the apiaries.

The illustration shows my business wagon with a load of forty supers on. There are generally one or two more grown persons in the touring car, and I have taken as many as thirteen in it, though such overloading is rather hard on tires and the machine in general.

The engine of this car is nominally of twenty horse-power, though figured by the rule generally used it is only eighteen, and at this altitude only fifteen, which is hardly enough for heavy loads on some of our hills unless the engine is working perfectly.

Some details on the construction of the express body may not be amiss. The foundation is made of 2×4's bolted down by the bolts or thumbscrews used to fasten the tonneau, with another pair set near the front end to overcome any tendency to tip down behind. Lugs into which to screw these bolts must be fastened to the frame of the car.

On this foundation is built the box 40½ wide and 56½ long inside, which is just right for eight hives or supers of the eight-frame size, provided there are no cleats nailed above handholes, which are a nuisance whenever hauling is to be done.

The front end of the box must be high enough, and sit back far enough to keep the load from sliding against the backs of the seat in front. The sides, which may be of any convenient height, are braced outside by L-shaped braces, which at the top are formed into hooks turned outward. One of these comes opposite the middle of each row of supers. A waterproof canvas over the top of the load is a protection against dust or rain, and helps hold the load together. A light rope, hooked back and forth through the side hooks, and tied in a single knot, holds all securely, yet may be removed in a few seconds. While an automobile may bounce considerably, it is not so hard on a

load, and especially does not shake it from side to side as badly as the ordinary vehicle.

Being an orchardist as well as a beekeeper I am obliged to keep horses. An electric railroad also runs close to my home and to my out-apiaries. I do not use either of these ways of traveling much in summer, but I consider the automobile practically indispensable.

Grand Junction, Colo.

AUTOMOBILES USED BY A 2000-COLONY BEE-KEEPER

Combs Hauled to a Central Extracting House in International Auto Wagons

BY D. C. POLHEMUS

The accompanying picture shows our auto wagons, one of which has been used three years and the other two. They are "Internationals," and they have been in use constantly from April to November each year, in going to and from our fourteen bee yards scattered over the county at a distance of from three to twenty miles from home. We have headquarters here in Lamar, where we do all the work such as putting in foundation, repairing supers and hives, and other work that is not necessary to be done at the yards. On our daily trips this ready-to-use material is taken to the apiaries.

Of course we do not make very long runs. This style of machine is not intended for fast running, like a pleasure car; but we make an average of twelve miles an hour on our trips to and from the yards, and carry from fourteen to eighteen full-depth extracting supers of honey. We have hauled at one time as many as 36 supers of empty combs.

Before getting a machine I felt that it would give us considerable trouble, especially as some of our yards are in irrigated fields, and some on sandy knolls. The roads are sandy some of the way, for we located the yards before we had the autos, and we picked out all kinds of out-of-the-way places. We are more careful now where we locate an apiary, for it does not pay to locate where we know we shall have hills, sand, and frequently mud to bother us every week of the season whether we use an auto or team and wagon.

We have had very little trouble with these machines. We go almost anywhere that one can with a horse

Ready for a quick run through mud or sand.

Interior of the extracting room, showing eight-frame extractor driven by electric motor.

and wagon, for, being of the high-wheeled type, and having solid tires, mud does not stop us unless it is very deep. We have not put on any new tires yet; but the three-year-old machine must have new tires on the rear wheels before we begin another season's work. A local blacksmith has bought a machine for putting on tires, and offers to put on two rear tires for \$35.00.

It costs about two cents a mile for gasoline and oil. We think the expense of keeping a machine is no more than keeping up a team, wagon, and harness, to say nothing of the satisfaction one gets out of the machine in the yard, and the time saved on the road. We would not try to get along without an auto for our work.

One of the main features of planning our work is to get the most out of the boys' time during vacation, and get as nearly finished up in the fall by time school commences as possible. We have thought of a heavier machine—one that would carry more honey—but have finally concluded that, as we have more or less sandy roads, and occasionally mud to go through, a medium-weight machine is better.

The International machine costs \$800, so we can use two machines and have no more money invested than if we had one of the larger style of motor wagons or trucks. We are not prejudiced in favor of the International, but have looked over other makes, and think that, for our work, it is the best we have seen. There are a good many days

in the year when we have very little if any load to carry, and this is something to consider; for, instead of having to run a lot of extra machinery over the country, we have a speedy and economical way of traveling.

We kept two teams before we got a machine, and still keep one, as we have some heavy hauling to do at times. Each of the machines will carry a thousand pounds; and as we go to some yard every day we get our honey in as fast as one man can extract it.

For several years our extracting was done at the outyards, and the honey run into five-gallon cans and hauled home every day. This plan has some advantages; but the cost in time and labor of keeping up a house at each yard, and moving the extracting outfit about twice a week, and seeing that the wants of a force of men are supplied, induced us to try a different plan.

The last four seasons we have been hauling all the honey home, where we have an eight-frame extractor run by an electric motor, which we think is the best power for running an extractor. Some may think this entails too much hauling of honey and supers; but we find we can take care of more bees with the same help, and do not need so many supers, as we keep extracting every day, which gives us a supply to take out to the yards each morning during the extracting season.

I might say a little in regard to our apiary work. We use both the eight and the ten frame hives; and while I have some prefer-

One of D. C. Polhemus' out-apiaries near Lamar, Colorado.

ence for the ten-frame I don't think there is any difference so far as results are concerned. We can give as much room in an eight-frame hive as any colony needs by piling up supers, and the eight-frame is lighter to handle.

We winter most of our eight-frame colonies in two stories. Of course this means such colonies as we run for extracted honey. The comb-honey colonies are wintered in one-story hives.

All our bees except one yard are run for extracted honey. This may be a mistake considering the demand for comb honey this year; but we have thought for some time we would quit the production of comb honey altogether. I like the comb-honey work myself, but it is difficult to get help that is satisfactory.

Our bees are all wintered out of doors, packed to protect them from bad weather. Some winters the packing is not necessary; but this winter, when we had a month of zero weather, the packing saved many colonies from freezing.

We unpack about the middle of April, and examine each colony to know about their stores, but disturb the bees as little as possible till the weather warms up good about the first of May. In this climate the nights are very cool till late in the season, and it is a disadvantage to try to work them too early. When the strongest colonies have their hives about full of brood we equalize, giving each of the weaker ones a frame of sealed brood.

We used to tier up the hives, and not extract much till the end of the season; but with our present method our hives never

get more than three stories high, and many of them only two.

Lamar, Colo.

THE "CADILLAC THIRTY" FOR BUSINESS AND PLEASURE

BY LOUIS C. KOEHLER

In June, 1910, I bought a "Cadillac Thirty" motor car. It is a four-passenger car with removable tonneau. I made a box with a roof which is put in place of the tonneau when I go to market. It has a door in the back, and will hold 500 pounds of honey besides sundry other articles.

My two main honey markets, Manitowoc and Two Rivers, are twenty and fifteen miles respectively from the apiary. Formerly it took me two days to go to Manitowoc, sell the honey, and return, wasting eight hours on the road. Now I can go to Manitowoc in one hour, sell the honey, and return before dark. I find the automobile very convenient in delivering honey. I do not have to bother with tying the horses, having them shy at other automobiles, and I have no bother and waste of time in feeding at noon.

In fifteen minutes I can replace the tonneau and then have a pleasure car. Besides using the car for the honey market and pleasure, I find it a great convenience during the busy season if I must go to some distant place rapidly.

My expenses for repairs have thus far amounted to ten cents, for welding the brake-connecting rod. I still have my original set of tires.

Mishicot, Wis.

COST OF RUNNING A SIX-YEAR-OLD REO

BY E. J. ADKISSON

I have a Reo two-cylinder touring car of 20 horse power. It has seats for five passengers, but the rear seat is removable by loosening two thumb-nuts. A "wagon box" can be quickly put on its stead. The box is 38 inches wide, 48 long, and 30 deep. It was made especially for hauling bees, hives, supers, and other things pertaining to bee-keeping; but we find that it has many other uses. We use it for carrying any kind of light freight up to four or five hundred pounds. Freight shipments of supplies from the depot, twelve miles distant, and pigs from a neighbor's place four or five miles away, may be mentioned as having been carried by auto in that box. It will hold twelve hives of bees without crowding; but when bees are moved in this manner, both slow and careful driving are necessary. The machine however will not "run away," no matter how many angry bees are flying and stinging. I can hardly say as much for the "shofer," however.

We have used the old Reo for many business and pleasure trips to Nashville. While the car is far from being up to date in appearance, it has a good motor, pulling up the hills very nicely, and gives as much speed on the level as the condition of our roads will allow. There are usually only two passengers, in which case the tonneau is replaced by a covered box or deck. The box is ten inches deep at the front, sloping to eight inches at the rear. It covers the whole tonneau space, 35x35 inches. It is fitted with a removable top or lid, having lock and key. We find this box a great convenience in carrying small wares such as eggs, butter, extracted honey, etc., to market, and bringing home small purchases from Nashville and West Nashville. This old car has been in use six seasons, and is still in good condition and in good running order. The upkeep expense to 1910 was about \$50 or \$55 per year. Of course, this does not include the cost of gasoline and lubricating oil, but does include every thing else—even the tire expense.

In 1910 I had to have a new transmission and water-tank put in, and also bought four Kimball steel tire-cases, a driving chain, one new tire, four inner tubes, tire-holder irons, horn bulb, tire-cover, tire-liners, tire-repair outfit, etc., amounting all together, including repairmen's and vulcanizer's charges, to about \$200.

For 1911 my expenses, outside of gasoline, grease, oil, and dry batteries, were practically nothing.

THE TIRE PROBLEM.

For 1912 the upkeep expense should be very light, as I do practically all of my adjusting and minor repairing. Two things of value that I have learned are that, with acid and cement properly used, an inner tube repair can be made that will hold as long as the tube lasts, and that a few drops

of sulphuric ether on a sponge placed in the carburetor intake will cause a motor to start on the coldest morning with very little cranking. I have taken an old tire, three or four years old, apparently rotten and worthless, having suffered a blow-out and rim-cutting; had the blow-out vulcanized, put in an interlock inner tire around the tube, a Kimball steel case over the outside, and have run it for fifteen hundred miles without puncture or blowout. New tires at that time were selling at a frightfully high price. Considering the prices at which good tires can now be bought, it probably does not pay to bother with old tires after they once blow out. For some time there has been a discussion in the columns of *Motor Age* as to whether or not it pays to have tires retreaded and blow-outs vulcanized. The general consensus of opinion seems to be that the same amount of money invested in the purchase of new tires is more satisfactory than having old tires repaired. Of course, there are exceptions. One is that of a new tire, or at any rate a good one, that has been cut by running over a broken bottle. Such a tire should certainly be repaired. It all depends upon the condition of the fabric of the tire and the skill of the repairer. A poor job of vulcanizing will ruin a good tire, while the utmost skill in vulcanizing can not restore a fabric that is rotten or worn out. It pays *big* to keep the small cuts in the tread rubber repaired, so that water, sand, and mud can not reach the fabric. There are various compounds sold for filling such cuts; but it is probably best to use one of the small vulcanizers which are made especially for such work and for repairing inner tubes.

A friend of mine, a commercial traveler, is using, on his Hupmobile runabout, clincher tires 30x3 inches, for which he pays \$10.60 each. He is going all the time, making from 25 to 125 miles a day, and states that these "cheap" tires are giving him a mileage of about eight thousand miles per set. He is a great believer in hard-pumped tires, keeping them inflated to even a few more pounds pressure than is usually recommended for tires of that size.

FRICTION TRANSMISSION BETTER THAN GEARS.

I am a regular subscriber to and reader of two of the leading automobile magazines; and the more I learn about motor cars, the more I am convinced that a car having a friction transmission is more satisfactory than one having a gearbox and clutch. It is generally known that the change-speed gears, the clutch, and the propeller shaft with its connections, such as bevel gears, universal joints, bearings, etc., are a frequent source of trouble—especially if these parts have had considerable use and are pretty well worn. A breakdown involving any of these parts is likely to occur far from home, and with little or no advance warning. The car must be "towed in" to the repair shop. Expensive new parts must be ordered from a factory which usually fills

Harley-Davidson motor cycle, used for carrying a load.

orders for such parts in a very leisurely manner, while you are losing the use of your car. None but an expert repair man should attempt to replace and to adjust such new parts.

In the usual course of events, however, the car is literally "torn to pieces" by young "cubs" who hardly know a monkey-wrench from a mouth-organ. When the time for reassembly arrives, a more or less skilled repair man tries to undo some of the harm the "cubs" have done. Such proceedings are not good for a car's health, to say the least. A well-designed and properly constructed friction transmission practically eliminates the troubles mentioned. It is easier to learn to operate than sliding gears, gives any number of speeds, is noiseless, does not break down suddenly, and repairs are inexpensive. The only part subject to much wear is the fiber facing on the cross-shaft wheel. It simply *wears* out slowly, giving ample notice, so that a new fiber ring can be kept ready to replace the old one when it becomes necessary. The services of an expert mechanic are not required, as almost any one can put in a new fiber ring in two or three hours' time, and the cost is about \$3.00. One of my friends had a fine 1910 Cadillac. Some of his transmission gears stripped off, and the repairs cost him \$40.00. The transmission of my old Reo "busted," and the cost to me was about \$65.00. Compare these expensive and troublesome repairs with the cost of a new fiber for a friction transmission. It may make you decide, as I have, that my new car must have a friction drive.

The leading makes of friction-driven pleasure cars are the Cartcar and the Lambert. Others are the Lincoln, Sears,

Petrel, Metz, Dispatch, Kearns, Duryea, and Rogers. So far as I can determine, the Lincoln and Sears are exactly the same car under different names at different prices.

Nashville, Tenn.

MOTOR CYCLE USED GOING TO OUT-APIARIES

BY W. F. DUNLAP

I am sending you a picture of a gentleman who, because of eye trouble, is unfit for many kinds of work. He has entered enthusiastically, and I might add successfully, into beekeeping. He is shown in the picture about to start for one of his outlying apiaries, on his motor cycle.

Milwaukee, Wis.

TROUBLE WITH THE SEARS

BY WM. MUTH-RASMUSSEN

During the 18 months that I have had my Sears machine it has been out of order nearly all the time, and I have been practically a prisoner at home. This car may do very well on city streets and on good hard roads; but with narrow solid tires it is entirely unsuited to sandy and soft country roads. I finally had to get a set of new wheels with pneumatic tires, for which Sears, Roebuck & Co. charged me \$170.00—just double the difference between the price of a car with solid and one with pneumatic tires, although I labored with them about the unreasonable-ness of this exorbitant price.

As soon as the new wheels arrived, two of the tires were leaking. When I reported this, Sears, Roebuck & Co. sent me two new

inner tubes; but these too have been leaking, and I have had no use of the machine, to speak of, as there has been trouble every time I had it out.

The new wheels cost me, freight and all, over \$200. The old wheels are useless to me; but if returned they would barely pay for the freight charges, as I have ascertained. I have spent over \$800 on the machine, and it has been nothing but trouble and vexation to me so far. There is no prospect of selling it here, and it would not pay to send it to San Francisco. If I had a spare building in which to store it I would have bought a new horse long ago, as I used to keep one; but I put a wooden floor in my stable for my auto, which is now occupying that building, and I can not afford to throw it out on the scrap-pile.

Independence, Inyo Co., Cal.

[I am sorry to get such a letter as the above; but it would be manifestly unfair to give our readers the impression that running an automobile is all fair sailing. I have had some years' experience with autos, and our family have owned and have run a number of different makes of cars, and I must say the Sears car has given me more service and more satisfaction than any other I ever got hold of.

In regard to the solid-rubber tire, when I ordered my machine I thought solid tires would be best for the Florida sand; but the company wrote me at once that they were sure the pneumatic tires would be much better; but a brother in Michigan bought a solid-tire machine, and he and I rode many miles through sand and through mud, right after a rain, and over rocky roads, without any trouble whatever. He has since run it on long trips over the desert between Phoenix and Pima, in Arizona, and, I think, with very little trouble except that he had to wait for his new friction filler, which he should have ordered in advance.

Now a word about inner tubes. We can not order these in advance and keep them in stock; for I am told that, especially here in this warm region, they last only about a year before they get rotten, or something like it. When I ordered my machine I also got an extra tube to be held in reserve; but this tube that wasn't used at all seemed to go to

pieces about as soon as the others. Well, if this is true (but I *hope* it isn't) suppose a dealer tries to keep a stock on hand (to fill "emergency" orders), if he should happen to keep a tube a year it might give no service at all, even if it was brand-new. Three of my four tubes began to give trouble in just about a year, and yet I had the very best make in the market. In the above case the company furnished two new inner tubes without cost, and yet it may not have been any fault of their own. Of course, I do not know just what kind of roads our good friend Muth-Rasmussen has in his neighborhood; but my impression is, if he will be patient and gradually learn to make needed repairs himself he will yet get not only much service, but much enjoyment out of his machine. This will have to be done, more or less, with the best machine made, no matter what it cost.

Permit me to mention, in closing, that Sears, Roebuck & Co. have just sent out the finest and plainest instruction book for their car I have ever seen for any automobile. It is profusely illustrated, and made so plain with arrows and numbers that any ordinary mechanic, with such a help, should be able to make his own repairs. Yes, it does usually cost something to keep an auto in repair; but it costs nothing when idle, which is not true of a horse.—A. I. ROOT.]

THE SEARS FRICTION-DRIVE TRUCK

BY GRANT ANDERSON

I have used an automobile for visiting my out-apiaries and for hauling light loads for several years, and would not think of doing without one. Several of my apiaries

If a box is properly strapped or tied to the luggage-carrier, quite a load may be carried successfully on a motor cycle.

are between ten and fifteen miles from home; and to drive that distance with a horse is tiresome and a waste of time. Then when a visit has been delayed from some cause, which will happen sometimes, and one finds several swarms out when he reaches the apiary he can hop out of the car and begin to hive swarms; but if he has a horse he must look after it first, to say nothing of the hour or hours lost on the road in getting there and the same in getting back or to the next yard. With an automobile I can reach any of my apiaries in less than an hour, and can work till dark if necessary, and run home by lamplight.

The first auto I bought was a Holzman, with high wheels and solid tires. This car has a long body and a removable rear seat. With this seat removed I have room for a lot of hives, camp outfit, or a lot of baby nuclei. This car has done good work for five years, and is in good condition yet, except the front axle, which was broken yesterday in a collision with a runaway mule team in the streets of San Benito.

I have another car that I bought from Sears, Roebuck & Co., Chicago. This car is a light truck with a long body and droptail gate. The wheels are 36 inches high, with solid tires. While I have not had it long, I am well pleased with it, and believe it will be a great help in hauling bees, honey, and other goods, as I can dispense with the horse and wagon to a marked degree. This little car was not built for speed, but it makes as much time, when not loaded, as I care for.

I believe this to be one of the best and handiest autos for beekeepers that is on the market to-day, and the price (\$375) is within the reach of all. I would advise everybody, before purchasing an auto, to write Sears, Roebuck & Co. for an auto catalog; also to The Chilton Printing Co. for a copy of *Cycle and Automobile Trade Journal*, Market and 49th St., Philadelphia, Pa. In that journal many makes of automobiles are advertised. I believe all the leading bee-men in Texas have an automobile. San Benito, a town less than four years old, has over one hundred automobiles in town and on adjoining farms.

Brother bee-man, get you an auto and add ten years to your life and many dollars to your bank account.

San Benito, Texas.

THE AIR-COOLED AUTOMOBILE PREFERRED

BY LOUIS WERNER

The first automobile that I owned was a 7 h. p. Brush runabout, equipped with a water-cooled one cylinder motor. I ran it one year; but it was too small, and lacked power. I also had a good deal of trouble with the radiator, as it kept leaking; and other things got out of order, so that I sold it last fall and bought a new machine—a 14 h. p. air-cooled Kenmore. This car is equipped with solid tires, and I can use it for delivery

purposes or for pleasure. By adding another seat it will carry four persons.

The cost of upkeep I have found to be very small, the only expense I had during the first six months being 75 cts. for a muffler. I have no tire trouble, and there is no radiator to leak. I find I can run this car for \$2.50 per month, including every thing. A horse would cost me \$10.00 to \$15.00 per month, whether used or not. The car costs \$500, and it is the best investment a bee-man can make.

This machine is well built, is strong and neat, and is very easy to run, so that I think it is an ideal machine for a beekeeper who has an outyard. It can be driven right in among the bees, and there is no danger of any horses being stung. I am in favor of an automobile every time, instead of horses, around bees.

Edwardsville, Ill.

WHY I BOUGHT AN AUTOMOBILE

BY P. H. BALES

I have 670 colonies of bees, located in ten apiaries from five to twenty-four miles from home. With the machine I can go to the furthest apiary, do a day's work, and return the same day.

European foul brood broke out among our bees, and they required so much care that I needed to be at several apiaries the same day. I bought the machine thinking I could give my bees so much better care that they would make enough more honey to pay for the machine, and I think they have done it—and the fun!

WHY I BOUGHT A MITCHELL

My machine is a four-cylinder, 1910 model, five-passenger Mitchell "30." I paid \$1750 for it two years ago. I bought this machine, because I thought it would give the best service for the money, and I think (after two years of use) I made no mistake.

I have driven 13,000 miles, and have discarded only one tire casing. The repairs have been practically nothing.

For hauling supplies I have an extra body that takes the place of the back seat. I have moved 260 colonies of bees this winter, 14 at a load, with extra supers on.

My machine failed just once to go, and I was seven miles in the country. I telephoned for the machinist to come and haul me in. He came out and threw off the emergency break, and said, "Now you are all right," and so I have been ever since.

My advice to prospective buyers is to use the same judgment in buying a machine as in buying a horse. The one that costs the least is not always the cheapest in the long run; and if the machine is being sold with a 3½-inch tire, have a four-inch put on instead. It will be money well spent.

Hanford, Cal.

USEFUL HINTS FOR THE PROSPECTIVE PURCHASER OF AN AUTOMOBILE.

BY CYRIL BRODNIX.

From my ten years' experience with gasoline engines and automobiles of some twenty-five or thirty different makes, I find that one of the most misunderstood points is the question of horse-power. The Society of Automobile Engineers' (S. A. E.) rule for obtaining horse-power is to multiply the square of the diameter of the cylinder by the number of cylinders, and divide by 2.5. The number of revolutions per minute, and the length of stroke of the piston, are not counted, although each has something to do with the actual horse-power that the engine is capable of developing. This rule, therefore, is only approximate.

An engine that will develop 15 to 20 horse-power is usually sufficient for a machine seating two or three people; and one that will develop 20 to 32 horse-power for one seating four or five people. A larger engine costs more to operate, and nothing is gained; for twenty-five to thirty miles per hour is as fast as it is safe to drive on country roads, and this speed may be easily maintained with the sizes of engines given.

The single-cylinder machine is the simplest, most economical, and the lowest in first cost; but single-cylinder motors are limited to 10 or 12 horse-power on account of the difficulty of cooling the piston if a larger cylinder is employed. The two-cylinder engine has some advantages over the single cylinder; but the four-cylinder engine is usually considered to give the best service on account of its more uniform power and comparative lack of vibration. The six-cylinder engine gives still steadier power, and has almost no vibration; but it is more complicated, more expensive, and much heavier than a four-cylinder engine of equal power, and for this reason it is very seldom used on cars selling at a medium price. The water-cooled four-cylinder engine, therefore, of the four-cycle type, located under the hood, gives the best service in medium-sized cars.

The engine should be so placed in the frame as to be easily reached for cleaning, adjusting, and repairing. It is a good thing if the crank case has handhole plates on the side to permit adjusting the crank pin or main bearings without having to remove the under half of the case.

The valves in the cylinder head should be of ample size, and located so as to permit

easy cleaning and grinding. The valve stems should have ample guides to keep them in line, and should be protected by some kind of housing or cover plate to keep out the dust and dirt, and also to muffle the noise.

If a water-pump is used it should be located so that the packing may be easily renewed.

The magneto should be in such a position that the contact point and connection may be easily inspected and tightened.

The carbureter should be set high enough in relation to the frame so that the gasoline feed-pipe may be readily disconnected for cleaning.

The oiling system should be capable of delivering plenty of oil to all moving parts all the time. Such parts as the pistons, wrist pins, crank pins, crank shaft, the half-time gears, cam shaft, cam-push rod, and valve stems should be automatically oiled. There should be rollers on the cam end of the valve-push rods.

The three-speed forward and reverse selective sliding-gear transmission is the one most used, and the one to be preferred on account of its positive action, long life, and freedom from trouble.

The clutch that gives the least trouble is the one that is the simplest and that has the fewest parts. The cone clutch having an asbestos fiber face is usually to be recommended on this account. A leather face is all right, although it is more likely to burn if the clutch slips.

The universal joints of the shaft drive should be so made that they run in oil, thereby reducing their tendency to cut.

The rear axle to be recommended is of the full floating type; that is, one in which the weight of the car does not come on the shafts that drive the wheels. The best rear axles are equipped with Timken roller bearings throughout.

There should be two sets of brakes acting independently of each other, acting on the drum attached to the rear wheels. The one set should be internal, expanding metal to metal, and the other external contracting, the band having an asbestos lining. The external brake should be used for service, and the internal for emergency. The objection to a brake on the driving shaft is that it sets up undue strain and jars on the differential and the rear-axle assembly in general.

Before buying a car it would be well to ask the dealer the following questions:

How many miles per gallon of gasoline and oil will the car travel?

Are the valve stems and springs of the motor protected from dust?

Is the water-pump easily repacked?

Are the magneto and carbureter accessible?

Will the clutch act smoothly without sticking or slipping?

Is the transmission case accessible?

Is the rear axle strong enough?

Thorpe, Washington.

BUZZINGS ROUSED BY THE MARCH 1ST ISSUE

BY ALLAN LATHAM

It is but natural that an unexpected article such as "A Contrary Beekeeper," March 1, page 133, should stir said beekeeper out of lethargy. Months have passed since Latham has written any thing for publication, his many irons in the fire occupying all his attention. There have been many times when he wanted to get up and speak, but failed because of insufficient stimuli. Large entrances, hard winters, paper protection, etc., as brought to the front March 1, together with that article of Miller's, are too strong, so here goes.

What the editor has to say about wind, protection, and cold spells is all good sound sense, even if he is a little off about inside temperatures. Wind is the great enemy of bees in winter, and no small antagonist in summer. Unless the hive be fitted with air-tight cover, with no chance for a draft, it would be folly to subject a colony to the rigorous trial which a cold wind will put upon it. Still air at zero is less of a hardship for a colony than a gale with the temperature 30 degrees higher. Large entrances so placed as to let a steady blast of cold air in upon the cluster will bring disaster. That same entrance so placed as to receive only winds of moderate temperature or deflected cold winds will tell a different tale.

Steady cold? Yes, that is what kills lots of colonies. The contracted cluster consumes all the fuel within reach, and starves. How combat such a foe? Fortunately, steady cold is rarely accompanied by sunless skies for many days at a time. So, let the sun break up the continuity of that steady cold. Here is where the big entrance and the black paper do the work. The black paper catches the heat and passes it slowly through the walls of the hive, and stirs up that contracted cluster. New fuel is brought in from the stores near by. The weary insects stretch their limbs and take new courage. The big entrance carries away the dampness, and the cold is less deadening. Night comes with the steady cold again ascendant, but the little furnaces are going full blast with plenty of oxygen to furnish good clean burning. What satisfaction to see the vigor and clean health of those same bees when April comes!

True, there is much in locality. I have found it true even with "let-alones," and there is one place down on Cape Cod where I have had to cut down those big entrances. Why? Because a long stretch of sand allows the damp ocean breezes to sweep unobstructed right into those hives. This present winter I have again left them wide open to put the matter to a further test. The severe winter will give a faithful test.

Yes, it is a severe winter here; but, though Norwich is but 50 miles from Providence, where Miller lives, this winter does not compare in severity in Norwich with the winter of 1903. That winter no flight came to the

bees from Nov. 19 till March 22. It was stated that 75 per cent of bees along the New England coast perished that winter. This present winter will see the end of many colonies, but only of those not properly supplied with stores or those weak in bees. My own colonies at present date (March 8) are in splendid condition, having enjoyed flights in December, January, and February, each month furnishing an ideal day for a cleansing flight.

Mr. Miller has painted a very rosy picture of the let-alone hive. Be it known that there are troubles with these let-alones which are peculiar to them. This system of beekeeping has its fine features, and teems with interest; but it furnishes no quick road to wealth, nor need a lazy man look upon it with too optimistic a gaze.

Norwichtown, Conn.

PUTTING BEES ON THE SUMMER STANDS

BY B. H. TRIPP

With the first warm days of spring comes the desire to get the bees out on their summer stands. Oh how one longs to watch the busy little workers hustling with their duties for the good of the colonies! But it will not do to be in too much of a hurry, for there will be many days when they will be better off in the cellar or cave than outside, huddled together so closely as to chill the outer brood or eggs.

My 28 colonies are in a cave 6×8 feet square. I have been down to see them but once since Jan. 1, and have just put some rubber roofing over the snow that covers the hatchway, in order to keep it from melting as long as I can. My object is to keep them as nearly dormant as possible until there is something for them to bring in.

When the snow is all gone, and fair weather comes, I shall keep my weather eye open for a cool spell, when the bees will not fly for a couple of days; then I'll open the doors about sundown and leave them for two hours to cool off. Then, after placing a wet cloth over the entrance, I will gently carry them out and place them on their summer stands.

By way of assistance to them in their housecleaning, I will (on the first warm day) place them on fresh clean bottom-boards. This, I think, is important, as it saves a lot of hard work removing the dead bees and cappings that have accumulated during the winter.

As this stuff is more or less damp, it is a sanitary precaution to remove it as soon as possible. At the same time I will remove the empty or moldy combs and shove the remaining combs and followers to the left side of the hive. My followers are always on the right side, as my hives face the south. I think that they afford some protection against the cold west winds of spring, and, after, from the hot afternoon sun.

Brooklyn, Iowa.

Heads of Grain from Different Fields

Solid vs. Pneumatic Tires ; Friction Transmission

I should be pleased to know the respective advantages of solid tires and pneumatic tires, taking into consideration the question of cost. Is there any particular advantage in the friction transmission? For utility, would something like the International auto wagon be better than an ordinary car with trailer?

Wesley, Ont.

GEORGE WOOD.

[On practically all of the motor trucks and wagons used and manufactured in this country, solid tires have been found to give the best satisfaction. They are not adapted, however, to speeds above fifteen miles an hour; but since this is plenty fast enough for a machine carrying a load, it is evident that the high wheels and solid tires are much to be preferred to the pneumatics for the light trucks and wagons used by beekeepers. The hard tires will ordinarily wear about two years, although the character of the road has a great deal to do with the question, since rough stony roads grind away the rubber much faster than clay, sand, or even gravel roads. Pneumatic tires, if used on a truck, would not last as long as this. They would cost much more in the first place; they would require expensive repairs continually, and there would be many delays when time is worth money. As the commercial vehicles are used more and more by all classes of business men instead of horse-drawn delivery-wagons, etc., blacksmiths over the country will gradually put in a machine for re-tiring the wheels. A great many blacksmiths (in the larger towns at least) are already equipped for putting rubber tires on buggy-wheels.

Of all the different kinds of transmission or devices for changing speed, the friction transmission is the simplest, the cheapest to maintain, the most trouble-proof, and the easiest to operate. Among the disadvantages may be mentioned the fact that the friction transmission, if properly designed, costs more than a sliding gear, for instance, and it is slightly less efficient on low speeds especially. However, this loss of efficiency is far less than many imagine, which fact is shown by the increasing popularity of this form of drive for light trucks and commercial vehicles of all kinds. Personally we are quite in favor of the friction transmission.

Regarding the use of a trailer, we will say that, for some reason or other, this has not proven very practical. We noticed an account not long ago of a piano dealer, however, who was moving pianos very successfully on a trailer, which may possibly indicate that one reason why trailers are not used more is that there has been so little experimenting done along this line. Mr. F. B. Cavanagh, of Hebron, Ind., uses a two-wheel trailer, as illustrated on p. 500 of the August 15th issue, 1911. His trailer, however, is pretty hard on the rear tires of the auto; for, in addition to standing the wear and tear of attraction, they have to hold the weight of a good share of the load. It may be, moreover, that the bearings, which are not designed for such a heavy load, will give out. A four-wheel trailer would overcome this objection; but at the same time such an arrangement is rather hard to manage in turning corners, etc. We presume that the most economical way is to use a commercial vehicle designed for carrying a load, in order to avoid these complications.—Ed.]

500 lbs. of Comb Honey Carried in a Ford

I did not purchase my automobile for the express purpose of using it in connection with the apiary, but more as a pleasure vehicle for the family; but I find there are many uses to which it can be profitably applied in connection with the apiary, especially in marketing the crop, if sold to consumers or grocers.

My machine is a five-passenger Ford; and, although designed especially for a pleasure car, I have marketed all my honey the past two seasons with the best of satisfaction to myself and to my customers.

I can carry four or five hundred pounds of comb honey each trip, and the honey is delivered in the best condition, crates all clean and fresh, and not a broken section at any time to mar the appearance and sale. The beekeeper does all the handling himself, and handles it as it should be, thus insur-

ing first-class delivery. Besides, it is cheaper than freight or express, all things considered. I have also transported bees, hives, queens, and supplies to some extent; and I find that an automobile adapted to the purpose can be made a useful and profitable adjunct to all kinds of apian transportation, and a great source of enjoyment in making business and pleasure trips.

Athens, O.

J. C. ATKINSON.

Moving Bees in Record Time with a Buick Truck

On a November morning, with the mercury at 40 degrees Fahrenheit, with twenty handy screens to close hives, and twines ready cut to wrap each end of a hive, a start was made at 6:30 from the city for bee-moving four miles in the country. The necessary work of closing hives and tying was carefully done, 20 hives loaded, and moved three miles to a purchaser's location, and the return made to the city, ready for our delivery work at the grocery, at 8:45. What about this for a good record with a two-ton Buick truck?

Thirty-four hives of bees at a load were hauled one July night a distance of six miles in this same auto truck from one side of our city to new pastures. These bees were all prepared at sundown; loaded, moved, and placed, and the return home was made by 12:30 P.M. We have solid tires. The pneumatic are easier.

I have a 1912 Cole car; one brother has a Reo; another brother an E. M. F., and my father wants a Cadillac.

Evansville, Ind.

W. W. VICKERY.

Is the Friction Transmission Reliable?

I am thinking of buying an automobile the coming season, and I should like to get your opinion of the Cartercar. Do you think the friction transmission and chain drive are what the manufacturers claim? I want a machine that I can depend upon to go through sand and mud, and over the hills. I should like the best there is in a medium-priced car. There are no Cartercars around here, and I have never seen one; but I have their literature, and am very favorably impressed by it; but I should like to learn from good good authority whether they are thoroughly reliable.

Scottville, Mich.

L. D. ALLEN.

[We have driven a Cartercar for nearly three years, and so have had a good opportunity to judge of the merits of this particular car. It is not as low in price as some of the other machines of the same size, but we do not believe there is another car on the market so economical in upkeep. It is almost impossible to abuse the machine; and it will stand hard continuous pulling with the friction-wheel set close to the center of the disk—low-speed position—without wearing out any thing nor doing any damage whatever. Furthermore, the changes in speed may be made at random, from low to high or high to low, regardless of engine speed, and while the car is running in either direction. We have no hesitation in recommending it as the easiest car to drive of any that have come to our notice.—Ed.]

The Ford Contemplated

I want an automobile that I can run every day to my outyards, and one on which the upkeep cost is not too high. Do you think that the Ford could be run a good deal cheaper than the 30 h. p. class, E. M. F., Buick, or Overland? Do you think the Flanders is a better car than the Ford? The Ford was used here last summer; but it has not been here long enough for me to judge much about it. I run five outyards, and want a car that will be the least trouble to look after, and the cheapest to keep up. It must also be rather small to be handled around the yards easily.

Spanish Fork, Utah.

THOMAS J. STANTON.

[There are several Ford automobiles in this vicinity; and our opinion is that, for a light pleasure car, this is the best proposition on the market, for the money. The E. M. F., Buick, Overland, etc., are all much heavier cars, and consequently larger and more expensive tires are needed. Some have thought the Ford too light for strength; but those around here seem to be giving very little trouble.

There is really little risk in buying a machine that has been on the market for a year or two, from any of the old companies that have been in the business long enough to understand the construction of a car. We would not buy a new model just brought out by any concern, for it takes at least a year for the mistakes in design in a new machine to be corrected by the tests made in service.—ED.]

Cement Track for the Auto Instead of a Driveway

My occupation is that of deputy examiner (deputy collector and inspector). Our examinations being made at the factories, I bought a third-hand auto to enable me to get to the different points, which are sometimes four miles apart, in a short space of time. I find that I save about two hours a day in this way.

I used to have a good deal of trouble in the spring from the auto wheels cutting ruts in the lawn nearly a foot deep as it came up the steep grade in front. So I dug two parallel ditches, 56 in. apart from center to center, and put in cement tracks 8 in. wide and 6 deep, with a half-round groove in each, 4 in. wide and 2 deep. I laid a galvanized wire cable in the center of each track to reinforce the cement. This arrangement fully meets my expectations; for when the wheels are once in the groove it would be hard to get them out, even if I desired to. When running in I can hit the grooves every time at a ten-mile speed; and in backing out I merely have to be careful to get the hind wheels started right, and then the front wheels are almost sure to enter the grooves themselves. As soon as all four wheels are on the track I can let go of the steering wheel, as the grooves attend to the guiding.

Bridgeport, Ct. S. J. GRIFFIN.

Mitchell Runs 50,000 Miles

In June, 1909, I purchased a 20-25 h. p. Mitchell car, and it has been in constant use since then. In all, it ran over 50,000 miles, and is still in good repair. My expense for extras has been less than \$100, while my tire expense has been about what any other car would average under the same circumstances. I had never had any experience with an auto or other machinery; but I have been able to handle my car to my entire satisfaction. I would not be without a car, and am aiming to purchase another Mitchell this spring, as they will do the work under all circumstances.

Belgrade, Mont. J. M. GRAYBEAL, M. D.

International Auto Wagon a Time-saver

Last spring I bought an International auto wagon which I have been using since, and find it perfectly satisfactory. As a time and labor saver alone the machine is worth its cost; and, besides, I never have to worry about bees making it break loose and run away.

To-day a hunter brought in the report that one of my houses at an outyard $3\frac{1}{2}$ miles away was open. In forty minutes afterward I had been out, looked after things, returned, and put my car up. How does that compare with harnessing a team?

Rocky Ford, Col. A. S. PARSON.

Auto-repair Man Advises the Cartercar

At present I have about 150 colonies of bees, so I have a great deal of time in the fall and spring to work at my trade—that of repairing automobiles.

Just recently I examined the driving chain in a Cartercar which had been driven 25,000 miles, and neither the chain nor the sprockets show any appreciable wear. Nearly all cars with sliding-gear transmissions and driving pinions must have several replacements before they have been driven that far.

The Cartercar costs more money than some of the others; but it is the cheapest one to buy in the long run. It has one of the best engines that can be built, which gives ample power to handle the car with ease as slow or as fast as one wishes to go. The ignition is all right, and will require practically no attention. I have seen these cars driven 2500 miles without having the engine touched.

This car has the friction transmission. It would be impossible to produce any thing simpler, more efficient, or more economical in the way of automobile transmission. There are any number of speeds which are brought into use with the greatest simplicity. This construction does away with

universal joints, driving shaft, the inefficient troublesome cone clutch, and also the possibility of spinning the tires on the ground with the car standing still. This increases the service of the tires a great deal over those on cars with cone clutch and geared transmission. There are no gears in this friction transmission, and no beveled driving pinion or gears, which are expensive to replace, and require a great deal of attention.

Richmond, Ky.

CLIFTON WEAVER.

The Brush as a Hill-climber

When looking for a serviceable auto for apary work, do not overlook the Brush. It is a powerful little 10 h. p. machine—a regular little burro for grade-climbing, and as reliable as any in the market.

Redlands, Cal.

P. C. CHADWICK.

Forty h. p. Overland Run 25,000 Miles Among Queen-rearing Yards

Two years ago I invested in the best touring car the Overland people put out—a 40 h. p. machine costing \$1725 delivered in Beeville. So constantly have I used this car in the management of my out-apiaries that it has become a positive necessity as well as a decided luxury; and to do without it would surely handicap me in my business, my 15 yards numbering about 1200 colonies, scattered in a circuit of 85 miles—the nearest being 5 miles and the furthest 25 miles from home. This made it imperative for me, if I wished to keep pace with the times and the bees, to adopt a faster method than the wagon and horse. By the old way it took one week to get around and see the bees; but now I can see them all in one day if I wish. The old way required two teams and a buggy and horse. Since getting the auto, one team can do all the hauling, and the horse and buggy are not needed.

As to how both time and money can be saved by the use of the auto I will cite one instance. In last season's work, when the first fall rains fell, there were six yards that I knew needed about two hours of work at each. To work them in the old way would have required three days with wagon and team—a day to go out, and the best part of another to return. With the auto we worked the six yards, wife and I leaving home at noon on Tuesday, returning by the queen yard, caging and mailing 42 queens, and were at home at 6 P.M. Wednesday.

We never abuse the auto by making a dray of it, although we sometimes load a thousand pounds of honey in bare cans in the rear, carefully placing and packing to avoid chafing the inside finish of the car.

Unlike a wagon and team, we can run right into the yard, among the bees, with no fear of runaways or smashups. We have found the auto a great convenience in moving heavy loads of honey right out of the beeyard to a safe distance so the team could be attached. I believe I could pull a 2000-pound load on a trailer all over this country; but, unlike our friend Cavanaugh, whose pictured trailer he gave us last season, I have been too much afraid injury would result to my car by pulling a trailer, as it did to his.

Now as to the expense, which should be discussed and thoroughly understood before investing in an auto; for we can not operate a car without expense, any more than we can operate a team and wagon without cost. The first cost of a car is the first to be considered; next, its upkeep. If my car did no more mileage than my team, the cost of upkeep would be less than that of a wagon and team.

I have had a few minor breaks. Three transmission cases were broken in the first 3000 miles. These were replaced by the company free of charge. Later, after 18 months' use, an axle was broken. There have been also a few smaller troubles, all of which were easily adjusted. Gasoline and lubrication have been the greatest expense, as with heavy cars they average about a cent per mile. I have run some 25,000 miles, and to all appearances my car is as good as new, and I can not see why it should not run a hundred thousand miles. A new set of inner and outer tubes have been purchased only once, at a cost of \$174.

Beeville, Texas.

W. H. LAWS.

Pyrox fills the barrel with the apples that used to be on top. Write BOWKER INSECTICIDE CO., Boston, for book.

Our Homes

A. I. Root.

Jesus answered and said unto her, If thou knewest the gift of God, and who it is that saith to thee, Give me to drink, thou wouldest have asked of him, and he would have given thee living water. The woman saith unto him, Sir, thou hast nothing to draw with, and the well is deep: from whence then hast thou that living water? Art thou greater than our father Jacob, which gave us the well, and drank thereof himself, and his sons, and his cattle? Jesus answered and said unto her, Every one that drinketh of this water shall thirst again: but whosoever drinketh of the water that I shall give him shall never thirst; but the water that I shall give him shall become in him a well of water springing up unto eternal life.—JOHN 4: 10-14.

Ever since childhood I have been more or less interested in springs, and springs of "living water." Near my childhood home there were many springs, and in my play I had more or less to do with them. I built dams, had little sawmills, and made tubes of hollow reeds for hydraulic experiments. Since then our readers will remember I have written up springs more or less; in fact, I have visited some of the finest and largest springs in the world. Just of late I have been interested in making artificial springs, and this is what I want to tell you about to-day. We have artesian wells in our vicinity, it is true; but the artesian water is not as good as water from a spring. We also had quite a little expense, as we recently put up a windmill with a ten-barrel tank elevated twenty feet. This windmill, of course, gives us running water until the tank is empty; but where we open a half-inch pipe, a ten-barrel tank full lasts only a few hours. In making our garden, I very soon discovered that, when we have excessive rains, such as we have had this past winter, it is extremely important that our ground be underdrained, and I finally purchased a thousand tiles, shipped from Georgia, for this purpose. Right at the head of our garden, at the highest ground, we commenced our line of tiles and went down (to get good underdrainage) between four and five feet. Then the tiles were carried along with just as little fall as possible and have a running stream. After carrying them down three or four hundred feet we found the ground so porous that the water we had secured at the head was lost in the porous soil. In order to obviate this we ran the tile back to where there was a pretty good stream running into a half-barrel or keg. This half-barrel had a wire-cloth partition across the middle in order to prevent sediment from going into the iron pipes that are attached to the barrel. We used old iron pipe, second-hand, that cost but little, in place of the tiles; because when the water once gets into the iron pipe it is secure and can not soak into the loose ground nor evaporate. Well, in the fall we were greatly pleased to find that this half-inch iron pipe gave a full half-inch stream. This stream was allowed to run into a tank of water in the duck yard in the lower part of the garden.

I now want to digress a little to tell you that down here in Florida we have an abundance of rats. They are not the same kind of rats that we have in the North, but they are bad enough. Where we feed chickens by scattering the grain on the ground, the rats will come in and do a thriving business. Well, I have explained to you already that we head off the rats in our poultry-houses by keeping all of our grain and feed in galvanized iron tubs, and these tubs are suspended from the ceiling by three wires. Now, we can not do this very well in case of the ducks, because they can not climb up and get the feed out of the tubs; but I have got on to a plan which seems to answer about as well. Our corn and wheat, or what else is fed to the ducks, is put into the bottom of these pans where the running water flows in. The ducks, of course, like it all the better for being under water, and so far the rats have not discovered any plan whereby they can get the grain at the bottom of the pan. Now, with ducks we want running water; because if the water is not changed constantly, as any one who has had experience with ducks will recognize, it soon gets very muddy and foul; in fact, a water-pond for ducks that has not a running stream to keep it supplied and to keep the water moving will soon become any thing but a pleasant sight or smell.

Well, this stream of running water has given me a great deal of pleasure every time I have passed it. There it runs, day and night, week days and Sundays. There is no letup nor stoppage—at least there has been none so far, and we are now in the middle of quite a severe drouth, yet my artificial spring continues to work just as it did at first. The point I am getting at is this: Almost any of you can have a spring of running water on your premises if you have an acre of ground, or, better still, a few acres. Rising ground, of course, is an advantage, because then you can get the necessary fall without any great expense.

Just a word in regard to a suitable place for locating these artificial springs. Some of our older readers may remember that some years ago I made a visit to Father Cole, as he was called—the man who put out the book entitled "Making the Water Captive." Well, Father Cole told me that he had discovered that most springs are at the bottom of a ravine with a surface-water drainage at the upper part. If you go out in the woods or in the fields, and find a place where the water has been running when there are abundant rains you will find, by digging down, that there is surface-water running at almost any season of the year. The best place in the world to do tilting for an artificial spring is in one of these surface-drainage spots. You may object at the expense of the tile; but if you are doing any thing in the way of making garden or

raising crops you will find that the tile will be an exceedingly good investment without considering the worth of this running spring. What is prettier or more exhilarating than to see a stream of water that continues to give pure, clean, health-giving water? The water in our spring which I have described is so soft that it washes with soap just as well as rain water. When visitors are around our premises they always utter an exclamation of surprise and delight when they see the corn for the ducks down at the bottom of that pan of clean sparkling water.

I have had great pleasure in raising ducks, as I have told you before. I have had excellent success; have scarcely lost one unless by some accident, and I think one great reason is that they have running water all the while—all they can consume. When they get to a sufficient age I give them this same running water to bathe, splash, and play in. Now, there may be something in animated nature more pleasing and more thrilling than young ducks playing in beautiful clean running water; but if so I have not found it. Whenever I feel dull, or when inclined to feel overburdened with care, nothing rests me like going out and looking at these young ducklings in their play. By the way, are there any of God's creatures as joyous and full of fun, and as happy, as a lot of ducklings? Just now I have a Leghorn hen leading about a flock of twenty-nine taken out of an incubator. They are just three days old to-day, and I wish the readers of GLEANINGS could get a glimpse of those twenty-nine ducklings as they rejoice and give thanks to God for the little lives he has given them—at least so I understand it when they flop their wings and start off full of exhilaration and thanksgiving for life. Just after dinner to-day, when I had first put them out on the grassy plot where they stay, and where they had been playing in the dropping water, the sun came out, and all at once they started on a sort of jubilee. I called it their Indian waltz, and called Mrs. Root in a hurry to come out and see them perform.

If you have ground on your premises that you find higher than your dwellings, of course you can have this water piped into the house. In this case you would, of course, be careful to have your tile laid in ground that is not near to the barn or stables or other outbuildings. None but those who have tried it can realize what a blessing it is to have a stream of water running right into the kitchen. Even if it does cost some money, how can the money be better invested? If you have a sufficient stream or vein of water, even if it should be lower than your dwelling, by use of a hydraulic ram you can even then have a

stream of water running into your dwelling and to your barn and stable. Even a small stream, where it runs continuously day and night, week in and week out, will afford quite a quantity of water, as you can readily determine by figuring it up. The diagram will give a pretty clear idea of our spring.

Our older readers may remember that the fourth chapter of John is the one that I learned to read in Spanish when I was on the island of Cuba. Ever since that time this chapter has had a special attraction to me; and when I saw that beautiful stream of pure water running into that tank, and overflowing, giving life and enjoyment to my ducks, I kept thinking of this passage, especially of the living water. Just now in our nation there are a great number of people who are interested in the matter of drink. There are those who drink that which destroys both body and soul; and, worse still, who are engaged in manufacturing and recommending it, and demanding laws so that they can furnish it to their fellow-men. Do you think those who are interested in this sort of drink are the ones who are going to inherit eternal life, as mentioned in our text? What is to be the outcome of the great inventions and discoveries that are now coming so thick and fast? We have wireless telegraphy, the dictaphone (that I am using now while I am talking to you), the flying-machine that the Wright brothers are still pushing further and further, that is to be the great excitement of the whole wide world in just a few weeks more, and other discoveries that are coming thick and fast. The question naturally arises, "What about the future, and what is coming next?" Those of you who are getting old, like myself—say those who have passed the period of threescore years and ten, I wonder how many of you are thinking of what will be going on in this world of ours after we are dead and gone. Shall we know of earthly things after we have passed this brief stage of life? Our text tells us that we shall. But does it seem likely that those who are spending their lives for self and selfish purposes, with no thought of the future, with no thought about humanity, nor care nor regard for God or his creatures, shall inherit eternal life, and know what is going on, and what the outcome shall be of this world of ours? What did the dear Savior mean when he said, "The water that I shall give shall be a well of water springing up into eternal life," or into everlasting life? What shall we do, as the woman said, to have this water that we thirst not?

"Living water," as I understand it, is accepting Christ Jesus as our Lord and Savior, obeying his commands, and following in his footsteps so far as we can. If we commence to study his life here on earth, and the words that he spoke, we shall very soon have it plain before us what it is to be a follower of the Lord Jesus Christ. Thus there is the promise that they shall have eternal life, and this spring of water that is to be given by this one who has decided to be a

follower of Christ is like the little spring I have been telling you about—the little stream of pure clear water that runs on day and night, week in and week out, for ever and for ever. This stream given by any Christian or follower of Christ is to be a life devoted to the benefit of its fellow-men in lending a helping hand, even as Christ Jesus himself lends a helping hand to bless and help and alleviate the ills of humanity.

Pure water is life and health, not only to humanity but to every living thing. I have spoken before of the duck. Perhaps no other animal cares for water, or wants it so constantly, as the little ducks. Water seems almost to them like air. They must have it always before them. They want it pure and fresh and sweet. They can not take their food without having constant access to water. Just to-day we have been moving the pen of little ducks so that they can go into the canal I have already spoken of, and enjoy themselves in the running water. They are separated by a fence from the matured ducks, because it would not do to let them get together. The feedpan is arranged close to the water so that, when they come to drink, they can take a bite at their feed. In order to do their best, I manage to have their feed close to them so they can help themselves whenever they feel prompted by hunger.

Now, this spring of living water that is promised to Christians is always constantly by you. It is not only an unceasing stream, but the amount is without limit. There is no limit to the work one may do to help his fellow-man if he is prompted by the love of Christ Jesus in his heart. And to such, and such only, is promised everlasting life. This spring of living water is to humanity what the running water is to the little ducks. It is, in fact, life itself.

Let me illustrate what I have been telling you by a little sketch of the last few days. I have mentioned the wicked boys who have been taking my ducks one after another on God's holy sabbath day, until I almost felt compelled to give up my plan of growing ducks in the water. However, after the boys were arrested, and one of them put in jail, I thought my troubles were over; but one morning, after a beautiful moonlight night, one of the older ones, fully half grown, was missing. Besides that, three more were gone out of the next size that came out of the incubator. Perhaps no one but those who have lost poultry in this way can understand the feeling of sadness that comes when, day after day, more poultry is missing. Of course, it is not the loss of the fowls altogether, but the knowledge that vicious and wicked people are becoming encouraged. It is probably boys or young men who are engaged in this kind of pilfering; and if the matter is allowed to go on unrebuked or unpunished it is encouraging a school of crime. Well, each time I lost any ducks I had a feeling of sadness or discouragement that took several days to wear off. This last time, when four were taken in one

single night, I felt not only that I must give it up, but that I was losing faith in the character of the good people in our neighborhood, and (I fear) to some extent losing faith in humanity. Of course, I prayed over the matter; in fact, I prayed more earnestly than I had for some time in regard to it. Finally I went off by myself and asked the dear Savior to give me peace of mind, and happiness and enjoyment, notwithstanding these discouragements, and begged for wisdom and understanding in taking care of the matter. Then I went on about my work, and finally succeeded in forgetting for the time being all about my troubles. All at once, when I was not thinking about it at all, and the matter had passed from my mind, a still small voice seemed to speak to me, almost as plain as words, "Lay not up for yourselves treasures on earth, where moth and rust doth corrupt, and where thieves break through and steal." Then it dawned on me that I had been giving too much thought, and making my happiness too much dependent upon the things of this world. I thank the Lord for this recent answer to my prayer; and, a little after, in talking with my neighbor, our good friend Mr. Rood, about it, he said he felt certain that no boys nor anybody else disturbed my ducks. After asking several questions about it he decided that some of the Florida owls that are out, especially during bright moonlight nights, were to blame. He was all the more sure of this when I told him that it was the first time I had let the smaller flock of ducks stay outdoors over night during the very warm weather we had. The older ones, that are fully half grown, had been outside some time. I asked him if it was possible an owl could take a duck as large as a good-sized chicken. He said there was no question about it. After shutting up all the young ducks we have had no more losses of this kind. My good friend Mr. Abbott also told me that whenever they had very bright moonlight nights (and I believe that here in Florida we have a brighter moonlight than anywhere else I have ever been) they were almost sure to hear a commotion among his poultry. Mrs. Root reminds me that there was a loud cackling among our chickens that same night. I didn't hear them as she did, on account of my deafness. Of course, the answer to my prayer did not bring back my ducks nor the pay for them, but it brought a feeling of relief to find it was pretty certain that it was owls and not the dear boys who "are of more value than many sparrows."

The *Sunday School Times*, in a recent editorial, said that we as Christians may thank God for difficulties, especially the difficulties that send us to the Lord in prayer. I must confess that much of my praying and most of my most earnest prayers are generally at the time when I get into trouble.

Now, this living water that Jesus furnishes to his followers is always on hand. It is always running, and it is always ready for our wants. He is always ready to hear our

prayers, and listens to our troubles and gives us relief, and relief in a way that will benefit and bless our fellow-men and not do them harm.

I have recently been reading in the papers the contest we are having in Ohio in regard to the liquor business. I have been amazed to see the way in which the daily papers treat the matter. I have such papers from different parts of our nation in our Southern home, and I am interested in noting the way in which they make reports. A great part of them seem to report the progress of temperance and intemperance as they would report the progress of the different political parties. Let us look at it a minute. The Anti-saloon League, in which I am and always will be interested, works for the good of humanity in spending its money and its means in benefiting and lending a helping hand to children and mothers, and all who need that kind of help. The competing parties in the contest are the liquor men, who have no interest at stake except the interest of making money—nothing to urge in the way of an uplift to humanity. The strongest argument they can bring to bear is that, if the liquor traffic is outlawed, hundreds and perhaps thousands will be thrown out of employment—that is, employment in the breweries and the distilleries. In view of all this I am positively amazed to think that so many counties in Ohio have, after having tried prohibition for a term of two or three years, gone back and voted the county "wet." It seems incredible that it can be a fair and honest vote. It could not be if the wives and mothers had a hand in deciding the matter. May God grant that they will soon have a hand. What for? That "whosoever drinketh of the water that I shall give him shall never thirst."

The *Chicago Advance* recently had an editorial in regard to melancholia*, and they seemed to treat it as one of the unpreventable and incurable diseases. I was surprised that they did not suggest that the one afflicted with melancholia should get busy (to use the slang expression) in working for humanity and spreading the Gospel of Jesus Christ in furnishing to humanity its living water that always refreshes and benefits and that does no harm. They ended their editorial by recommending that the best relief for melancholia is to get busy and keep busy, and this I can most heartily endorse. The past winter has been one of the busiest I ever passed in my life. During the past few days it seemed as though I had not a single minute, and sometimes hardly a second, to spare or to waste.

* My good friend, it is *sin* to indulge in melancholia—a grievous sin. It is an insult to the great loving Father who gave you a human life to live. He who drinks of that "life-giving fountain" mentioned in our text will find himself too busy in passing it on to a famishing and thirsting world to have time for such thoughts. It is the outcome of selfish indolence. I know, for I have *been there*. Say, "Get thee behind me, Satan," and then "get busy." Melancholia is the "stepping-stone" to the terrible "suicide mania."

SWEET CLOVER, AN UP-TO-DATE REPORT.

A field of forty acres on our Kentucky farm has been sown to sweet clover, the past season being the second after sowing. During the blossoming period, which lasted from the middle of June until the middle of August, the field was covered with honeybees.

Sweet clover is a legume. Practically the same bacteria live on its roots that live on the plant-roots of alfalfa. Some people will say alfalfa is so much better than sweet clover, why not plant it? How do they know if they have never planted sweet clover? We first used sweet clover as an inoculator for alfalfa. The bacteria developed much faster in the soil sown to sweet clover than that sown to alfalfa. I have noticed that the plants of sweet clover do not depend on artificial inoculation or fertilization as does the alfalfa-plant. Another advantage is that seeding may be later. The seeding of sweet clover may occur with us any time after the first of October up until the first of December. We have the entire season for the maturing of other crops before having to remove them for preparing the land for seeding.

MAKING SWEET CLOVER GROW.

On land where the following crops are grown—corn, tobacco, potatoes, or tomatoes—all that is required in preparing the soil for seeding is a deep disking with a sharp disk harrow, and a complete working with the float or plank drag. This levels and firms the soil without making it too compact; and when the seed is sown and lightly harrowed in with a sharp-toothed drag harrow that leaves small ridges and furrows, the soil crumbles around the small plants during the winter and early spring, which starts them off before other vegetation has made its appearance.

To sow as a soil-restorer, on old fields that are badly gullied, there is no preparation required. The seed is sown broadcast, about 25 pounds per acre, any time during the fall, winter, or spring.

The seed of sweet clover should be sown thinly on old and tired fields, then the stalks will be large and branching, bearing much seed and quickly re-seeding the field. The brushy stalks may be cut and placed in the small washes, which they stop by catching the silt and small trash that would otherwise be washed away and lost.

A description of the sweet-clover roots will show that they are a high-class fertilizer. Unlike the roots of other leguminous plants, those of sweet clover are somewhat fleshy and not fibrous. During the first year the roots reach far into the ground and draw up from considerable depth an abundance of plant-food, which they store up for the second year's growth. On the death of the plant, at the close of the second year, the fleshy roots decay more rapidly than the fibrous roots, and their nitrogen becomes more readily available for other crops.

PREPARES THE LAND FOR ALFALFA.

We think sweet clover is one of the finest things in use to prepare the land for alfalfa. Sow to sweet clover for one year; break the land, turning under the young growth the second spring about the first of May, and cultivate until ready to seed to alfalfa. The germs of bacteria will increase rapidly, and the soil will be filled so full that the alfalfa-plants will grow right off and make two or more cuttings the first year after sowing in the early fall. As a soiling crop, it is right up to the front. Combined with bluegrass, it makes one of the finest pastures known to stockmen. Unlike alfalfa, it improves by being pastured; yet again, like alfalfa, the stock have to become accustomed to it before they will eat it with a relish. But when once they have learned to eat it they prefer it to all other grasses.

As a pasture for hogs, the chief difficulty lies in the fact that the hogs want the roots as well as the tops. They eat the grass readily from the first, seeming to like its peculiar flavor, and are also fond of the hay, eating it more readily than that of red clover. One of its many good qualities is that cattle may be fed exclusively on sweet clover, and under the conditions most favorable to bloating without any danger from this trouble. The principle which gives it its bitter taste effectively prevents the fermentation that results in bloating.

I believe that every farmer who owns hill land not suitable for alfalfa should give sweet clover a trial. Then, after a few years, when sweet clover has made good, alfalfa will be the next in order.—*Farm and Fireside.* J. W. GRIFFIN.

NO. 8

Editorial

NEXT issue will be largely devoted to the subject of making increase and strengthening weak nuclei. This discussion will be especially seasonable this spring.

A CORRECTION.

IN our editorial notice of the new bee journal, the South African *Bee-keepers' Journal*, in our December 15th issue, we gave the address as Johannesburg, Natal, S. Africa, whereas Johannesburg is in the Transvaal. The initials of the editor are also "G. S." instead of "G. F." Oettle as given.

NEW SUBSCRIPTIONS ROLLING IN.

IN spite of the severe winter losses, new subscriptions are rolling in at a faster rate at this time of the year than we have ever known before except once. The last month shows a gain of nearly 600 new subscribers. It looks as if the winter just passed had not chilled the ardor of a large number of our beekeeping friends, for renewals are coming in at the same steady healthy rate.

THE DEATH OF NEW JERSEY'S FOUL-BROOD INSPECTOR

WE are sorry to announce the death of Prof. John B. Smith, State Entomologist and Foul-brood Inspector of New Jersey. Prof. Smith worked hard for foul-brood legislation in his State, and, with the help of others, finally succeeded in the enactment of an excellent foul-brood law. There was great need of it. He was a good entomologist, and did splendid work in eradicating bee diseases. New Jersey can ill afford its loss. His successor possibly may not be appointed for some time.

HONEY PROSPECTS FOR THE COMING YEAR.

REPORTS thus far received, in spite of the severe winter losses in some localities, are optimistic, forecasting an old-fashioned honey-year. While it is true there will be a light force of bees in some localities to gather the honey, it seems to be generally felt that this is going to be a clover year in the East. A large amount of snow has cov-

ered almost the entire clover belt for the entire winter. Such a condition, it is felt, means clover and honey. There are a few localities that report that last fall's drouth killed clover out entirely; but these are few and scattering.

In the irrigated regions of the West there will be the usual run of alfalfa honey. Conditions in California, so far as the sage crop is concerned, look much better than they did a month ago; but it is feared that the rains came too late to do any thing better than to make a light yield.

EXTRAVAGANT ADVERTISING OF FIVE-BANDED BEES.

IN our last issue, page 189, in Straws, Geo. M. Steele, of Philadelphia, desired to have Dr. Miller retract his statement to the effect that there were not a dozen colonies in the United States showing *all* five-banded, for he said he could disprove the statement with the bees. Dr. Miller very properly replied by saying that he did not make the statement attributed to him and referred him to the editor. As we were in Florida when the Straw appeared, it is proper for us to reply:

Mr. Steele, in a letter which he submitted to Dr. Miller, says, "I have sixty colonies that will go one better in our 95 per cent of the workers, and some five that will run golden to the tip in 100 per cent of the workers." We cheerfully retract, and offer our congratulations. But we still venture the opinion that Mr. Steele is the only breeder of goldens that can show this high percentage of yellow. If there is another, let him hold up his hand *and furnish the proof*. Mr. Steele has already done this to our satisfaction, and it is but fair that the others should do the same.

What we have particularly protested against is advertising "five-banded bees," and furnishing, after the money is paid, three and four banded bees. That is what makes trouble; for if the "ad" appeared in these columns we are asked to "arbitrate" or make the other fellow quit advertising what he has not for sale and can not furnish.

WINTER LOSSES OVER THE COUNTRY.

REPORTS are few and scattering, although it is safe to guess that the total loss will be much more severe than for many years past. In most localities where cellar or out-door wintering prevails, and the bees had sugar syrup or equally good table honey, there were practically no losses. Cellar wintering during the past winter, where the conditions so far as ventilation and humidity were right, has again demonstrated its superiority in extremely cold localities or cold weather. Bees well housed in double-walled hives on good stores have, as a general thing, wintered well. The following is a fair sample showing the value of protection:

I can inform you how my bees wintered. Home yard, chaff hives, in open, wintered perfectly; sealed, protected by building, loss 20 per cent; wintered, no loss.

Out-apiaries, yard A, single-walled, in open, loss little over 80 per cent; yard B, as above, 75 per cent. yard C, as above, 70 per cent. This is the greatest loss ever experienced. Had the bees been all packed, the results would have been better.

DECATUR, ILL., March 17.

W. S. ZERRING.

In many localities last fall the bees gathered considerable fall honey. Where this was the case some heavy losses have been reported. A queer thing about it is that bees south of the Ohio River have died as well as those north of it. The unusual cold caused them to consume more stores than usual, causing starvation and sometimes dysentery.

The greatest losses seemed to have occurred on or near a line running through the center of the following States: Iowa, Wisconsin, Illinois, Indiana, and Pennsylvania. Losses are reported in Oklahoma, Kansas, and Missouri. Fair to good wintering is being reported in Minnesota, Michigan, Canada, New York, and the New England States. In Minnesota, Michigan, Canada, and New York, where the bees have been housed in cellars or in good double-walled hives outdoors, the losses have been light.

As we said about a month ago, losses will be heaviest on the dividing line where protection of the hives is usually practiced, and where protection such as outside winter cases or double walls is seldom used. Strangely enough, losses are the lightest where it is the coldest.

WHAT TO DO WITH WEAK DWINDLING COLONIES, AND HOW TO BUILD THEM UP.

Fortunately, spring has opened up very auspiciously. Brood-rearing is starting up well, and bees everywhere will hold their own, providing a severe cold spell does not follow. No one can tell. As a general thing it does not pay to unite little weak nuclei. If the weather is unfavorable they will die whether united or left on their original stands. When united the old bees go back to the old stand. Our Mr. Mell Pritchard makes the suggestion that it would not be a bad idea to unite a lot of weak ones into one hive and put them in a dark cellar and keep them there for a week or ten days, and then set them out. This will give them

an opportunity to form into one colony, and at the same time lose their sense of location, and start over again.

In this issue Mr. Doolittle has an excellent article on making increase. Many of our friends who have lost heavily, and wish to make the survivors go as far as possible, can read it with profit. See page 227.

The Alexander plan of building up nuclei into strong colonies has given splendid results. As many do not have his book, or have forgotten when it was published in these columns, we give it here:

As soon as they have some uncapped brood in their hives, take them to a good strong colony; remove its cover and put a queen-excluder in its place, then set the weak one on top of the excluder and close up all entrances to the weak colony, except what they have through the excluder, down into the strong colony below. Leave them in this way together four or five weeks; then separate them and you will have two good colonies and will have saved yourself all worry about these weak colonies being robbed, chilled, or starved. When we are feeding the other colonies we usually give these a few spoonfuls of the warm syrup in a comb next their brood. This encourages them; and if there is not more than a cupful of bees they don't get much from the feeder under the strong colony. I have explained at bee conventions this way of saving these little colonies, and have received very complimentary letters afterward from prominent beekeepers, saying that this idea was worth more than \$100 to them.

WHAT TO DO WITH EXTRA QUEENS.

If any of the stronger colonies have impurely mated or undesirable queens, it will be a good time to requeen with pure blood from the united nuclei. Of course, the objection might be raised that a queen that will not raise bees that will pull through a winter like this should not take the place of a queen whose bees did stand the rigors. But it may be that the pure queen did not have the same chance that the poorly marked queen had. For example, we find that our colonies that supplied nuclei or pound packages of bees in September and October, in most cases died because they had been robbed of a very important part of their bee family. If, for example, it is necessary to go into winter quarters with three pounds of bees, and we take away one pound, we run the chances of losing the whole colony.

DEATH OF S. T. PETTIT.

MR. S. T. PETTIT, of Aylmer West, Ont., Canada, died on the 25th day of last month in his 83d year. He was the father of Morley Pettit, Provincial Apiculturist of the Apicultural Department of the Ontario Agricultural College of Canada, and also father-in-law of Mr. R. F. Holtermann, formerly editor of our Canadian Department, and now an occasional contributor to these columns.

For many years Mr. Pettit was one of the most prominent bee-keepers of Ontario. He was a man of pronounced opinions and of sterling qualities. Among other things he was the discoverer of the plan for making bees fill the outside rows of sections as well as the inside. This was done by putting perforated dividers or separators out-

side of the outside rows of sections. This made a clustering-space for the bees, approximately one inch thick between the outside of the hive and the combs themselves. The general effect of this thick wall of bees was to make the comb-building temperature the same as the interior of the super. In connection with this, Mr. Pettit used long narrow wedges between the bottom of the sides of the hive and the bottom board, so placed that the entrance would be enlarged. This would make the front end of the bottoms of the brood frames out of reach of the bees. The purpose of this was to cause the incoming fielders, laden with honey, to go to the *sides* and back end of the hive and up to the outside rows of sections, and there deposit their nectar.

Mr. Pettit was also the inventor of a special honey-strainer used during extracting. A description of this will be found in the latest edition of the A B C and X Y Z of Bee Culture.

During the time when there was some talk of feeding bees sugar syrup to produce comb honey, Mr. Pettit came out in all the bee journals, most strenuously opposing the proposition. He felt that it would be nothing more nor less than a fraud on the public; and while he admitted that conscientious beekeepers would sell such a product for only sugar honey, he felt that many others, not stating its source, would attempt to sell it for natural floral honey. Others joined with Mr. P., and the matter was soon dropped.

During the five months preceding his death Mr. Pettit was a great sufferer; but in those days, we are told, he loved to speak of his Lord and Savior.

WHY BEEKEEPERS SHOULD PRODUCE MORE COMB HONEY THIS YEAR.

We have already alluded to the fact that the markets are practically bare of fancy and No. 1 comb honey. There are some few lots of uncandied comb honey left, but that is about all. There is no lack of extracted, even though last year was the poorest on record for the production of honey. This goes to emphasize the importance of producing more comb and less extracted. But right here a caution should be entered. Nothing but the very finest of table honey should be put into sections. There are several grades of Southern honey of very fine flavor; but because they are unknown to the Northern markets that take comb honey they can not be put out in that form. About all the kinds of honey it is safe to put into sections for a Northern market can be counted on the fingers of one hand. Let us name them over. First and foremost we may put clover. This may have a little mixture of sweet clover or basswood without hurting it in the least. While the pure basswood comb honey will pass muster, it is such a scarce article now that we find it only now and then mixed in varying quantities with clover.

Next in order we put mountain sage. It is of fine flavor and does not granulate readily. We place it ahead of alfalfa because it does not candy. Alfalfa makes a fine honey for sections, excellent in flavor and body; but it has just one bad defect—its tendency to candy too rapidly. Some go so far as to say that *all* alfalfa should be extracted. We do not share this opinion, because alfalfa comb honey, if sold before the holidays, will bring enough better price than alfalfa extracted to warrant its production.

These three sources—alfalfa, clover, and sage—cover the main dependence for section honey. We may now add to this list, for certain localities, buckwheat; but buckwheat comb honey should be sold only in eastern markets, particularly round Albany, where it seems to have a good demand. Thistle honey and willowherb comb honey make a fine section honey; but the localities where they can be produced are so limited that they are scarcely known in the market.

There is some excellent Texas honey, such as huajilla (pronounced wah-heel-ya), and catelaw. These make excellent comb or chunk honey. But these honeys rarely find their way into Northern markets. Local consumption seems to take care of them; and therefore it follows that those who are located in the clover, alfalfa, and sage districts should produce as much comb honey as possible this summer. If there should be any thing like a good flow of honey this season the market is liable to be flooded with extracted.

In this connection too much importance can not be placed on the necessity of having all the sections well filled with either No. 1 or fancy. No. 2's are slow sellers, and very often it pays better to cut them out of sections entirely, pour good extracted honey over them, and sell the product in pails in the local markets.

It is equally important to use strong well-made shipping cases. They must be neither too large nor too small; should be provided with corrugated paper at the top and bottom, and it will pay in the end to use cartons. The main reason why comb honey has caused so much trouble between buyer and producer is on account of imperfect packing. It would not cost half a cent a pound to put up comb honey *right*, and the half-cent investment will bring back five cents or more per pound, and sometimes even ten cents more; because the buyer does not want broken-down comb honey at any price.

Careless and ignorant beekeepers have only themselves to blame for the state of the comb-honey business; and it is surprising how even our up-to-date producers—some of them who write for the papers—still put up their comb honey. They remind us of the economical husband in the current-date cartoons. There is a false economy and a real economy. If we put the comb-honey business back where it originally was, we must, first of all, pack it properly, not only in the car itself, but in the shipping

cases. In less than car lots carriers should always be used with a liberal amount of straw under the cases.

LIST OF QUEEN-BREEDERS WHO AGREE TO BOIL THE HONEY THEY USE IN MAK- ING QUEEN-CAGE CANDY.

PRACTICALLY all the queen-breeders in the country, except four, have agreed to boil all the honey they use in making queen-cage candy. One writes that he is in a locality where there has never been any foul brood. He even goes so far as to say that there is none in his State. "Why go to the expense of boiling?" he asks. Another one says there is no foul brood within five miles of him. The last man, and he is one of our prominent breeders, ought certainly to boil his honey, because we know that foul brood is not far away, and it may ultimately work into his yard before he knows it. We do not feel like giving the names of these breeders, as the trade might refuse to buy queens of them. We feel sure they will be glad to fall into line after we put the argument up to them a little stronger.

The fact is that two or three of the leading foul-brood inspectors of the country have had pretty good proof put before them, showing that the disease had been carried into localities through queen-cage candy; and when it is so little trouble to boil the honey, every queen-breeder should comply with this simple precaution.

The following is a list of the queen-breeders who have agreed to boil the honey used in making queen-cage candy:

Herman Ahlers, Necanicum, Oregon.
F. M. Babcock, Fredonia, N. Y.
Mrs. J. W. Bacon, Waterloo, N. Y.
H. L. Beaty, Heyburn, Idaho.
E. W. Brown, Willow Springs, Ia.
Geo. J. Brown, Tustin, Cal.
H. C. Clemons, Boyd, Ky.
Benj. B. Davis, Springhill, Tenn.
John M. Davis, Springhill, Tenn.
W. J. Forehand, Fort Deposit, Ala.
N. E. France & Son, Platteville, Wis.
D. T. Gaster, Randleman, N. C.
John H. Gibbs, Berlin, Md.
Jos. Gray, Wasco, Cal.
J. E. Hand, Birmingham, Ohio.
Geo. B. Howe, Rock River, N. Y.
S. J. Maltby, College Point, N. Y.
J. P. Moore, Morgan, Ky.
H. G. Quirin, Bellevue, O.
G. H. Rea, Reynoldsville, Pa.
L. H. Robey, Worthington, W. Va.
The A. I. Root Co., Medina, O.
E. A. Simmons, Greenville, Ala.
P. G. Snyder, Swarthmore, Pa.

We have heard from two or three other queen-breeders who say they have never had any foul brood in their locality. One said that there had never been any in his State; but the fact is, these men can never determine absolutely whether their honey is free of infection or not. We have known of cases where European foul brood got a pretty good headway in a queen-breeder's yard before he knew it. Now, this man had been sending out presumably healthy queens in cages having candy made with honey from that same yard. European foul brood does not manifest itself quite so strongly as the American type. Then, again, American foul brood may exist in a hive of

strong vigorous Italians a couple of years before the owner knows it. There will be only here and there an occasional cell. We remember in particular one case of looking over a man's bees. He very confidently asserted that there had never been any foul brood in his locality. When we opened one hive we thought we detected the familiar odor of foul brood. On applying the nose a little closer, we found, sure enough, a faint odor of what we felt sure was the disease. We went through that colony three different times before we actually found a cell containing diseased matter. There were no perforations; but there were just two cells that showed that the disease was present beyond a question. If we had not detected the odor we would have passed that colony as O. K.

At other times there may be perforated cells not manifesting much odor. A good deal depends on the condition of the weather. A slight breeze will carry off any odors so that they will not reach the nostrils of the inspector. We wish to say in all seriousness to our friends the queen-breeders who do not think it necessary to boil their honey, they are taking a position that is dangerous to the industry. We like the position taken by Mr. J. P. Moore, who says:

Kindly add my name to your list of queen-breeders who boil all honey used in making queen-cage candy. I fully intended to write you in reply to your editorial, but in the rush of business I forgot to do so.

I have honey that I *know* is all right; but, as you say, unless *all* queen-breeders boil the honey used in queen candy, disease is likely to be scattered in some parts of the country.

Morgan, Ky., Oct. 12.

J. P. MOORE.

There are, perhaps, some queen-breeders who scout the idea of foul brood being carried through queen-cage candy. We have talked with a number of the foul-brood inspectors during the past year, and practically every one of them agrees that the disease may be carried in that manner. The very fact that foul brood is breaking out in new localities into which no bees have been shipped, and neither combs nor brood, is somewhat significant. If any one has any doubt on this point, let him write to Mr. Geo. F. Demuth, formerly foul-brood inspector of Indiana, now of the Bureau of Entomology, Washington, or N. E. France, Platteville, Wis., who is the oldest foul-brood inspector, in respect to his years of service, in the United States.

DIRECTIONS FOR BOILING.

Some have asked for directions for boiling the honey. It depends somewhat upon the consistency of the honey, but ordinarily we add about a pint of water to the gallon and boil it for seven or eight minutes. When cool, if the honey is then thicker than it should be for making the candy, it shows that a little more water should have been added. If the honey is very thin in the first place, less is needed. At our first attempt, we did not thin the honey; and it was so waxy and scorched after the boiling that it was unfit for queen-cage candy.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

POULTRY in the United States, in 1910, according to Bureau of Census, was worth 14.79 times as much as bees. [Bees are not so far behind as one might suppose.—ED.]

"THE INCREASED honey-yield which is possible by even a reasonable amount of effort in selecting and breeding bees is little realized by the majority of us."—Arthur C. Miller, *American Bee Journal*, 50. Right you are, Arthur.

THE ORIGIN of the plan of starting queen-cells on a horizontal comb seems to be in doubt, p. 177. It may be labeled "Made in Germany." Haven't time to look it up now, but I first saw it in a German bee journal, and gave it in a *Straw* a few years ago.

F. P. CLARE, you won't mind if I revise your figures, p. 179, will you? You took the word of some one else for it that the Langstroth frame is some two square inches less than the 16×10-inch frame of Mr. Simmins. Figure it up for yourself, and you will find that the Langstroth ($17\frac{1}{2} \times 9\frac{1}{2}$) contains $160\frac{3}{4}$ square inches, a trifle more than the 160 square inches contained in the 16×10 frame!

J. L. BYER, *American Bee Journal*, p. 48, says that in Ontario the claim that Italians are more immune to foul brood than blacks refers only to European foul brood, not to American foul brood. Italians being worse at robbing than blacks, his experience is that they contract the disease oftener by robbing than the blacks. He thinks it's all "moonshine" about resisting the disease after it is once contracted. [Byer is right.—ED.]

"THE SPECIALISTS who are producing extracted honey, and are making the most money, do not average over 50 pounds to the colony."—Wesley Foster, *American Bee Journal*, 46. That's quite a bit below the general estimate; but so much the worse for the general estimate. [It depends upon what you mean by "general estimate." Our A B C and X Y Z of Bee Culture puts the average for comb honey at 35 lbs., and from 25 to 50 per cent more for extracted.—ED.]

MARCH came in like a lion and went out like a whole menagerie of lions. [It is like a lamb hereabout. This 5th day of April it is a good deal like the weather we left in Florida. The only thing we fear is that it will not last long. However, Dame Nature has been giving us a long steady cold, and we are hoping that she will now give us enough warm weather so that we can save the remnants of our colonies that did not die in winter.—ED.]

REPLYING to G. L. Tomson: H. A. King never published *The American Bee Journal*; but if I am correct he or his brother, A.

J. King, published another bee journal. I do not think the patent on the American hive was ever annulled. Rev. L. L. Langstroth claimed it was an infringement on his patent, and there was much bitterness about it. Shortly before the patent expired Mr. King came out in a statement that his conscience would not allow him to take money for it, but I never heard that he refunded money he had taken or made any reparation to Father Langstroth for infringement. [A. J. King published the *Beekeeper's Magazine* for a number of years; but H. A. King and A. J. King were associated together in the manufacture of bee supplies in the early 70's.—ED.]

WHEN I GOT through reading April 1st GLEANINGS I couldn't tell whether a two-cycle piston with an exhaust cylinder escapes the gas of the planetary system better than a $167\frac{1}{2}$ h. p. transmission or not. Any way, I sympathize with that fellow who grew twenty years older in ten years through worrying about hauling bees with horses, and I'd like to go back 20 or 30 years and begin over again with autos. [Say, doctor, you are badly mixed up in automobile nomenclature; at any rate, you do not have to know about the inside mechanism of an automobile, neither is it necessary to understand the function of the carburetor, transmission, and all such, to be able to drive the car. But it is mighty convenient to know all of these things when it takes a notion to stop ten miles from nowhere. You are not yet too old to learn. A. I. R. is driving a little auto, and it is not often when the machine "balks" that he can not make it go.—ED.]

STILL AIR at zero is less of a hardship for a colony than a gale with the temperature 30 degrees higher. Never mind about crediting that to Allen Latham, page 212. Allen won't mind if I steal his thunder. I can't fix it up in quite so good shape in my own words, and it's a truth too little recognized. That's why it may be harder to winter outdoors here than in some places a long way north of here. There are times here when hour after hour, if not day after day, we don't have air—just wind. And it's no 30 degrees above zero either. [It is true that still air, although the temperature be much colder, is not nearly as severe on bees as a warmer temperature when a gale is on. This shows the importance of suitable wind-breaks for bees wintered outdoors. There may be a gale of wind outside of the beeyard and yet the air be almost quiet inside. We have seen this time and time again at our home apiary here in Medina. The outside of the yard is surrounded by tall evergreens on the north and west, while the east and south sides are protected by factory buildings.—ED.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

That is a good point made by Louis H. Scholl, page 38, that the beekeeper who has every thing in readiness for a crop of honey can look the future bravely in the face and feel sure he will conquer.

Riding by rail recently from Washington to Detroit I saw but two yards of bees, and one of them consisted of a few old box hives. This looks as though the country were not overstocked as a rule.

Some persons hesitate to start an outyard because they have no horse; but Mr. Demuth, of the Department at Washington, told me not long ago that he had hired a horse for this purpose at an expense of not over fifteen dollars.

It is interesting and sometimes amusing, and almost always instructive, to notice how different persons look at a particular subject from different angles. For instance, Mr. Wesley Foster, page 71, Feb. 1, gives the statement of Mr. F. Rauchfuss that comb-honey markets have been developed which demand Western honey, and pay a good figure. Now, one would naturally infer that those Colorado beekeepers had worked up a special market for Western or alfalfa honey; but I was talking the other day with an extensive and very intelligent beekeeper from the middle West who claimed that this is not true, as the older States had worked up the comb-honey demand or market in the East, and the alfalfa beekeepers had just stepped in and were reaping the benefit of markets already developed. He stated further that in the past, in one or more instances, he had established a market or demand for comb honey at an expense of 25 cents a pound to begin with. If this were all, it would not be worth talking about; but he said further that those Western beekeepers were doing great injury to our Eastern markets, not because of the quantity of honey, for there is a demand for all, whether from the East or West, but by putting honey on our Eastern markets that will granulate before it is consumed, thus disgusting alike the consumer and retail dealer who had previously used only Eastern honey that granulates more slowly. To my mind there is no honey produced in quantity that compares with good alfalfa granulated honey, with all wax removed; and if a market could be developed for pure granulated alfalfa honey or for "honey butter," as some call it, I believe it would be for the mutual advantage of producer, dealer, and consumer.

Then, again, there is the wintering problem, and it is a problem of great importance.

How differently it is regarded by different beekeepers! There is my good friend, Arthur C. Miller, a very careful observer, who says, page 73, Feb. 1, that when the external temperature has been nearly level for a day or two there will be found to be a difference of only one or two degrees between the inside and outside of a hive, whether in single or double walls, and I believe he states the truth. Then there is my friend Byer, a rather small man who does some large thinking, who has found the temperature between the inside and outside of a hive to vary from twenty to nearly fifty degrees, and I believe his statements equally true. Whence comes this great difference? In wintering bees in the extreme North there is always one major problem to be solved: How shall we get rid of the moisture generated by the bees, and mingled with the air and heat of the hive, and retain the heat produced by the bees? If we wished to get rid of both heat and moisture, or retain both, it would be simple indeed; but the heat must be retained and the moisture thrown off. Friend Miller goes at it one way and Byer another. Miller would ventilate his hive freely, giving about nine square inches of opening to each cubic foot of space inside his hive, with the result, as he says, of but one or two degrees difference between inside and outside temperatures. And it seems reasonable that it should be so. If we were to ventilate our dwellinghouses in the same proportion, a room 15 feet square and 9 feet high would require an opening to the outside equivalent to six good-sized windows with the sash out. Presumably the temperature would be but one or two degrees warmer inside than outside, whether the walls were single or double. It might dispel the great white plague; but, oh my! wouldn't we shake and shiver with the temperature 20° below zero, and the wind blowing a gale? Mr. Miller would compensate for this loss of heat by the use of dark paper to absorb the heat of the sun; but the sun does not shine nights nor on cloudy days, and there are many such.

On the other hand, Mr. Byer has a smaller entrance open and well packed, and lets the moisture percolate slowly through the warm packing that retains a large portion of the heat. That the moisture goes through the packing is readily seen by placing a pane of glass on top of it, when it soon collects moisture on the under side. That the heat is retained is proved by such observations as Mr. Byer and others have made. With suitable packing and small entrances (a half-inch square is enough if so arranged as not to become clogged) I have found hives and combs as clean and dry in March as in November whether the sun shone on them or not. I have also found the constant change of temperature a decided disadvantage.

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas

A MOST USEFUL HAMMER.

Spilling a boxful of tacks or small nails in the soft dirt covered with trash is enough to make anybody lose his temper unless controlled. But the writer dropped nearly a quart of small tacks into just such a place, and did not lose his temper. Instead, the first thought was about that magnetic hammer mentioned several years ago in this department, and which kind has been in use in our work ever since. With this hammer every one of the tacks was quickly picked up clean from dirt and trash, and they were all in the box again, looking as though they had never been out of it. This is not the first time that one of these tools has done such service, either. The magnetic hammer has an important place in the beekeeper's outfit once its worth is known. It does not pay to purchase the cheap kind that are so often seen in use, and which do not give very good satisfaction. A good strong magnetic hammer that can be depended upon at all times can be used in many ways.

THAT HORTICULTURAL NUMBER.

GLEANINGS can pride itself with a piece of work that is of more value to the country at large than any other publication on the subject of "bees and horticulture." The pages of the March 15th number are so full of this information that it is a veritable bulletin on the subject. Ah! if the dissemination of such exceedingly valuable matter could be placed in the hands of every farmer and fruit-grower, and if it could reach the multitude of persons who are not acquainted with or do not understand the interdependent relations between the honey bee and plant life, what would be the result in better and larger crop productions affected by the proper pollination of the flowers and blossoms? But GLEANINGS, with its wide circulation, is doing a great work through this "horticultural number." Every reader should preserve this copy and make use of it whenever possible. [We have already sent out over a thousand copies of the March 15th issue to fruit-growers whose names were furnished us by our readers in various parts of the country. We sincerely hope these may be the means of bringing about a greater appreciation of the bee on the part of these particular fruit men, at least.—Ed.]

THE SUBJECT OF BULK COMB HONEY.

I do not want to give the impression that it is my intention to "harp continuously" on this subject; but there is a reason for taking up the matter at this time. I have learned during the last two years that my prediction (that bulk comb honey could be profitably produced in the North) was *not* wrong, as many claimed. Through many letters I have learned that bulk comb honey can be produced *and sold* in the North. It

was found by beekeepers, who tried it on a small scale at first, that they could sell all they could produce *right in their neighborhood, and to people who never cared to buy extracted honey or high-priced section honey.*

In this lies one of the greatest and most valuable arguments in favor of bulk-comb-honey production. The valuable point is in that it is possible to sell honey to people in many localities who do not buy the other kinds. This creates a new demand, and insures a larger consumption of honey by a larger number of people over a greater area. The result is a better distribution and less slump in the generally overcrowded honey markets.

Of course, I do not predict that bulk comb honey will replace other kinds to the extent it has in Texas; but when produced *with* the others, and disposed of in places where it will be taken, we do not doubt for a moment that a greater consumption of honey could be worked up, and that prices would be stiffened as a consequence.

COTTON HONEY.

There seems to be a great difference of opinion relative to the quality of cotton honey so much produced in the Southern States. According to the A B C and X Y Z of Bee Culture regarding its flavor, you add, "As a rule it must be used for manufacturing purposes;" and in speaking of its qualities we find this paragraph: "Cotton honey has the peculiarity, when confined, of bursting the receptacle in which it is held. Whether it ferments or generates gas has not been definitely determined. It can, however, be put into casks, providing there is plenty of air-space left to allow for expansion."

According to our experience we believe that this needs a little correction. But the difference in locality and in atmospheric conditions has a surprising effect on the nectar yield as well as upon the quality. Hence the experience of others differently situated may bring out information that will warrant leaving the statements about cotton honey unchanged in the A B C book. We have arrived at a definite conclusion, however, and would like to invite all the readers in the Southern States to write us concerning cotton as a honey plant, its character as a yielder of nectar, the color and quality of the honey, and its keeping qualities. We should like to know the extent of the yield of cotton honey obtained both in a single year and for a period of years—the supply, demand, and the price obtained.

I have under contemplation an extensive illustrated article on cotton as a honey plant; and before completing it I desire to know more about this subject in localities different from my own. It is hoped that many responses will arrive at an early date.

BEEKEEPING IN CALIFORNIA

P. C. CHADWICK, Redlands, Cal.

The automobile, without doubt, will largely take the place of the horse in apiary work; but old Dobbin will be found wending his way up the rough canyon roads and around the foot-hills for some time yet.

Hives should not stand in the shade in this country. There is a difference of from 25 to 45 degrees between the temperature of day and night, which makes the morning sun valuable in getting the bees warmed up and into the field as early as possible. I have fourteen colonies in my back yard, on which I do much of my experimenting and make observations. A part of them are under orange trees, and I find these much less active than those in the sun, except on very warm days.

Mr. J. K. Williamson, of this city, and widely known in the southern part of the State, has sold most of his bees and moved to Mendicino Co. Our local beemen will miss him much; for, besides the convenience of his little hive factory and excellence of his workmanship, he was much consulted on questions of bee management, for he is a close observer, with more than 40 years of experience, 23 of which were spent in Redlands. It is safe to guess that he will soon be in the business at his present location.

No longer does my mind feel akin to that of the "man from Missouri." I have been "shown." It rained long and hard, and doubtless much good will result; but, alas! too late, I fear, to result in the benefit many looked for; besides, it is the off year with the sages, and that, to my mind, is significant. My bees have little more brood than at this date a year ago, due to the long drouth followed by cold stormy weather. The redeeming feature is that I have a much better supply of old bees to support brood-rearing when the weather warms up.

Elias Fox, p. 180, Mar. 15, has taken exceptions to my comments on his bee hunting. He says he would like to live in a country where he could find nine bee trees while walking a distance of two miles, and that he would soon have the bees in hives, or destroyed if diseased. If he could get a permit from the government to cut the trees he could find on this one reserve that there would be a lifetime job ahead of him, and he might safely order a few hundred hives to begin with. Trees that are now sound would be decayed, and contain hollows large enough to hold bees before he got through. Eastern people have little idea of the number of wild bees in this country. Mr. J. D. Bixby, of Covina, Cal., told me of a man

who, having lost most of his bees, took, I think, 140 empty hives, put them up in trees, and caught 120 swarms in one season. In the season of 1905 I divided two strong colonies, that were ready to swarm, into eleven hives, giving each two frames of brood with a queen cell. Six of these gave me a full extracting before the season's close. I can make colonies cheaper than any man can chop them out of trees. It doesn't pay here.

Mr. A. F. Wagner, of El Centro, Cal., p. 144, March 1, has quoted only a part of my sentence on p. 89. Read the two following lines of my article. There seems to be some concern about my knowledge of the foul-brood law, for on p. 700, Nov. 15, Mr. T. O. Andrews says I made a made a very unwarranted attack on it. Now Mr. Wagner tells how the inspector is appointed and how he can be removed. However, here in San Bernardino Co. we have one of those non-removable kind, and we have tried in vain, with petitions, personal talks with the supervisors, and every available means, to get the politician out and a bee inspector in; but we have failed. Why? because the law is *weak* in allowing the office to be at the disposal of the supervisors instead of the beekeepers. A chain is no stronger than its weakest link, neither is a law. But so long as our county is cursed with an inspector such as we have I will continue to pound the law; and to those who desire, I will extend the privilege of pounding me.

If Mr. Wagner had been before the State Association, and heard the discussions on a resolution offered by Mr. Geo. L. Emerson, of Los Angeles, requesting the Board of Supervisors of San Bernardino Co. to remove the present inspector, he would doubtless have a different view of the law. Mr. Emerson's resolution passed without a dissenting voice. Mr. Wagner says, "Do we want the Governor to appoint our inspector?" By all means we do; but we want the beekeepers to have a say about whom he appoints—in short, leave the selection in the hands of the beekeepers, and the legalizing of the appointment with the Governor. Truly it is a condition and not a theory that is confronting us.

Cramps Caused by Eating Honey

Several of my friends like honey, but can not eat it, on account of cramps which it causes in the stomach. Is there any way to overcome this by treating the honey in some way? C. C. C.

[It is true that some persons can not eat honey; but cases of this kind are few and far between. Our impression is that the honey is not always to blame. However, some have suggested that they suffer no bad after-effects if they drink milk at the same time they eat the honey, or mix the honey and milk together.—ED.]

Conversations with Doolittle

At Borodino, New York

INCREASING COLONIES.

I have nineteen colonies now, and would like to increase to forty or more this year. Please tell me how to do it.

Kevil, Ky.

J. G. NANCE.

This inquiry is quite unique; for out of hundreds of letters I have received during the past ten years I have not had one of the kind; but I have received scores during that time asking how swarming could be prevented. The majority of beekeepers are looking more anxiously for a sure way to keep down increase, and more especially for something practical that requires only a little work which will do away with all desire to swarm on the part of our little pets.

[I recall that, during the season of 1873, I desired to increase twenty colonies of bees to forty, and to do it in such a way that I could at the same time get a good crop of comb honey. With this desire in mind I searched all the bee literature I could find in order to learn how I could best accomplish this; and, strange as it now seems, nearly all who mentioned this matter advised doing it by natural swarming. Nearly every writer claimed that, where only the first (or prime) swarm was allowed to issue, more honey could be obtained from the parent colony and the swarm than if no increase was allowed, as the new swarm would work with a vigor surpassing any thing that could be brought about through any non-swarming plan, or by any known means of "artificial increase;" and by using this best of all known ways, both for increase and a large yield of honey, colonies could be doubled each year, which should be enough to satisfy any reasonable person. And I concluded this was right, as, by doubling each year, my 20 colonies would reach the number of 640 in five years.

Now, if Bro. Nance is of the opinion that the best writers lived forty years ago, this plan will be just what he wants, as it will give him 38 colonies next fall, and "roll up a surplus crop greater than can be gotten in any other way." But the trouble with me was that not one colony out of my twenty would be satisfied with giving *only* the prime swarm. So the after-swarms kept issuing when I was in the hayfield, when I was at dinner, when I wanted to be at church, before breakfast, after supper, and, in the slang of to-day, "at almost any old time," until I found that the parent colony gave but little surplus. I tried all the plans given to stop after-swarming, but without success, till one night while lying awake (this lying awake nights and planning for the future is one of the symptoms of the bee fever), it came to me that no after-swarm ever issued without the piping of the first young queen that emerged from her cell; and if all queen cells were cut early the first morning after piping was heard at night, all after-swarming would be prevented. After this conclusion I soon fell asleep.

Waking refreshed, though not rid of that bee fever, I soon treated four colonies by shaking the bees from every comb in the hive and pinching every queen cell found in which I had heard piping the night before. I now watched operations. There were no further swarms, and the bees were working in the sections a week later better than new swarms would have done. This was what I practiced for the next twenty years, and I had an average yield of over 80 lbs. of comb honey from each old colony.

But Bro. Nance may prefer to have no natural swarms at all, as do the rest of us in this twentieth century; and if so, he will find the following plan of increase one of the best, detracting but little from the results of his non-swarming colonies:

When the colonies begin to grow strong in brood and bees, and before they contract the swarming fever, take two frames of emerging brood from any strong colony, or one frame from each of two colonies, putting them in an empty hive together with two frames partly filled with honey, having the two frames of brood between the frames of honey, and putting a dummy next to the comb on the vacant side of the hive. Before putting them in the empty hive, all bees should be shaken and brushed off in front of the hives from which they were taken, so that no queen will be taken from her colony. The space left vacant by thus taking these combs out is filled with frames of comb, if possible; if not, with frames of comb foundation. Now select another of the stronger colonies. Put a queen-excluder on it temporarily, and place on it the hive already prepared, having the two combs of emerging brood, which should be allowed to remain two or three hours, during which time the young bees will come up from below in sufficient numbers to care for the combs and brood.

After this the hive should be placed on the stand it is to occupy. Queens should have been previously reared, or purchased for these colonies, so that laying queens can be given them at dusk that night. A ripe queen cell will answer; but a week or more of time is lost where such cells are given. These colonies can now be built up in any way desired. I find that, if they are made a little in advance of the swarming season, as soon as the queen begins laying such colonies will build from two to four nice combs of the worker size of cells, if frames having starters are given them. But it is usually best to use frames filled with foundation. I have made colonies in this way with perfect success, clear up to the time of the blooming of buckwheat. There is no need of natural swarming for increase when we can make as many colonies as we desire in so easy a way. But such plans as these are made possible only through the advent of the queen-excluding metal.

General Correspondence

COMB FOUNDATION

What Weight to Use and How to Use it

BY R. F. HOLTERMANN

Opinions as to the use of comb foundation vary greatly. To one beekeeper its use at all is deemed an extravagance; another wants full sheets everywhere; and a third, after wrestling between his own sense of what is right and his innate penny-wise-and-pound-foolish tendencies, gives the bees in the brood chamber half a sheet of foundation.

To the beginner let me say that the beekeeper who uses foundation secures straight combs of worker cells which may be used for twenty years—a very important item; and the bees are saved at least a portion of the labor of producing wax and of the honey necessary to produce the wax, because honey is to the bee in the production of wax what grass is to the cow in the production of milk; and the secretion of wax is largely a voluntary act, and to that extent unnecessary.

In Canada it is safe to say that every beekeeper who wants to feel sure of straight combs uses at least starters in his frames. A starter is vastly better than no comb foundation at all; for it is natural for the bees to get their suggestion of worker comb from the nature of the cells above. It is true that bees in cell-building often turn from worker cells to drone; but it is seldom that a comb started *drone* is changed to worker. I am not now referring to worker combs which had a hole in them, which the bees filled with drone comb. Half-sheets of foundation tend more to encourage the building of drone comb than mere starters, probably because the worker bees get the start of the queen's laying, and turn to building comb for storage purposes which, in a fast flow, means drone comb. To me it has been amply demonstrated that when starters are used there is likely to be a larger proportion of worker cells in the brood chamber than when half-sheets are used. If your pocket-book is empty, therefore, use full sheets as far as you can, and then finish up with narrow starters rather than half-sheets.

THE EXTRACTING-SUPER.

For extracting-combs I always use full sheets of foundation, and these combs may then be used interchangeably with those in the brood chamber. There is not much of this shifting in our apiaries, yet occasionally the need is great. Again, there are occasions, if drone comb is absent in the brood chamber when the bees will prepare the drone cells in the supers for the queen, and will hold them for her to the exclusion of honey. Under such conditions there must be a lack of harmonious conditions in the hive, which more or less antagonizes the worker bees

toward the queen—a condition which it is not well to bring about.

WEIGHT OF FOUNDATION.

The proper weight of comb foundation to use is a matter upon which there is a great variety of opinions. The make of the foundation, the wax, the climate and temperature, and the conditions under which the foundation is used, such as the strength of the colony and number of bees which cling to the foundation, room and ventilation, the support the foundation receives, all have an effect upon the resisting power of the wax and the pressure brought to bear upon it. I use a grade half way between medium and light brood foundation, and I support the sheet by means of three horizontal strands. There are those who advocate vertical wiring. I have no quarrel with such; but, in passing, I want to say such wiring necessitates a thicker and stronger bottom bar than is generally used, or a substantial stay between the top and bottom bar; and this and the other "fixings" take much more time than is worth while for me. This season I expect to run over 10,000 super combs, and the horizontal wiring is all I care to undertake. Perhaps it may be well to state right here that probably no plan embraces all the advantages.

In wiring, let us remember that, without support, the greatest strain on the foundation is on that portion of the sheet nearest the top, and the wire should be placed accordingly. For instance, to put a wire at the bottom of the sheet only prevents the sheet from sagging at the bottom; and if it stretches at all, such a wire will cause it to buckle. The upper part of the foundation bearing the greatest weight should have the greatest support from the wires used.

HOW TO GET FOUNDATION DRAWN OUT.

A long thin sheet of comb foundation attached only at the top brings about a condition not found in nature. When the bees build comb they fasten it to the top. The sides are rounded, and the side walls of the cells are largely built out by the bees before the lower half of the comb is built. Then come the excitement and heat generated by the bees when they first cluster in the hive after swarming is over before they begin building comb. *Foundation* has to stand all these strains when the bees are hived on full sheets. The best place to draw out foundation, barring weak stocks, is in an extracting-super with a moderate honey flow, giving the bees partly drawn comb and the rest foundation. In drawing out foundation the frames should not be spread beyond the normal distance. Thus, in my twelve-frame super (for that is the hive I use), I put on one side five drawn combs, on the other side six sheets of foundation. Before this foundation is entirely built out or capped, one of the frames (now combs) is taken out, and the remaining

five combs spread to cover the space the six previously occupied; but the spreading should be done before the comb is capped.

If foundation has to be used with swarms the new swarm should be given an abundant entrance; and an entirely empty hive body under the true brood chamber is desirable for a few days. Then the hive should be shaded from the heat of the sun. At various times I have had comb foundation made from wax which came from South Africa. This, although testing chemically pure, lacked the needed strength. It appeared to me to have been damaged in rendering.

Brantford, Can.

EARLY BROOD-REARING

Conditions Affecting the Production of Seasonable Brood

BY LEO ELLIS GATELEY

It is a common belief that, the earlier in the spring colonies can be induced to start brood-rearing, the better they will be when the surplus season arrives. Early breeding, however, does not invariably produce such an effect; and under certain circumstances, because of vitality wasted in maintaining a brood temperature during cold weather, it frequently wears out three old bees for every new one produced. With the passing of winter on the other hand, possibly a dozen may be hatched for every one which is worn out. In view of this fact, undue stimulation of the queen at unnecessary times is a practice to be shunned.

Unless one knows just what he is going to do with the bees produced, it is impossible to have any fixed rules as to when breeding should begin. In cold weather a large amount of stores and vitality is expended in producing a small amount of brood. Moreover, bees reared in winter and early spring never live to see the main honey-flow. Any number, therefore, reared beyond the quantity required to replace those that are gradually dying off (unless needed for other purposes) will be produced at a dead loss. With a rather late flow it is certainly just as well to leave this matter to the bees. The beginner who is in doubt as to just what may be next on the calendar can, if his apiary is not in bad condition, do no better than to leave the question of early breeding entirely out of calculation.

In localities that permit of building up colonies to sufficient strength, so that increase can be made before the flow, or if bees are desired for some other equally obvious consideration, there should, with the advent of warm days, be little delay in brood-rearing activities. Conditions that permit of making considerable increase previous to the honey-flow are, perhaps, exceptional, but they exist here each spring. Again, with the exception of an exceedingly limited portion of the extreme south, a considerable percentage of the force of even healthy and prosperous colonies will usual-

ly perish during the winter from cold and old age. None of the colonies may be extra strong, and a few may be short of stores. If nearly out of stores, there will be practically no breeding done until nectar is found. When confronted by such situations the careful apiarist can sometimes do well to arouse the bees to the fact that summer is coming should they seem to be oversleeping any opportunities.

It is the colonies strong in bees and well supplied with honey that will be first to begin breeding in the spring. Of the several factors entering into the economical production of brood, the two mentioned above are unquestionably of the greatest import. The most superb example of early breeding ever coming under our observation was the case of a tall box hive of pure blacks purchased for a dollar last year. The whole front of this hive had been knocked out from top to bottom, not to speak of the cover, which consisted only of strips put on, in many places, an inch apart. The hive had passed through sun and rain during the entire winter, yet it was the strongest last spring of any colony we had ever seen at that season. A division was made in March, and in transferring the combs to a modern hive they were heavy with brood, and many drones were noticed that had been tolerated over winter. If colonies are strong and abundantly supplied with stores they will breed up in spring even under adverse circumstances.

With the coming of actual spring weather, backward colonies may be helped by the addition of young bees, and perhaps, still later, with brood. Or stimulative feeding may be practiced to advantage on days when the weather prevents the bees from foraging. The bees can also be made to move honey from one part of the hive to another by simply turning it end for end on the stand. The principal points in promoting brood production are bees, honey, warmth, a young and prolific queen; and, for fast work, a nectar and pollen supply.

Ft. Smith, Ark., Mar. 1.

SHORT COURSES IN BEEKEEPING AT MASSACHUSETTS AGRICULTURAL COLLEGE

The annual short course in beekeeping at the Massachusetts Agricultural College is offered from May 29 to June 13, 1912, to be concluded by a convention and field day. The course and convention are under the personal direction of Dr. Burton N. Gates, in charge of the apicultural service of the College and State.

The course includes lecture, laboratory, demonstrational, apiary, and field work, as well as excursions to large apiaries and queen-rearing plants. The concluding convention should bring together a hundred or more representative apiarists of the East, besides the noted authorities and commercial men who appear on the program.

The features of this convention will be lectures, demonstrations by authorities of

national reputation, as well as displays by inventors, manufacturers, supply merchants, and queen-rearers.

A special invitation is extended to all beekeepers to display and demonstrate inventions, implements, or methods. If table space is desired, or special equipment is to be prepared, notice should be sent to Dr. Burton N. Gates, Amherst, Mass., at least two or three weeks before the convention. The College will provide covered tables for the exhibit.

It may be found necessary to limit the number of students in the course, yet applications are accepted in the order in which they are received. No registration fees will be charged. Women are cordially invited to attend.

Registration with the Extension Service, Massachusetts Agricultural College, Amherst, Mass., is necessary for admission to classes.

CONVENTION PROGRAM.

June 12.

Morning, 9:00. Entomology building. Displays of manufacturers and queen-rearers.

9:15. Demonstrations. Improved flexible-plate foundation-fastener. Mr. A. H. Byard, West Chesterfield, N. H.

The Aspinwall hive. Demonstrator to be announced.

The remainder of the morning will be devoted to an excursion conducted by Director Brooks of the Experiment Station for the inspection of bee-forage crops. Leave entomology building at 10:00. (If possible the trip will include a visit to a North Amherst pasture where white clover has been brought in by top dressing.)

Afternoon, 2:00. Entomology building. Addresses. Bees in relation to fruit culture and plant life. Mr. A. W. Yates, Hartford, Ct.

Subject to be announced. Mr. R. H. Holmes, Shoreham, Vt.

Demonstrations. Electric foundation fastener and wire imbedder. Mr. H. F. Davis, Holyoke, Mass.

Inventions. Mr. F. Danzenbaker, Norfolk, Va.

Adjourn to the apiary. The features of the newly erected apiary building will be explained, including the general work shop, honey-room, box extracting room, bee-cellar, and equipment.

Demonstrations at apiary. Queen-rearing. Mr. F. M. Keith, Worcester, Mass. Demonstration of treatment of infectious bee diseases. State Inspector.

Evening, 7:30. Clark Hall. Address of welcome, by Pres. K. L. Butterfield.

Address by Hon. J. Lewis Ellsworth, Secretary State Board of Agriculture.

Illustrated lecture on the life, habits, and development of the honeybee, by Dr. James P. Porter, Dean of Clark College, Worcester, Mass.

June 13.

Morning, 9:00. Entomology building. Address. The progress of apiculture in the last two years, by Mr. E. R. Root, editor GLEANINGS IN BEE CULTURE, Medina, O.

Subject and speaker to be announced.

A few homely facts—things worth knowing how to do, by Mr. Arthur C. Miller, Providence, R. I.

Demonstrations. Mr. H. F. Davis, Holyoke, Mass. Electric honey-cutter for sectioning comb honey.

Demonstrations yet unannounced.

Afternoon, 2:00. Apiary. Demonstrations. Production of a swarm artificially, by Mr. E. R. Root.

Fuller queen-rearing system with completed outfit in operation, by Mr. O. F. Fuller, Blackstone, Mass.

Shook swarming, a method for the business or professional man, by Mr. H. F. Cary, Lyonsville, Mass.

Unannounced demonstrations.

REMOVING BEES FROM WALLS OF BUILDINGS, CREVICES IN ROCKS, ETC.

A Plan for Getting All the Bees, Including the Queen and the Honey, without Mutilating the Building.

BY GEO. W. RICH

A few years ago I read of a plan for taking a colony of bees out of a building without damaging the wall in any way. The idea was to place honey close by; and, when the bees were excited, a bee-escape was placed over the entrance, the supposition being that, because part of the bees were outside, the rest would come out to join them, so that, before long, nearly all the bees would come out. Then all that was necessary was to put them in a hive containing comb, some of which contained larvæ and brood. In a day or two the bee-escape could be removed and the bees would "rob" the honey from their old combs and store it in the hive.

This plan seemed very easy, and I was anxious to try it; but I never had an opportunity until I came to California, where I found many colonies of bees in the cliffs and rocks, in squirrel-holes, etc. I have removed thirty-five or forty colonies this winter, most of them from crevices in rocks. In some cases I have secured as much as 100 pounds of honey. This is often hard work, as some colonies are in places that are difficult to reach. But there is considerable excitement and fun attached to it, which I enjoy.

Sometimes the entrances to the cavities are two or three feet across, and often the combs are so far back that one can not reach them. To help out in such cases I prepared a framework out of half-inch lumber about 2x3 feet, having a hole in the center 5x7 inches. Around the outside of this frame I tacked burlap a foot or two wide so that, if the whole thing is set in front of the entrance, the cloth will fill up the space where bees might get in or out. With this in position the bees have to fly through the opening in the center. In a board that just fitted this opening I cut a hole 3½ inches in diameter, over which I tacked a funnel or cone made of wire cloth 3 inches high, the hole at the outer end being made with a pencil, so it is just large enough for one bee to escape at a time. An ordinary bee-escape will not do, as it shuts out the light.

A quart bottle containing honey and water (about equal parts of each), a hive filled with combs, one of which has some larvæ, brood, and a few bees, and a smoker, the fuel in which has been sprinkled with crude carbolic acid, completes the equipment. On some warm day, adjust the frame in the opening of the crevice containing the colony in such a position that the hole in the center is just about where the bees go in and out. Arrange the burlap around the outside so that no bees can pass in or out except through this entrance.

Can you find the queen?—Photo by H. C. Short, Winchester, O.

With the bottle, sprinkle a little honey and water inside the frame in order to start the bees, then put some on the outside. When they are working well outside, put the board containing the wire-cloth cone in place, and soon about a third of the colony will be outside. Then place the hive so that the entrance is close to the bees, and get them started in. When all are inside, take off the board containing the cone; throw more honey and water back as far as possible in the crevice, then put the cone back in position. By repeating in this way the second time, at least three-fourths of the colony will have come out; and, when they are all in the hive, fasten it up and take every thing away from the opening into the crevice. Light the smoker containing the carbolized fuel, and blow smoke as far back as possible, using a piece of hose in order to get the force of the smoke far enough back if necessary. In every case this will drive out the rest of the bees, including the queen; but she will not come out until most of the bees have left. As soon as the queen is in the hive, close the entrance to the crevice of the rock tightly to prevent any bees from getting in. In a

day or two open it again; and if a little honey is thrown inside, the bees will soon begin to carry all of the honey from the old combs into the hive.

Simi, Cal.

BEEES ON COMB PHOTOGRAPHED

BY H. C. SHORT

This photograph of bees on a comb was taken during the fall honey flow when every available cell was crowded with honey. Most of the bees ran around on the shaded side of the comb while the camera was being focused.

The queen found an empty cell and laid an egg in it while I was getting ready. I waited patiently, but she would not do it again. I shall try again next year and hope to have better success.

Winchester, O.

[We know by experience how difficult it is to get a good picture of bees on a comb, and we wish to say that our correspondent has done a splendid piece of work in producing this picture. Can you find the queen?—ED.]

An apiary of 11 colonies near Cincinnati that produced $2\frac{1}{2}$ barrels of honey last year.

BEEKEEPING AROUND CINCINNATI

BY REV. E. R. WAGNER

Cincinnati is no mean city, even if it is divided by rivers and an imaginary State line. We are not very far from the center of population of the United States nor from the center of the bee business. Here Mr. C. F. Muth originated his famous roof apiary. He loved bees so much that he kept them next to his sleeping-room. Hamilton, O., is just twenty miles away, where Rev. L. L. Langstroth lived, reasoned, experimented, and wrote; and sixty miles away his sacred ashes rest in Woodland Cemetery, Dayton.

In regard to bee forage, I believe we are most favorably situated. The many little valleys running into the Ohio River; the marshes, the steep hillsides, many covered with nectar-yielding trees, and at the same time yellow clover, sweet clover, white clover, smartweed, wild cucumber, etc., making our territory almost a paradise for the real lover of bees.

Cincinnati, O.

SWEET CLOVER ON WASTE LAND

BY HENRY REDDERT

Since the appearance of the article on the distribution of sweet-clover seed to the members of our association, Dec. 1, p. 726, I have received several inquiries from ranch-owners

in the West regarding the advisability of cultivating the land before sowing, and asking whether it grows on hard black land or sandy or hillside country. For the benefit of others interested, as I can not answer all personally, I submit the following:

Sweet clover will grow in almost any locality where there is plenty of sunshine and an occasional rain. Indeed, most of the sweet clover thriving around Cincinnati grows on the slopes of hills and on railroad banks, along creeks, on the dusty roadsides, and in every nook where no one ever thinks of planting any thing. Even among rocks, or the ledges of stone-quarries, sweet clover makes its appearance.

It needs no further cultivation before or after the seed is sown, providing the sowing is done after a shower of rain to give it the impetus to germinate. It should be sown in the fall of the year—in August or September. When the seed-pods become dry and open up, nature will do its work. The September winds spread it broadcast; and after once taking root it sows itself at a surprising rate on rocky hillsides. It will make its appearance the next year graded down to such an extent as to expose the yellow loam that would not nourish any other crop without fertilizer; and in spots where underbrush or trees have been cleared away it will be found blooming the next season.

Sweet clover is a hardy plant; and after once taking root it can stand a long drouth. During the hot summer days when in full

bloom, the thermometer ranging from 107 to 110 degrees in the sun, the hum of the bees when working on sweet clover sounds like an electric motor. Its roots will penetrate the ground to a depth of between 3 and 4 feet. Indeed, it is known to have cast its shaft 8 feet in order to get water.

SWEET CLOVER AN IMPORTED PLANT.

Fifty years ago progressive beekeepers of this city imported the seed from Europe, and sowed it on what was later known as Brown Street Hill. From here it spread over the entire Mill Creek Valley; thence to Kentucky and Indiana, and now we meet it wherever it has an opportunity to gain a foothold. Along country roads it grows close up to the wagon-tracks. It even seems to thrive on the dust stirred up by the travel on the highway. Along fences where the soil has never been touched by the plow or cultivator it forms a veritable hedge of snow-white flowers during full bloom. Who cultivated all this vast region? Only the hand of nature.

AS AN AGENCY IN SOIL FERTILIZATION.

If sown on cultivated land for a few years, and plowed under, it furnishes sufficient fertilization for other crops. The proof of this is seen on our hillsides, the soil being black from 15 to 18 inches. Wherever sweet clover has been abundant, this soil in most places is only the cover of some stone-quarry. Our farmers should try it in order to convince themselves.

AS FOOD FOR CATTLE.

When young it furnishes excellent food for cattle to browse on. No matter how often cut short before bloom, when the time comes it blooms just the same. This we observed along railroad lines, the men mowing it short in order to prevent its hanging over the tracks. It seems that sweet clover has not been appreciated as much as it should be, especially by our farmers; but the day will come when it will be recognized.

Cincinnati, O.

[From the way the various experiment stations are becoming interested, we believe the value of sweet clover is already recognized. —ED.]

HAND'S SWITCH BOTTOM-BOARD IN THE TREATMENT OF FOUL BROOD

BY J. B. HOLSINGER

I have been interested in bees from boyhood, and have kept a few colonies as a side line since 1875, partly as a means of obtaining outdoor exercise, having worked at a watch-maker's bench for over thirty years. In the fall of 1909 I discovered signs of American foul brood in some of the colonies. The following June I found three colonies that were affected. One was successfully treated by the Baldrige method, and the other two I shook on starters of foundation, and four days later gave full sheets, but the disease

Sweet clover in the valleys running into the Ohio River near Cincinnati.

J. B. Holsinger's apiary in the outskirts of Johnstown, Pa.

reappeared in the fall, and in the spring I found both colonies affected, and treated them as follows, from ideas I got from J. E. Hand and Geo. M. Steele.

On June 20 I set one colony on top of the other on one end of Hand's switch bottom-board, and took both queens away. On the other end of the switch bottom-board I placed a wood-and-zinc queen-excluder, and on this a hive with full sheets of foundation in frames. I then shifted the switch lever; and when a goodly number of bees were in the new hive I ran one of the queens in at the top and put two tubes, 8 inches long, back of the lever, with holes large enough for drones to pass; but they became clogged with drones that the bees were removing, so I removed the tubes and used a Porter bee-escape instead, which worked all right. I removed the queen-excluder from under the hive after four days, and soon had a powerful colony of bees in the new hive, with a good-sized swarm hanging out until I opened the side entrance. I am not sure, however, that the queen-excluder was necessary. Four days later I put on the first super, and a week later I put on a super that was well started by one of the colonies before treatment. This was rather risky; but as the honey-flow was good I think it is all right, as up to Oct. 20 there were no signs of disease. About 30 days after treatment I removed the diseased hive and used a little sulphur to destroy the few remaining bees, when the combs were destroyed and the frames boiled in a strong solution of concentrated lye and rinsed in hot water, which made them like new.

From this colony I took 153 well-filled sections of honey. I am so well pleased with the switch bottom-board that I expect to use it on each stand another season. I am aware that some make light of this use-

Super of honey taken off early in September.

ful invention; but if I can get rid of foul brood and still get a good crop of honey with so little manipulation, I shall be satisfied. I started in the spring with 16 colonies, and increased to 27. From 13 colonies I took 729 sections of honey as follows from each: 153, 70, 53, 53, 52, 50, 47, 47, 42, 30, 28, 27, 26. I keep my bees at the outskirts of the city, one mile by electric, and a half-mile walk brings me to them.

ROBBING OUT PARTLY FILLED SECTIONS.

I have been using a method for cleaning up partly filled sections that works very well and there is no danger of spreading disease. When the last super is removed, take out all good sections and put back on the same hive the super with the partly filled sections. In about a week after this, place a pepper-box feeder, containing half and half sugar and water, over the bee-escape hole. When the bees get nicely at work on the feeder, uncup the honey and move the feeder a little to one side. The bees will enter the super and remove the honey.

Johnstown, Pa.

AN ENTRANCE SHADE-BOARD

BY C. E. ADAMS

I am using a shade-board that I believe is a little better than any thing that has been described. It is shown in the accompanying engraving, the second hive from the front on the right having one in position over the entrance. It can be made of very light cheap stuff, and yet can not be blown away if it is firmly braced.

The covers on these hives belong to the winter cases, and they give excellent results as shade for the upper part of the hive.

Entrance shade-board used by C. E. Adams, Exeter, N. Y.

I have also a wintering device and feeder combined that has proven very handy. Two of them are shown on the box at the further end of the picture. A shallow tray holding about a quart of syrup is in the center of the box, and is surrounded by packing material. The whole thing is about the size of a ten-frame super, being 16x20 inches outside dimensions, and about 6 inches deep. With this protection over the brood-chamber in the spring I can feed earlier and with less bother than with any other feeder I have ever seen.

Exeter, N. H.

CHARACTERISTICS OF THE CROSSES BETWEEN ITALIANS AND CAUCASIANS

BY J. J. WILDER

In my previous article, page 455, August 1, I endeavored to show that Caucasian bees are not only equal to Italians as honey-gatherers, but that, under certain conditions, and at certain times, they are superior in this respect.

Caucasians are great propolizers, and they build considerable burr and brace comb, and for these reasons some feared that they would not be of much commercial value. Now, it is true that these are serious objections, and one could hardly be blamed for condemning the bees on this account. However, it occurred to me that, since the Italians do not propolize to any great extent, and build but little brace-comb, a cross might tend to eliminate these bad features. Black bees are not prolific enough to suit me, and the Italians are not satisfactory for several reasons. Hence I began crossing the Italians and Caucasians, and by selection succeeded in getting a strain that is far more satisfactory than either of the two races in their purity.

CHARACTERISTICS OF THE CROSSES.

As a rule, pure Italians do not build up fast enough in the early spring; and not until some nectar is coming in do they make rapid progress in rearing brood. Then if the honey-flow happens to be heavy and of short duration they are slow at storing. This is not true with the Caucasians and their crosses, for they spread brood rapidly in the spring, and keep the brood-nest compact besides, so that, by the time the honey-flow comes on, their hives are boiling over with bees ready for the harvest. They do not start off with a rush, and later become

M. D. Price among his 220 colonies, all in hives made of redwood lumber.

lazy, but they keep up in point of industry throughout the season.

My experience has been that, under severe test, while Italian bees disappear in great numbers, the Caucasians hold their own.

DO CAUCASIAN BEES BUILD UP TOO SOON IN THE SPRING?

Some have said that they do not want Caucasians because they build up so rapidly in the early spring and consume all their stores before the honey-flow which comes later. I have not found this to be true. In the late fall they follow the queen closely with honey, and, as a rule, they go into winter quarters much heavier than do the Italians. On this account they have ample stores next spring to last until the honey-flow.

CAUCASIANS DO NOT CAP THIN HONEY.

Here in the South we have a good deal of thin honey from various sources; and before it is thoroughly ripened the Italians cap it and then it begins to ferment, giving it a wet greasy appearance. This is not true of the Caucasians, for they keep such thin honey spread out in the comb, and they are very slow to cap it. When it is thoroughly ripened, however, and finished, it has a beautiful appearance and fine flavor, so that it brings the highest market prices.

ABOUT THE TENDENCY TO SWARM.

Mr. Frank Benton, the importer of the Caucasian bees, stated that they swarm con-

siderably, and the A. I. Root Company made the same statement after giving the bees a limited trial. But, if I mistake not, Mr. Benton explained that the cause of the excessive swarming is because they are so often kept in small hives in the country from which they came. I think this must have been true; for the first two or three years I kept these bees they would send out very small swarms, hardly worth hiving, except when several clusters went together. Such swarms came from very large colonies, too, from which much larger swarms were expected. Such small swarms were hardly missed from the parent colony, and the work in the supers was changed very little.

I have been trying to eliminate this inclination to swarm by breeding, but have not fully succeeded; for once in a great while they will swarm, although not enough to make necessary any of the usual preventives except providing ventilation and plenty of room.

The late R. W. Herlong, of Fort White, Florida, whom I referred to in my article on page 763, Dec. 15, as having had considerable experience with these bees, stated that he had had practically no swarming. Mr. W. F. Williamson, of Arabi, Ga., has a large Caucasian apiary, and has never had a swarm, although he has harvested good crops.

SOME MINOR POINTS OF SUPERIORITY.

These bees build more queen-cells, and larger ones. Their queens are more uniform in size. The bees are gentler than the aver-

age Italians. They always have plenty of drones. They are less inclined to rob. They supersede their queens readily and oftener. Fewer colonies become queenless. The colonies are more uniform in strength. They enter the supers more readily. Queenless colonies and nuclei accept queens from ripe cells more readily. The bees build up faster when it comes to dividing and making artificial increase.

Cordele, Ga.

A WESTERN APIARY IN WINTER QUARTERS

BY M. D. PRICE

On the front covers of GLEANINGS we have been having a number of views of eastern apiaries in winter quarters. I am sending you a view of my apiary in California that was taken two days before Christmas.

The large piles of frames are some old ones that I discarded. I bought my apiary of a party here whose hives were 18 inches long and 10 deep, so I got rid of them, for I wanted to use hives of Langstroth dimensions. These I like better in every way.

One of the views shows a cluster of manzanita. This commences to bloom the last week in December, and is valuable, because it allows the bees to breed up early. There is very little surplus from it; but the honey is water-white whenever there is enough to extract.

I have in my apiary 220 colonies which I handle all alone, except at extracting time.

I make all of my own hives and frames of redwood lumber, which does not rot as quickly as pine. Some of the hives that I bought were fifteen years old, and were as sound as a dollar, and yet had never been painted.

Arroyo Grande, Cal.

BEEES AS BUILDERS OF FLOWERS

The Part Bumblebees have Played in the Growing of Red Clover; How Bees Pollinate the Flowers

BY JOHN H. LOVELL

The English nation owes its power and wealth largely to bumblebees. This statement sounds a bit sensational, not to say improbable. But it was the opinion of a distinguished German scientist, Carl Vogt; and it is endorsed by one of the most eminent of living biologists, Ernst Hæckel, of Jena. Let us examine the evidence.

The red clover (*Trifolium pratense*) is chiefly pollinated by bumblebees, and is, therefore, called a bumblebee flower. The early settlers of New Zealand learned this to their cost. When they attempted to grow this valuable fodder plant, much to their astonishment it failed to produce seed. On inquiry it was learned that there were no bumblebees on those two large islands; but when about 100 of these bees were imported from Europe, the red clover soon became very fertile. Once introduced, the bumblebees multiplied apace, and a few years ago a letter appeared in one of the New Zealand

Typical California view, apiary of M. D. Price, Arroyo Grande, in the distance.

Manzanita blossoms which furnish honey for early brood-rearing.

papers complaining that they were becoming so numerous that they threatened to consume the nectar of all of the flowers and leave none for the domestic bee. The alarm, however, seems to have been groundless; for in 1905 the Canadian Department of Agriculture received a letter from the secretary of an agricultural association in New Zealand inquiring what species of *Bombus* pollinated the red clover in that country. Three kinds of bumblebees (*Bombus terrestris*, *B. hortorum*, and *B. hortorum* variety *Harrisellus*), descended from those imported in 1885, are stated to exist in New Zealand; but *B. terrestris*, the most abundant species, was regarded as unsuitable for clover pollination, owing to the shortness of its tongue. It was believed that the best results had not yet been obtained, and that it was desirable to introduce other and more suitable species.

According to Carl Vogt, one of the most important foundations of the wealth of England is found in the cattle, which feed principally upon red clover. "Englishmen," says Hæckel, "preserve their bodily and mental powers chiefly by making excellent meat—roast beef and beefsteak—their principal food. The English owe the superiority of their brains and minds over other nations to their excellent meat." There is no need to enter into any discussion here as to whether Hæckel's logic is sound or not, but it will hardly be denied that the production of this meat depends to a great extent upon the industrious bumblebee.

The dependence of the red clover upon bumblebees, either in this country or in Europe, is, however, not as complete as has

been assumed. It has been shown repeatedly in GLEANINGS that, under certain conditions, flowers are very freely visited by honeybees, and hundreds of pounds of red-clover honey are produced. Undoubtedly the most remarkable illustration ever recorded of the relation sustained by honeybees to the inflorescence of the red clover was given by E. R. Root in GLEANINGS for 1906, Aug. 1, p. 990. Near his north beeyard there were several fields of red clover. When the farmers began cutting these fields, the cutter-knives of the mowers stirred up a great number of bees, which so fiercely attacked both the horses and men that it looked as though they were not going to let anybody cut off their honey supply. At the same

time, a few miles away, near his south yard there was a big field of rank clover on which scarcely a bee was to be found. Here on clover fields only two miles apart the behavior of the bees was diametrically opposite. This is explained by a difference in the rainfall of the two localities. At the north yard there had been a drouth the whole season, and the corolla tubes of the red clover were so short that the nectar was readily accessible to the bees; but at the south yard there had been plentiful rains, and the tubes were so long that the bees could not reach the nectar. Pollination is also occasionally effected by other long-tongued bees, besides those mentioned, as well as by butterflies.

Incidentally it may be added that Darwin pointed out that the number of bumblebees in England was determined by the number of cats. Mice rob bumblebees' nests, and are in turn killed by cats; consequently if there are few cats there are many mice and few bumblebees. Here Professor Huxley suggested that, as old maids are fond of cats, and usually keep one or more of these animals as pets, it depended upon them whether there should be an abundant crop of red clover or not. It is certainly a curious instance of the intimate correlation of every part of nature.

Three other genera of very common bumblebee flowers may be found in almost any old-fashioned garden. They are the larkspurs (*Delphinium*), the aconites, or monkshoods (*Aconitum*), and the columbines (*Aquilegia*). They all agree in having the nectar concealed in long spurs, or nectaries, which vary in different species. The tongues of different species of bumblebees

likewise vary in length, ranging in the workers from $\frac{3}{16}$ to $\frac{1}{8}$ of an inch. In the females, or queens, the tongue is still longer, and in the garden bumblebee of Europe (*Bombus hortorum*) reaches the length of $\frac{1}{2}$ of an inch. Of our hardy perennials there are few which produce a more stately effect than the bee larkspur (*Delphinium elatum*) with its wandlike racemes of deep-blue flowers. The plant is a native of Europe, where it is pollinated by the female of the garden bumblebee, no other bee on the wing at the time it blooms having a tongue long enough to reach the nectar.

The aconites, or, as they are perhaps better known, the monkshoods, so called from the shape of the flower, are so dependent on bumblebees for pollination that this genus of plants is absent in those parts of the world where there are no bumblebees. For instance, there are no bumblebees in Africa, Arabia, Australia, or New Zealand, except those recently introduced, and in these regions there is no indigenous species of *Aconitum*.

I know of no plant cultivated for its flowers alone which manages to thrive and bloom so profusely under the most untoward conditions as the common garden columbine (*Aquilegia vulgaris*). The variously colored pendulous blossoms are great favorites with bumblebees, to which they are well adapted. Our wild columbine (*A. canadensis*) has scarlet flowers which are yellow inside, or rarely all over, and is often visited by hummingbirds as well as by bumblebees.

As pollinators of flowers, the bees, or *Anthophila* (flower-lovers), far surpass all other insects in importance. In their adaptations for collecting nectar and pollen, in diligence, and in their mental attributes, bees stand easily in the first rank. To them more than to any other insects is due the evolution of our flora. Unlike all other flower visitors they collect pollen, and it is this habit which has gained them their pre-eminence in the floral world. The beetles, flies, and butterflies take no thought for their young except to select a suitable place in which to lay their eggs. The solitary wasps provide their nests with flies, spiders, beetles, and other insects, which by stinging they have left paralyzed and helpless or dead; while the social wasps go a step further and masticate their prey before feeding it to their young. But bees are the only insects which feed their offspring with pollen; they are thus wholly dependent upon flowers, both for food for themselves and their brood.

As the result of this interdependence of bees and flowers, united with the industry and mental acuteness of the former, there have been developed a great company of bright-colored blossoms which are especially adapted to their visits, and are, in consequence, called "bee flowers." They agree in having the nectar deeply concealed, where it is inaccessible to ants and other pillagers. They are often irregular in form,

as in the pea, bean, and snapdragon. The object of these odd and sometimes bizarre forms is to compel the bee to pursue a fixed path to the nectar so that pollination may be effected with greater certainty. Finally they are more often blue than any other color. So dependent are many flowers upon the visits of bees that, in their absence, they fail to produce seed. Such are the red clover, salvia, larkspur, and some orchids.

Irregular or one-sided bee flowers occur in large numbers in the violet, pea, mint, and figwort families. The species of the violet family consist chiefly of bee flowers, the general form of which is familiar to every one. One warm clear day early in May I found the round-leaved yellow violet (*Viola rotundifolia*) blooming luxuriantly beneath an old beech tree. Bumblebees, as well as smaller bees belonging to the genera *Notomada* and *Andrena*, were flitting about busily from flower to flower. On the other hand, according to my observations our wild blue violets are very sparingly visited by bees, and are often infertile. Perhaps this is the reason why many of the species, besides their showy blossoms, produce small green flowers close to the roots, which never expand but are very fruitful.

CLEISTOGAMIC FLOWERS.

The beautiful and richly variegated varieties of the pansy (*Viola tricolor*) have been

A. F. Wagner, El Centro, Cal., pioneer bee-keeper and bee-inspector. Mr. Wagner began 26 years ago when a boy, and has worked with bees in various parts of the country. He now has 600 colonies divided into six yards.

One of the apiaries of A. F. Wagner, El Centro, Cal.

produced partly by selection and partly by hybridization. The corolla may be pure white, yellow, red, blue, purple, or black, or there may be manifold combinations of these hues. These striking diversities result from various mixtures and modifications of two pigments contained in the epidermis—violet-colored sap and yellow granules. In the pansy the spur at the base of the lower petal contains the nectar. The anthers lie close together, forming a cone, into the center of which is shed the dry pollen; and directly in front of this cone stands the stigma, on the lower side of which there is a flexible liplike projection. To reach the nectar a bee must run its tongue through the center of the cone of anthers; and when it is withdrawn the grains of pollen cling to its moistened surface, while the lip of the stigma bends it away so that self-pollination is prevented. But when the proboscis is inserted in another flower a portion of the pollen is lodged on a receptive part of the stigma where it soon germinates.

The pea, bean, clovers, vetch, locust, and a host of leguminous allies, are grouped together in the pea family, or *Papilionaceæ*—a name derived from the Greek word for butterfly, because of a fancied resemblance of the flowers to that insect. All of the 5000 described species appear to be bee flowers, though it is claimed that a few species are butterfly flowers, and at least thirteen species are known, which, in the absence of bees, are infertile. For the most part nine of the ten stamens unite to form a tube, at the bottom of which lies the nectar, if present. Four of the petals interlock around this tube, while the fifth, called the standard, is broad and erect, and brilliantly colored to attract the attention of insects (see a flower of the sweet pea). In order to obtain the nectar, a bee rests upon the two lateral wing petals, which act as levers, braces its head against the standard, when, if it is strong enough, the keel is depressed, and it

may introduce its tongue in an opening at the base of the staminal tube. In this family the pollen is applied to the under side of the bee's body in four different ways: It may escape through a valve, or it may be pumped out or brushed out, or there may be an explosive arrangement.

But what if it is not strong enough to depress the keel? Then it does not get the nectar. Notwithstanding their beautiful hues and honeylike perfume I have never seen the flowers of the sweet

pea (*Lathyrus odoratus*) visited by bees, and this is also essentially true of the garden pea (*Pisum sativum*). Why is this? So strongly are the petals locked together that none of our bees appear able to depress the keel and obtain the nectar. Doubtless in their transatlantic home (for neither species is endemic in America) there are bees strong to push open the flower. But as both of these bee flowers are easily self-pollinated they are very prolific, even in the absence of insects.

Many of the flowers of the pea family, in fading, undergo a change in position and color. In the white clover the white central flowers contrast with an older outer ring of rose-colored flowers. In the yellow clover the newer flowers contrast with a ring of chestnut brown. In the wild vetch (*Vicia cracca*) the older flowers bend downward and turn from violet blue to dark purple, while the purple flowers of *Desmodium* become green in withering. In this way the bees are enabled to determine the older, nectarless flowers which have been pollinated, from the young flowers which have not yet been visited.

In the mint family (*Labiataæ*) and figwort family (*Scrophulariaceæ*) the flowers are two-lipped, and often bear a crude resemblance to the heads of reptiles and other animals, as is indicated by such common names as snapdragon, turtlehead, dragonhead, painted cup, beardtongue, and monkey flower. Many of the larger flowers are pollinated exclusively by bees, not a few being bumblebee flowers; but fly flowers and hummingbird flowers also occur. In these families the pollen, in many species, is placed on the back of the insect and not on the under side.

The brilliantly flowered snapdragon is a bumblebee flower. So firmly are the lips closed together that the smaller bees can not force them apart, and thus the nectar is protected for the rightful guests. But as

the flowers grow older, the lips often part slightly, and then the smaller bees are able to force an entrance.

Another bumblebee flower is the turtlehead, which grows along the banks of streams and in marshes. The large white flowers rudely mimic the head of a turtle. Though I have watched them for many hours and on many different occasions, I have never observed them entered by any insect except bumblebees. Sometimes a wasp (*Philanthus solivagus*) will fly from blossom to blossom, examining the lips for nectar, but it does not possess sufficient intelligence to pass between them. The mouth of the flower is so small that a bumblebee sometimes finds difficulty in entering, and flies away to another flower with a larger opening; but once inside there is an abundance of room, and I have seen one of them turn completely around within the corolla. I once placed several flower clusters of the turtlehead in a glass of water a few feet in front of a hive; but of the many bees constantly coming and going, not one of them entered a flower. But presently, notwithstanding their unusual position, the bumblebees found them, and one of them visited every flower. Why did the honeybees almost completely ignore these blossoms, while the bumblebees paid them so much attention?

It will be remembered that, in the pea family, by means of various devices the pollen was placed on the under side of the bee's body; but in the mints and figworts it is deposited more frequently upon the back of the insect. In the turtlehead the four heart-shaped anthers lie well forward in the angle formed by the sides of the upper lip. Their inner faces are applied together to form a single chamber or cavity into which the pollen, when ripe, falls. The contiguous edges are densely woolly to protect the pollen and to prevent the relative displacement of the anthers by connecting the first pair above and the first and second pairs at the sides. When a bumblebee enters the flower it spreads apart the arched filaments opening the pollen receptacle and covering the thorax with fine dry grains of pollen.

The marvelous adaptations of flowers for effecting pollination, both by their variety and ingenuity, fill us with astonishment, and occasionally they surpass the bounds of the wildest imagination. The opening, maturity, and fading of the flower, the various movements of its organs, the allurements of color, odor, and nectar, and the behavior of the insect guests, which may number from one to two hundred, afford an endless field for observation. Flowers cease to be merely bright bits of color in the landscape when we know their life histories, their rivalries and tragedies; and—yes, their comedies we see as upon the stage reflections of our own experiences. There is no more fascinating study than entering the secret chambers of these bright-hued floral edifices which adorn our fields and gardens, probing the mysteries which there confront us. But we should seek the living blossoms.

"Each one of the beautiful flower faces," says Herman Mueller, "which we were wont to marvel at with a sad feeling of resignation as so many mysteries for ever veiled now looks upon us inspiring hope, and stimulates us in friendly wise to cheerful perseverance, as if it would say, 'Only venture to come to me, and in true love make yourself acquainted with me and all my conditions of life, as intimately as you may, and I am ready to let fall the veil that hides me, and trust myself and all my secrets to you.'"

Think of all these treasures,
Matchless works and pleasures,
Every one a marvel, more than thought can say;
Then think in what bright showers
We thicken fields and bowers,
And with what heaps of sweetness half-wanton May.
Think of the mossy forests
By the bee birds haunted,
And all those Amazonian plains, lone lying as enchanted.

But all bee flowers are not one-sided (*zygomorphous*). They may be funnel-formed, as in the gentians, or urn-shaped, as in the checkerberry, blueberry, and its allies, or even wheel-shaped, as in the common borage, or regularly spurred as in the garden columbine.

It is a remarkable fact that bee flowers are more often blue than any other color. Let us look at the colors of these flowers in the Northern States. Of 34 species of violets, 17 are blue, 4 blue-purple, 6 yellow, 7 white.

Of the 197 species belonging to the pea

Curt Lundgren, Stockholm, Sweden; eight months old; has never eaten common sugar. His diet has been oatmeal porridge and honey; and from his first hours his milk was diluted with honey. This is great talking evidence as to the nourishing quality in the honey.

Hartford, Ct.

ALEXANDER LUNDGREN.

family, 24 are blue, 88 blue-purple, 13 red, 33 yellow, 39 white. Of the 120 species of the mint family, 33 are blue, 47 blue-purple, 12 red, 4 yellow, 24 white. Of the 113 species of the figwort family, 28 are blue, 32 blue-purple, 7 red, 33 yellow, 13 white. As for the gentians, their blueness is proverbial, and has been well described by Bryant in his lines "To a Blue Gentian."

Blue, blue, as if the sky let fall
A flower from its cerulean wall.

On the other hand, neither bee nor blue flowers occur in the pink and rose families. In the immense orchis family, in which bee flowers are of comparatively rare occurrence, there is only one blue flower, *Vanda cœrulea*, of India. In this family red seems much easier to develop than blue. It should be added that, when two or more species of bee flowers, belonging to the same genus, blossom simultaneously in the same locality, they are frequently unlike in color, as red, white, and yellow in the clovers. This diversity of color facilitates the efforts of the bee to remain constant to one species.

If you ask me why bee flowers are so often blue, I shall be compelled to admit that I do not know with certainty. It is a problem that still awaits further study. Some naturalists say the bees prefer blue to every other color, while others claim that it is merely an incidental result correlated with the high specialization of the flower. For example, in the animal kingdom, white cats (if they have blue eyes) are nearly always deaf, but no one knows why.

Bee flowers are usually marked with spots or lines called "nectar guides," which point out the way to the nectar. In the snapdragon the palate is yellow; in the pickerelweed there are two bright-yellow spots on the middle lobe of the upper lip; in the turtlehead the white corolla has reddish lips. The flower of the hedge nettle (*Stachys erecta*) is yellowish white, with the border of the upper lip marked with two purple stripes, and the lower lip purple-spotted. The flower of the dead nettle (*Lamium album*) is large, white, or sometimes rose-colored, with the under lip pale yellow, marked with olive-colored dots; while the flowers of the hemp nettle (*Galeopsis tetrahit*), so common in waste places, is purple with a pathfinder on the lower lip of a yellow spot crossed by a network of red lines.

Finally, notwithstanding the industry and immense numbers of the honeybee, there are no flowers adapted to this species alone. Why should there be bumblebee flowers, but no honeybee flowers? Should we not rather expect the reverse? But on inquiry into the economy of the honeybee the reason is evident enough. Our domestic bee requires large quantities of stores, and in order to obtain them it must visit a great variety of flowers throughout the entire season. For this purpose a tongue of medium length is far more useful than a longer one. If the tongue is very long the nectar in open, wheelshaped flowers, like the strawberry and basswood, can be sucked

up only with difficulty and delay. To be sure, they would be able to obtain some nectar now inaccessible, as from bumblebee flowers like the red clover, or from moth flowers like the climbing honeysuckle, but this would not compensate for the disadvantages sustained. If a longer tongue would have been beneficial to the honeybee, Nature would have long since developed one. Apiarists can not improve on the tongue of the honeybee, nor can they produce a permanent strain of red-clover bees. Taken as a whole, and under all conditions, the tongue of the honeybee, as it exists, is much better adapted for the work to be done than any that can be produced by artificial selection. But there would seem to be no reason why a variety of red clover with shorter tubes should not be obtained by selection, if hybridizing with the forms with longer corollas can be prevented.

BEEKEEPING IN BULGARIA

BY NICHOLAS CHR. BARACKOFF

It is about nine years since I first became acquainted with GLEANINGS, and since that time it has been my guide-book on bees. I am pleased with it, not only because of its teaching in all branches of beekeeping, but because of "Our Homes," which gives me much encouragement in my Christian life.

I have endeavored to spread the use of the American Langstroth hive in our country; and, although I have run against considerable opposition, I think that this hive will soon be generally used. I also do what I can toward writing about American methods for publication; and I have translated much from GLEANINGS to encourage our beekeepers.

Dimitre Panteheff, Nicholas Chr. Barackoff,
Dolina-Bania, Bulgaria.

All Slavic states of the Balkan Peninsula in Europe have formed a Slavic beekeepers' association which has an annual meeting every year at different capital cities of the Slavic states. The first meeting was in 1910, at the capital city of Bulgaria. The second was in Serbia, at Belgrad; and the next one, which will be in 1912, is in Rus-

One of J. C. Dickinson's yards at Valdosta, Ga.

sia, at Moskow. Among the various Slavic states, Bulgaria takes the first place in beekeeping, because our beekeepers are always ready to learn.

In the photograph, the gentleman on the left is my teacher in beekeeping, Dimitre Pantcheff, and the other is myself. Mr. Pantcheff has 250 colonies in hives of the Dadant pattern, but he intends to change them to the American hive of Langstroth dimensions.

ITALIANS VS. BLACKS IN GEORGIA

BY J. C. DICKINSON

In the spring of 1909 I took a severe case of bee-fever, and cured it by buying 22 hives of black bees and transferring them to Danzenbaker hives. At this time I have 56 hives of blacks and 4 Italians, 3 of which I raised myself. I gave a frame of honey and \$1.00 to a man in the city for a frame of Italian brood; placed it in a strong queenless colony, and grafted part of the queen-cells on two other frames. I made a Danzenbaker hive into three apartments; carried it back to my city friend's Italian yard, with the result named above.

My Italians produced last season four or five times as much honey as the blacks in

the same yard, although the season was a failure from a financial point of view.

Valdosta, Ga.

BEEKEEPING IN THE CUMBERLAND MOUNTAINS OF KENTUCKY

BY J. S. JOHNSON

This mountainous region seems to be an ideal place for bees. There has never been a season in my recollection when the colonies have not made stores enough for winter, so it seems strange to me to read about those who have to feed for this purpose. It is true that we do not get a large surplus oftener than once in three years; but there is always some surplus each year.

The main sources of honey are blackberry, clover, sourwood, and goldenrod. Then we have a number of other plants and trees that furnish enough nectar for bees to build up on, such as blackgum, chestnut, fruit trees, black locust, and summer heartsease.

One or all of the flowers named above will furnish nectar for the bees each season. I have never known all of them to fail in one year, and so we have more chances for a crop than beekeepers in localities having only one or two resources.

I will give a brief description of last season. The fruit bloom yielded the last of April; and just as that was over, black lo-

Skunk caught in the apiary of Carl Vollmer, Columbus, Montana.

cust began to yield; then wild blackberries, which lasted until the clover season. In the meantime sourwood, chestnuts, and sumac lasted until the middle of July, making one continued flow from April 20 until July 15. From the middle of July until the middle of August we have a dearth. Then heartsease and goldenrod last until the frost comes. I forgot to mention poplar and basswood. The former is still plentiful in the mountains; but the latter is more rare, as many of the trees have been cut down, and the stock eat the second growth, so it is fast becoming extinct in some places. Where there are still virgin forests it still abounds, but it yields only about every fifth year. The stock care less for poplar.

There are no apiaries near me except those of farmers who keep a few colonies to furnish honey for their own use. The truth is, no one in these mountains knows any thing about the inside workings of a hive. I have always delighted in bees, but never had read any thing on the subject until one day I was looking over a government pamphlet on good roads, and saw in the index an address from which I could obtain some literature.

The study of bee culture has given me a new field of thought. It seemed to me when I had read these helps that I had been asleep thirty-five or forty years; but, coming at a late hour, I have the experiences of others to profit by. After I had skimmed the whole country for literature two years ago I began the bee business with two colonies of black bees in log hives.

I now have fifteen colonies in movable frames, all Italians except one, and all full of stores gathered from the kind of goldenrod that is spoken of in the A B C as being

very rare and having silver-like flowers. One colony stored 50 lbs. of surplus from this plant, and I took it off Dec. 25. For a description of this flower see page 666, Nov. 1. In 1910 and '11 the bees gathered sufficient honey to winter on, and good colonies gave a surplus of about 30 lbs. of comb honey. The honey is of a good quality and of a golden color. There is nothing where it grows that beats it.

There is a piece of land within a mile of my apiary that was cleared only a few years ago. It is situated up the creek in a hollow to the left. In order to go straight to the field a bee must fly over a mountain; but last fall the bees followed the creek until near the mouth of the hollow, and then turned to the left, making nearly a right angle. At one point on the route there was a small knoll; and if one stood on this knoll the laden bees would strike his hat. It seems that all the bees in the yard were going to this field. If it would pay to sow any thing for the bees it would be this plant. It will grow in any soil.

I make my own hives the standard size, with eight frames. I think they suit me best, from the fact that our climate in the mountains is more moderate than in similar latitudes, because the prevailing winds are broken.

Langnau, Ky., Jan. 25.

CAUGHT IN THE ACT.

BY CARL VOLLMER.

Early one morning last August I took a stroll through my apiary, and saw the tracks of some animal on some of the white-painted alighting-boards. Bending down to examine them more closely I was surprised to see the bees boiling out of the hive. I thought a rabbit might have hopped on the board and stirred up the bees, but wondered why he had selected such a place. Late that evening I was sitting on the porch of my cabin when I heard a scratching noise underneath. My first thought was pack-rats; but that could not be, because a large bullsnake had his camp under the house, and it would not be healthy for a mountain-

rat to make his home there. Without making any noise I reached for my rifle, and waited. Soon the digging started again, and in a few moments a sleek skunk emerged. I did not want to kill it right there, so I let it go a little way before I fired. Well, it was too dark to shoot, and I missed. The skunk started for his hole, but I headed him off. I guessed then what had been disturbing my bees, and so I set a trap in front of a hive.

The next morning I had not caught any thing; but on looking around I found tracks before some other hives. Borrowing some traps from a friend I set about half a dozen, and the other morning I found one trap sprung and a chicken leg in it. Poor biddy had gone there during the day, got caught, and the skunk had eaten her. I took up all the traps during the day and reset them at night, baiting one with the chicken leg, and in this trap I found the thief next morning. The bees in the hive were quiet; but when I got as close to the skunk with the camera as I dared he started to back up to the entrance of the hive, and the fight was on.

That fall I caught eleven skunks in front of the hives, and have had no trouble since. Skunks are easily caught, as there is no need of hiding the traps nor even baiting them, as one has to do for most other wild animals.

Columbus, Mont., July 1.

[Occasionally we hear reports of damage done by skunks. They seem to delight in scratching at the entrance, and then devouring the bees as they come out. It is seldom that any serious loss is noted, for the animals, as our correspondent states, are easily caught.—ED.]

A START WITH BEES ON A NEW JERSEY TRUCK FARM

A Detailed History of Some of the Mistakes Made the First Few Years

BY WILLARD B. KILLE

Beekeeping on a large scale is a business in itself; but I believe bees can, in a limited way, be made quite profitable on many farms where at present none are kept. Many are deterred from keeping bees simply through fear of being stung; others because they know nothing of the business, and hesitate to start.

Our first experience with bees was not exactly a pleasant one. Father, believing bees beneficial, and worthy of a place on the truck farm for the purpose of pollination, purchased a colony in an old box hive. It arrived at night. While sitting around the table before bedtime, two youngsters fired questions about bees faster than a whole corps of present-day bee-experts could answer them. Among other things we learned from a story told by the hired man that "natural beekeepers" could pick up bees barehanded, and that every colony had in

it one very remarkable bee called the queen, and that she was "boss" of them all. That night in bed we boys thrashed it over and decided that we were "natural beekeepers," and that our first business the next morning would be to capture that wonderful "lady bee," or queen, and display her to the rest of the family, thus demonstrating our prowess as beekeepers, and laying claim to our fitness for taking full charge of that colony as well as its future offspring.

Thus inspired we sallied forth the next morning to execute our well-made plans. Being older I volunteered to catch the bees in groups of five or six as they emerged, and to pass them to my brother, who was to examine them and locate the queen. But, alas for worthy motives and well-laid plans! I caught the bees. How many, I don't know—neither does my brother. He stopped neither to count nor console, but rushed pellmell to the house and hid well away from the bees, from my own howlings, and from mother's scoldings. It was a sad experience. That house held two wiser and more thoughtful boys. But it taught its lesson.

After that experience we felt perfectly willing to let father be beekeeper. We were interested at swarming time when he hived the new swarms in boxes similar to the old. We were also on hand with good appetites when any surplus honey was secured. However, the quantity was usually so small we felt but little sorrow when the bees got what my father called a "case of millers," and died, although at the time I failed to see why the bees did not drive the millers away by treating them as they did me.

The millers did good work—not one of father's colonies survived; yet there was no talk of securing more to replace them until about four years ago when all the bees in the neighborhood seemed to have contracted "the millers" and died. Then we noticed that our cantaloupes, watermelons, cucumbers, squashes, etc., were not setting fruit as they did formerly. We also observed that bees were seldom if ever seen working in the blossoms of these and other vegetables, while formerly the fields had been full. These facts made evident the necessity of having bees in the immediate neighborhood, so we determined to try again.

This time my brother, then in grammar school, having read in a farm paper that some people were making honey from the sale of honey, and also having partially forgotten his former experience, which was not as painful as my own, he determined to buy some bees; and to make them profitable, not only as pollinizers but as honey gatherers. He did not buy any, for our uncle, who had three colonies in box hives, presented him with a colony. This was placed on a stand of four bricks in an out-of-the-way place under a peach tree. Then he bored four holes down through the top of the hive and covered them with a weighted board. All was done on a cold day, when bees were not flying. He also made an 8×10-inch box. He

planned to remove the board covering the holes in the top of the hive as soon as honey began to come in, and place this 8×10 box over it to be filled with honey.

This was in the winter of 1907. My brother was a freshman in high school. I went to New Brunswick to take a short course in agriculture, and there something happened. We had special illustrated lectures on Saturday mornings. Two of these were on bees and beekeeping, and were delivered by Dr. D. Everett Lyon. Previous to this I had known in a general way that bees were sometimes kept in patent hives, and that there were a few people making a living from bees; but I had no idea of the size of the business nor of its vast possibilities. In fact, I had no knowledge at all of modern methods as practiced by our best beekeepers. To say that I was surprised at some of the statements and views during those two lectures would be putting it mildly. There were views of modern dovetailed hives filled with frames, and showing how they could be lifted out and examined while the bees were on them; neat supers to take the place of the old-fashioned top boxes filled with honey in one-pound sections—just the right size for table use; machines that would throw the honey from the combs, and leave it to be drawn off as a clear clean fluid free from wax particles; the different breeds of bees, and comparisons showing wherein the Italians were superior to the black bees; and also the buildings, hives, and apiaries containing hundreds of colonies of bees belonging to many successful beekeepers. These things were highly interesting, and I began to think of what might be done with my brother's colony, when some more views were shown illustrating bee demonstrations. The things those people did with bees was certainly marvelous. I considered that it would simply be suicide to attempt those things. To put it honestly, I fear I did not believe Dr. Lyon's statements concerning those demonstrations, even though he is, I believe, a minister of the gospel.

I came home in the spring, told my brother what I had seen and heard, and got him interested to the extent of sending for the A B C book. Father laughed at the idea of spending money for a book on bees; but when it came his ridicule was changed to wonderment that so much could be written about so small a thing as a bee. "Why," he said, in speaking of it to a neighbor, "it's a regular encyclopedia; and to think it's *all* about bees! Why, if those boys master all the things in that book they won't need to keep bees or farm either; they'll be scientists." We are not yet scientists, but that book was gone over and studied, especially by my brother, at every spare moment. So also was GLEANINGS, for which he soon subscribed.

When reading we found some things, in the light of our previous knowledge and experience, quite hard to believe. After making due allowance for exaggerated statements we still found that a surplus of 50 or

75 pounds of honey per colony was not considered a heavy yield at all; yet no one in our own neighborhood had ever seen such yields from box hives. Where was the fault? Was it the fault of the box hives, the bees, or the beekeeper? We determined to find out; if necessary, by experience. By making a start in a small way, there would be little to lose and much to gain in experience and knowledge if not in money; so an order was sent in for an eight-frame 1½-story hive suitable for comb honey. It was ordered nailed and painted, and was fitted with 4¼×4¼×1½ plain sections with foundation starters. An examination upon its arrival convinced us we did exactly right in ordering our first hive already nailed together, rather than purchasing in the flat and nailing the parts ourselves.

This was in the spring of 1908. My brother's colony in the box hive was in good condition. At his request I bought a half interest in that and we went into partnership.

When the trees began to bloom the bees flew out in constantly increasing numbers, and my brother expected to see a swarm each night on coming from school. We were all given special instructions to leave the swarm until afterschool for him to hive. Well, one hot day at noon out came the swarm—a big one too. It settled on a tree near the ground, and would have been quite easy to hive, but we left it as instructed. Our orders are now quite different. From that day they have been to hive swarms on the jump; for when he came home from school that night no bees were to be seen. Together we searched every tree, crack, and corner on the farm, but never located that swarm. It "lit out" for good.

Some days after our swarm left, our uncle had a swarm settle in a tree; and as he did not care to hive it himself, he gave it to us. The new hive was taken to the tree; and after much difficulty, but no stings, for we were as well protected as the average Egyptian mummy, the swarm was safely hived. But, alas! those bees had not been properly reared, and did not recognize the advantages of their new home fitted with all modern conveniences. They absconded without even leaving their next postoffice address. However they failed to pay for their night's lodging, so my brother and myself felt it to our best interests to locate them. We found them some distance away in another tree. The hiving process was repeated. This time they became permanent lodgers, and stood the trip home to our own yard successfully.

My brother's box hive cast a small after swarm that behaved better than the first, and was housed in a box hive. The bees in the box hives were left severely alone except for putting a top box on the parent hive. But we resolved that the work of the bees in the new hive should be watched, the bees themselves studied, and that we should learn to examine or manipulate them as outlined in the books.

The new hive was opened the first time with great fear and trembling. We had no

smoker, but no one could have been more completely covered and protected. Two thicknesses of mosquito netting around our faces, heavy coats and trousers with sleeves and legs tied down, and with thick hoghide gloves to protect our hands—even with such protection I am afraid I stood quite a distance away when the cover was removed; but after my brother had taken out a couple of frames without serious results I became more bold, and was soon as much interested in the work going on inside the hive as he. It was about three weeks since the swarm had been hived. The amount of work they had done was surprising; but the most interesting of all was to see with our own eyes the eggs, young bees, pollen, the life, the hustle, and other things that had before been pictured only in our mind's eye or on the pages of a bee book. This one glimpse of the workings of the bees inside their home more than repaid us for our work and the cost of the hive, but it did not stop there by any means.

Having survived to tell of one manipulation we found it a less hazardous undertaking to make the second, and it became increasingly less each time.

We found the heavy coats, trousers, and gloves unnecessary. A piece of netting was used over our heads so that an occasional jab might not make us unrepresentable for Sunday-school—that was all. On the second examination we were fortunate enough to get a glimpse of the queen; and after that we found the hitherto unbelievable feat of locating the queen not difficult at all.

In the fall, when we removed the upper story or super from that hive we had 24 sections of honey each, filled clear out to the edge. This wasn't like the yields we had read about, but we were pleased with it nevertheless. And, besides, it paid for our hive. We gave away four sections, and sold the rest for \$3.50. Our hive, together with expressage, cost \$3.25, so we gained 25 cents and some experience besides. The box hive gave us about 6 pounds of surplus honey. This was consumed at home. Altogether the year's experience strengthened our thirst for more knowledge on beekeeping lines, and demonstrated to our complete satisfaction the great advantage of having bees in frame hives rather than in the old-fashioned box hives.

The next year, 1910, we purchased in the spring five 1½-story hives in the flat; smoker, bee escape, and one Italian queen. This was followed in the fall by five more 1½-story hives, 100 sections, and 5 supers for use in 1911. All were paid for, however, in 1910, making a total of \$32.75 spent in bee supplies. The lessons we learned in beekeeping were valuable, and I presume they were practically the same as are common to every beginner. The fall inventory showed that we had six colonies of bees in frame hives (one of these Italians), and two in box hives. The honey yield, due to many causes, chief of which was our own blundering, was only 50 pounds. The highest from

any colony was 24 sections. We sold 41 sections and received \$7.17. This reduced our indebtedness to \$25.58, and we had five empty hives and sixteen supers for use the next season.

This year, 1911, was really the most interesting of all. Having an opportunity to secure seven colonies of bees in box hives at \$1.00 each we bought and actually transferred the bees from five of them to frame hives. We managed it so successfully that I no longer harbor any doubts as to the truthfulness of the statements Dr. Lyon made.

We had but one swarm, and that was in late summer, and was caused by not giving our Italian colony enough room. The queen we had purchased left with almost all the bees, and could not be located. It was a big loss, for we were expecting much from that colony; and its work earlier in the season justified our expectations. But, like many other experiences, it was needed to teach a lesson. The superior work of that one Italian colony, together with their gentleness, induced us to get more Italian queens. Eight were bought and introduced, but not all successfully. There were many experiments and blunders throughout the entire season, but in spite of the blunders we had honey too. One of our Italian colonies with a queen which was introduced in July gave a surplus of 75 pounds. With that as a starter we feel as though we might be able with more experience to get yields some time that will at least half way approach some of those we have read about.

Our expense this season for queens, box hives, and incidentals, was \$18.78, which, added to our indebtedness of \$25.58, left from 1911, made \$44.36. Our sales of honey and beeswax sold direct to consumers amounted to \$57.00. This leaves a balance of \$12.24 in money; and a present inventory shows that we have 11 colonies of bees in frame hives, 9 of them Italians; 3 colonies in box hives; all, with the exception of one box hive, going into winter in good shape, besides 16 supers, several sections, smoker, hive tools, etc., that have all been bought and paid for by the bees themselves.

No estimate can be placed on the value of work and study with the bees. It has all been done at odd times; and, speaking for myself, I can say that it has been a means of recreation and rest from the hustle and hurry that is essentially a part of every truck farm. For my brother in school it gives just the one thing needed to keep up an interest in things outside the schoolroom; and who knows but the bees may do their full share in paying his way through college? Stranger things have happened. However that may be, we have both developed a case of bee fever that refuses to be cured; and if we plan better things for the future it is because we have much faith in that future.

AN ABNORMAL QUEEN BEE

BY JAS. A. NELSON, PH. D.

I send you by this mail a queen. Very strangely, she is half queen and half drone. I have never seen such a queen, and I have never read of one. I will also send you the cell in which she was hatched. She was hatched in 18 days after the colony became queenless; but I do not know the age of the queen that produced her, at the time I took her from the hive. I was sick last June, and my domestic took away the frame to which the cell was attached. If it had been myself I would have written. It was on drone comb. I do not know what will be your explanation of such a thing. I have never seen a livelier queen.

REV. A. FRANCOIS, Dominica, B. W. I.

The queen referred to in this letter was sent to the Bureau of Entomology; and when received she was alive, and appeared to be in good condition. It was planned to introduce her into a colony to test her fertility, but she perished by an accident before this could be carried out. A careful examination of the exterior of the dead queen showed nothing abnormal or unusual in the structure of the head, thorax, or appendages.

The abdomen, however, was of a very unusual shape. Instead of the long tapering conical form characteristic of the normal queen (Fig. 1 D), it was in this case broadly ovate, as Figs. 1 A and C show. Moreover, the three last segments were bent strongly downward so that the outline of the abdomen suggests that of the drone, having a blunt apex, and doubtless was the cause of Father Francois' supposition that this bee was hermaphroditic (having both male and female reproductive organs). A more careful examination of the abdomen disclosed further abnormalities. In correlation with the unusual breadth of the abdomen, the sternites of the 5th and 6th segments are much broader than in the normal queen (Fig. 1 C). They are, moreover, somewhat asymmetrical, as is also the sternite of the 4th segment, although to a slighter degree. Most modified of all is the sternite of the 7th segment. In the normal queen (Fig. 1 B) this has approximately the outline of an isosceles triangle with a small notch at its posterior end. In the abnormal queen (Fig. 1 C)

this plate is so much reduced by shortening in the longitudinal axis that it is almost completely covered and concealed by the sternite of the 6th segment. This reduction of the 7th segment in part accounts for the strong downward bend of the abdomen. In addition the posterior notch is very wide and deep, with a semi-circular outline extending over fully half of the posterior border of the segment. The sting is also slightly abnormal, having a kink about midway of its length.

An examination of the internal organs showed other and more fundamental peculiarities. The poison-glands, poison-sac, and spermatheca (Fig. 2 A) in their size and structure display no apparent abnormalities. The spermatheca was empty, indicating that the queen was a virgin. The digestive tract also seemed to be normal. The sex organs, however, were strikingly modified. The left ovary (Figs. 2 B, OvD) was present, but flattened and bent into an S-shaped curve. Attached to its upper end was a conical opaque whitish mass (Ov) 1.8 mm. in length apparently representing a single egg-tube and seemingly

FIG. 1.—A, B, and C, dorsal, lateral, and ventral views of abdomen of abnormal queen; D, abdomen of normal queen, ventral view.

containing only a single egg. As Figs. 2 A and B show, the external openings of the poison apparatus on the one hand, and the spermatheca and vagina on the other, are

FIG. 2.—A, poison apparatus and sex organs of abnormal queen from above; B, ovary and oviduct of abnormal queen. AGID, duct of acid gland; BGI, alkaline gland; Ov, ovary; OvD, oviduct; PsnSc, poison-sac; PsnScD, duct of same; Spm, spermatheca; SpmD, duct of same.

very close together. In the normal queen this is not the case, since they are separated by a considerable interval which is taken up by the dorsal wall of the vagina. It is evident, therefore, in the case under consideration, that the vagina is very much shortened in correlation with the shortening of the sternite of the 7th abdominal segment.

The cause of the abnormalities recorded here is entirely unknown. The cell from which this queen emerged was, to all appearances, entirely normal. Moreover, these abnormalities can not be related to the sexual characters of the drone or the worker, except in so far as the reduction of the ovaries is peculiar to the worker, but in the latter case they are symmetrical. The queen is not in any way hermaphroditic, but merely abnormal in the reduction of certain parts of the abdominal wall and viscera.

Bureau of Entomology,
Washington, D. C.

[These abnormal cases are very interesting, to say the least, for they show that even nature sometimes apparently makes mistakes.

A short time ago we received a dead bee from one of our subscribers, which had all the appearances of an undersized drone. The head was clearly not that of a worker, the eyes being the exact shape of those of a drone. However, the bee had a sting, which, though it seemed to be rather small, was nevertheless a perfect sting with poison-sac and all.—ED.]

PROBLEMS IN CELLAR WINTERING

House Apiaries vs. Chaff Hives

BY DR. C. C. MILLER

C. H. Gebhardt asks some questions that I will answer without repeating them.

Your cellar, where the bees are, being some distance from their summer stands, toward spring, if the bees become too uneasy, you might set them out near the cellar for a cleansing flight, then return to the cellar till time to put on their summer stands, and no harm would come of it. But if you take them out, as you say, "once in a while," there would be more likelihood that some bees would go back to the location of the cellar when set on summer stands. Better give up the idea of "once in a while." Once is enough, and that toward spring, and not then if you can keep them at all contented in the cellar.

With winter-cases over hives you can not very well use Alexander feeders in spring. At that time it will be much better if you have saved over from the previous year combs of sealed honey, putting a comb near the brood nest, but never between two combs containing brood.

Your mating boxes containing four or five shallow extracting-frames ought to do fairly well to winter over queens in cellar, if each one is well stocked with honey and has a good force of bees.

I don't know whether your bees would fly three miles across the lake to reach those linden trees. If nothing was to be had elsewhere, they might, especially if the wind should come from that direction. I don't think you or I could smell basswood blossoms three miles away; but I suspect that bees are better smellers.

I don't know why it is that your bees did worse in your warmly built building than in chaff hives outside; but it is the usual experience, although some succeed with such buildings. I suspect, however, that the chief trouble is just because the house is so warmly built. When the temperature went down 25 degrees below zero it did not get so cold in the house as outside. On the other hand, when it went up above freezing, those same close walls kept it colder inside than outside. There was a more steady temperature in the house, making the house better in the colder times and worse when the weather moderated; and it is quite possible that the bees stand it better to be outside with the temperature ranging from 25 below to 40 above than to be in a house with the

temperature ranging from 15 below to 30 above.

You have ordered a tested queen for that queenless colony that has only two or three frames of bees; and the question is whether, by proper feeding and keeping warm, you can save it and get it strong for the harvest. May be. It is possible that it may give you the biggest yield of all your colonies. But it is a good deal more likely that neither bees nor queen will live to see the harvest. If that colony is queenless in March, most likely it was queenless long enough before it went into winter quarters so that all the bees are old, and will die off too rapidly in spite of any thing you may do. Nine times in ten—perhaps ninety-nine times in one hundred—the most profitable thing to do with a colony that goes queenless in fall or early spring is to break it up.

SOWING SWEET-CLOVER SEED

The Unhulled Germinates Just as Quickly as the Hulled if Sown Early

BY R. L. SNODGRASS

On page 730, Dec. 1, Frank Coverdale advises sowing sweet-clover seed any time during the summer between early spring, say April 1 and the last week in July. He also claims that unhulled clover does not come up as readily as the hulled. Now, I think if he will take some of the unhulled and hulled out of the same lot or sack, and plant it, he will find that it comes up just as readily as the hulled.

My experience has been that neither one will come up the first year in time to do well unless it is sown as early as February 1 or in March, so that it may freeze a few times before it is warm enough to germinate.

If the seed is put through a good sweat before planting, or if it is stacked before thrashing, and left long enough to go through a good sweat, it will germinate very well; but the safer plan is to sow about February 1, and not before; for if sown earlier there is danger of warm weather that may bring it up, and then hard continuous freezing, which will heave it out.

At this writing we have had several days of damp rainy weather, and any amount of sweet clover has come up from the seed, only to perish. This applies to both the white and yellow (biennial) varieties.

When I cut my crop of yellow-sweet-clover seed the weather was very dry, and at least 50 or 60 pounds of seed per acre was shattered out. I then plowed up this ten-acre field and sowed to buckwheat on the 8th of August; and now with all this sweet-clover seed turned under there could scarcely a plant be found that came up, and we had plenty of rain too.

I secured from this field 40 bushels of yellow biennial-sweet-clover seed, and later 75 bushels of buckwheat, which never does very well here, and especially on thin land.

Now, I think it a good plan to plow up a

field every other year, and sow to something else. Buckwheat can be planted; and after that, winter wheat can be put in, or oats in the spring; but don't seed too heavily, as it may smother the young sweet clover in the spring. By taking this precaution, the clover does much better, grows more rank, and a more even stand is obtained. After a good thick stand, one can not expect to have a seed crop the next season, as the seed crop smothers out all the young plants; consequently it is a good plan to put in something else in the spring or fall, for both a seed and bloom crop is impossible every year. If, by using the harrow, it would come up from the seed which scatters off in the fall, then we could have a seed crop every year, and it would not be necessary to plow it under so often, but it will not.

The yellow variety comes up much earlier than the white—about the 15th of June; and the seed that scatters off that early will not come up either. I think this proves plainly that the seed has to go through a "sweat" or freeze to cause it to germinate.

If Mr. Coverdale or any one else can tell me just how I can obtain a good stand and bloom crop every year I shall be very much obliged.

Augusta, Kansas.

FEEDER MADE OF FOUR MASON JARS

BY FRANK BAKER

I had to do some feeding last fall, so I devised a feeder which I like very well. I took a honey-board of $\frac{1}{2}$ -inch lumber 16x20 inches, the same size as the ten-frame hive, and cut four holes for Mason jars with perforated caps, either one or two quart. A good colony will take down four or five quarts in a night. A hive body should be set above the board to hold the jars in place, and to keep robbers away during the day.

Enid, Oklahoma.

Heads of Grain from Different Fields

Beekeeping in North-Central Texas

We find that that magic word "locality" has a wide and varied influence on bees and beekeeping in general. Texas is a large domain, if one will but stop to consider, with a great variety of climatic conditions. Here in the north-central part of the State we rarely have any honey-flow of much consequence until the cotton begins to bloom the latter part of June, thus giving ample time to beekeepers to get every thing in readiness for that longed-for period.

Our first pollen comes from what is locally known as swamp elm, which is now blooming, February 18. Then follows a variety of fruit bloom with wild plum, redbud, oak, alder, ash, and many other trees and vines, all furnishing more or less pollen, and some a small amount of nectar which serves to keep bees busy till the main flow begins; though seldom of late years, on account of the increased number of colonies in this locality, will this suffice to furnish enough for the necessary brood-rearing consequent on swarming. Feeding generally has to be resorted to for the best results.

However, our bees have wintered well this year, and are coming out with abundance of stores, although each colony seems a little short of bees, which probably accounts for the large amount of sealed stores on hand at present.

COTTON-SEED MEAL A SUBSTITUTE FOR POLLEN.

We farmers feed a great amount of cotton-seed meal to our stock. This is a bi-product of the cotton-seed oil-mills—a golden-yellow flour or meal resembling the natural pollen of many plants, and is rich in nitrogenous elements. During the last few warm days my bees have been literally swarming around the shed where this meal is kept, and are carrying away great loads to their hives. There is the usual abundance of old pollen in hives near the brood-nest, as was ascertained by an examination before they located this new find. I had never noticed this before, nor have I ever read of bees utilizing such a substitute for natural pollen; but I should think it a much better substitute than rye or wheat flour, as it is a much richer food—a chemical analysis showing the following: Protein, 48 per cent; fat, 7; crude fiber, 6; nitrogen, free extract, 24, while its fertilizing value is about as follows: Nitrogen, 7.5 per cent; phosphoric acid, 2.8; potash, 1.8. I see no reason why it should not become a comparatively cheap and valuable substitute for natural pollen in regions where there is a natural deficiency of this valuable adjunct to successful beekeeping.

Our honey in this section will, I think, compare favorably in color and quality with that of any other place, as we seldom have any amber honey, all being light, of good body, and of mild flavor. Our section honey won against all competition at the State fair at Dallas last season.

Another word as to locality. Last season I purchased, seven miles away, some bees in Danzenbaker hives with section supers. These, with scant attention, produced on one-inch starters over 100 lbs. of No. 1 white honey per colony, while my bees in the home yard, all of the same race of bees, with better attention, and run for bulk comb and extracted honey, averaged only about 25 lbs. Local showers at an opportune time is the only way I can account for this great difference, as the country is level and the honey flora is practically the same. Such experiences render beekeeping all the more fascinating, each succeeding season offering its new problems and ultimately rendering its valuable lessons.

Trenton, Texas, Feb. 18.

O. SAUNDERS.

Transferring from Box Hives Having Sloping Bottom-boards

I have a problem in transferring that I should like to submit. I have nine colonies in box hives that I wish to transfer in the spring into movable-frame hives; and instead of resting on loose horizontal bottom-boards at right angles to the hive bodies they have their bottom-boards nailed hard and fast at an angle of thirty or forty degrees above a horizontal plane, so that the bees, in going in and out, ascend and descend an inclined plane. The object of the maker of these hives in putting on this kind of bottom-board was to facilitate the re-

moval of wax-worms, dead bees, debris, etc., from the hives. The bottom-board on each of these hives extends three or four inches below the entrance to serve as an alighting-board. Two legs are nailed on the sides of each hive at the rear, so that the hive, when on a level surface, is supported in an upright position by these two legs and the lower end of the bottom-board. The tops or covers of these hives are rough boards nailed to the tops of the hive bodies, with small holes in them to allow the bees to go up into the upper story, or honey-box.

Now, the directions usually given for transferring require the old hive to be inverted and a swarming-box of the same size to be placed on top of it to receive the bees; but it is evident that these directions are not practical in the case of sloping-bottom hives such as I have described above. How would you proceed? I propose to drive the bees from the box hive into the frame hive through a closed passage or runway connecting the two hives—this passage to be a foot or two long, six or eight inches wide, and an inch or two deep—the bottom and sides to be of wood and the top of screen wire. The end which connects with the old hive should cover and inclose its entrance entirely, and be bee-tight—the other end to be inserted into the entrance of the new hive, which should be raised by cleats an inch or two above its bottom-board in order to receive this passageway.

To use this contrivance I would place the new hive on a table or bench fifteen or twenty feet from the stand of the old hive; then remove the old hive. Invert it and set it down close to the table on which the new hive is placed. After connecting the two hives by means of the runway or passage described above I would proceed to drive the bees out of the old hive. As soon as the queen and enough of the bees, say two-thirds, have gone into the new hive it should be removed to the stand formerly occupied by the old hive. I would set the latter close to and immediately behind the old hive, and connect the two by means of a passageway or gangway similar to the one used in transferring as already described. I would put a queen-excluder in this gangway in order to prevent the queen from going into the old hive. I should have stated that this gangway is to have a water-tight metal or wooden cover instead of screen wire, as in the case of the one used in transferring. By this arrangement the bees in the old hive can neither go out of nor into their hive without passing through the new hive; and the bees in both hives can pass freely from one hive to the other.

At the end of eighteen or twenty days I would place a bee-escape in the passageway between the two hives to prevent the bees from returning to the old hive; and if they are not all out of the old hive in 21 days I would smoke or drum them out, remove the old hive, and split it up into kindling—after having saved the combs, of course. Will this plan work or not?

Halls, Tenn., Jan. 9.

J. C. SAWYER.

[We believe you would find it much quicker to pry the cover from the box hive, put a box above it, and drum the bees up into it. It is not essential that the box hive be inverted, the only reason for doing it being that it is usually easier to do it than to remove the cover.—ED.]

Dead Bees in Front of Outdoor-wintered Colonies; the Mistake of Screening Bees in the Hive

Last fall I purchased two colonies of bees in what seemed to me to be old home-made hives which evidently had been used for a long time. The bees seem to be very lively, however; and after keeping them outdoors during the strenuous winter we have had I notice that every bright day about two dozen or more bees come out of the hives and freeze. I accordingly moved them into the stable, where the temperature is considerably warmer, placing the hives so they faced south, and put some wire fly-screen over the entrances to the hives. During the last week the bees have evidently been "cleaning house," and pushed out through the screen several teaspoonfuls daily of a substance resembling brown sand, and they have literally jammed each other up against the screen in their efforts to get out, so that about 25 or 50 seem to die each day. Thinking they might be

hungry I have given them a little syrup through the screen, although upon examination of the frames I found ample stores in the combs. Would you advise me to take the screen off the entrances of the hives and let the bees have access to the stable, and possibly fly out of the door if they wish? or would you recommend some other treatment?

Chicago, Ill.

C. F. CHILDS.

[During the winter you will always find some bees in front of the entrances of colonies wintered outdoors, even when they are wintering normally. However, during this past very severe winter it is possible that there were more dead bees coming out than was proper.

It was all right to take the hives and put them in the stable where there was less exposure; but it would have been better if you had taken them down into your cellar and darkened the windows so that the bees could not fly out. In any case it was a mistake to put wire cloth over the entrances, and we are a little fearful that it may have resulted in killing all the colonies. When bees are confined in a hive in this way it is almost sure to cause trouble. We advise you to remove the wire cloth at once; and it would be better for you to take the colonies down cellar and darken the windows, so as to keep them from flying out.—ED.]

Bees Flying from Six to Eight Miles

I quite agree with Mr. Doolittle in his theory that bees fly several miles in gathering nectar, but can go him one better, for I have traced my bees over six miles, and know they fed still further. I am well aware that a great many people think it is impossible to follow the flight of a bee; but it is a very easy matter at certain times—on a windy day, for instance.

The first time I discovered my bees working so far from home was by accident. I had been working at an out-apiary, and was returning home in the evening. When six miles from home I noticed hundreds of bees crossing the road on both sides, and was much surprised, knowing of no apiary in that neighborhood. In fact, this was in the tules, and there was no residence for miles around. We were having what we call one of our north winds, which blow here at times for three, six, or nine days. I was traveling facing the wind all the way home. The bees were returning home. The wind being very strong for them to fly against, they flew low and slowly. Being in their path of flight, as I was, and traveling in the same direction, it was an easy matter for me to trace them all the way home.

This was my first knowledge of bees going so far; but since then I have traced them a number of times for seven and even eight miles. Most authorities that I have read claim that bees travel only from one to two miles, which is only a theory, according to my experience.

Woodland, Cal.

L. B. CAPPS.

Six Questions

1. When bees are smoked, is the honey with which they gorge themselves lost, or do they replace it in the cells?

2. At how low a temperature in spring is it safe to open and manipulate the brood in the hive without chilling?

3. Is it all right to let the rays of the sun shine directly on the frame of brood and eggs when one is handling them?

4. What is enameled cloth?

5. I have heard it contended that the rendering of combs infected with foul brood is not necessarily done at a high enough temperature, nor the heat continued for a long enough time, to kill the germs, and disease may be spread by the use of foundation manufactured from wax thus carelessly rendered. Is there any thing in it?

6. How far back does foul brood date?

JAMES M. MUNRO.

Slate River, Ont., Can., Jan. 22.

[1. We believe it is not definitely known whether the honey with which the bees gorge themselves when they are smoked is consumed by them or replaced later in the cells. Some of it is undoubtedly consumed, but perhaps a part of it may also be deposited in the cells again. Probably it would depend on circumstances.

2. Opinions differ as to how low a temperature brood will stand for a short time; but it is safe to say that it is unwise to manipulate combs when it

is too cold for bees to fly, unless one or two from a hive are taken out for only a moment or two to make an examination—for instance, to determine the quantity of stores the hive contains.

3. It does no harm to let the sun shine directly on a frame of brood; but at the same time it wouldn't be good policy to leave such a comb exposed to the strong heat of the sun for any length of time on a hot day.

4. Enameled cloth is what is called table oilcloth in many localities.

5. Foul brood has never yet been traced to foundation made from foul-broody combs. There are plenty of other ways, however, in which it is known to spread, and spread rapidly. It does not seem impossible that wax rendered in a solar extractor, and made into sheets by the dipping process without being thoroughly heated, might transmit the disease; but the thorough boiling that the wax undergoes when properly rendered and then refined and sheeted in a modern foundation-factory surely kills all traces of the trouble.

6. It is not definitely known how far back foul brood dates. Some of the very old writers mention brood disease, and it is not unlikely that this was foul brood of one type or the other.—ED.]

The Best Feeder for Colonies in Buckeye Hives

1. For feeding weak stands in the spring, do you consider the Alexander feeder as good as any? Early in the spring, when the weather is cool some of the time, warm syrup can be poured into the feeder each evening without opening the hive and thus losing heat. I got 30 Buckeye hives with sealed covers last fall. I know the Doolittle feeder is recommended; but after the Alexander feeder is in position it seems to me it would be better for weak stands when there are strong ones in the same yard. The bottom-board of the Buckeye hive is 2 in. wide, or a trifle over. In order to use the Alexander feeder it should be 2 inches deep. How much syrup will it hold? and how will the feeder fit the Buckeye hive? I have been troubled sometimes by strong stands robbing weak ones; so I am a little afraid of the Boardman for weak stands.

2. It seems to me the Alexander plan for dividing is the surest and one of the best methods. Do you know of any better way?

3. Which side of the Buckeye bottom-board is better for summer? It looks as though the bees would be inconvenienced in trying to get up on the combs when the wide side is used.

4. Is the Japanese buckwheat as good as any for honey?

New Sharon, Ia.

FRED BRIGGS.

[We consider the Alexander feeder excellent for feeding weak colonies in the spring. One objection, however, is the difficulty of attaching it to the hive, especially the double-walled chaff hive or Buckeye hive. For such hives we recommend the Boardman feeder. There need be no trouble from robbers if you attach it properly. We use the Boardman feeder almost exclusively at Medina, and have no trouble from robbers. We prefer it to the Alexander feeder because it is easy to see when the syrup is gone, and it does not require any special change in the bottom-board or the hive. In cooler weather we use the Doolittle feeder because the bees will not take the feed out of the Boardman feeder after colder weather sets in. We would not advise you to try to use the Alexander feeder in connection with the Buckeye hive.

2. Yes, we consider the Alexander plan of forming increase most excellent. We do not know of any thing any better.

3. Some slight change was made in the Buckeye bottom-board of the hive after it was put out. We infer that you have the style that had the narrow entrance on one side and the wide entrance on the other. In winter, use the narrow entrance, and for summer use the deep one. The bees will have no trouble about reaching their combs. If you will watch them while they are flying heavily from the field you will find a lot of young bees hanging down from the bottom of the frames; and as the bees fly into the entrance they will fly clear through and alight on these bees.

4. With regard to buckwheat, we do not consider the Japanese quite the equal of the silverhull or the gray buckwheat for honey; but the Japanese gives a much larger kernel than either the silverhull or the gray. If you want honey we think you will prefer the silverhull.—ED.]

Bottom-board Adapted to Holding the Alexander Feeder

I have made thirty new bottom-boards to accommodate the Alexander feeders. I made the sides three inches wide and let them extend the width of an Alexander feeder back of the hive, with a notch cut out of the top of the side rail the thickness of the feeder. I made the back end piece the entire width of the side rails, and set the ends in the side rails the same depth that I plowed for the floor pieces. I did not halve in the cross-piece at the front, but made it as wide as the bottom of the side rail to the floor board, and set it back three inches from the front end so the nails would not be so apt to split the sides.

The beauty of a bottom-board of this style is, no matter how uneven the ground or foundation of the hive may be, it will always fit up to the hive bee-tight, so no robbers can possibly enter from the back end. The side rails of the common bottom-boards are all thicker than the feeder, and it is a lot of trouble to block the feeders up to fit the hive.

Ponca City, Okla. J. O. WILLIAMS.

Sciatic Rheumatism Cured by Bee Stings

In answer to your inquiry regarding the bee-sting cure for rheumatism, I would say that, previous to my commencing with bees, I was very much troubled with rheumatism and sciatica—so much so that I was for weeks at a time confined to the house. About twelve years ago I bought a few colonies of bees, not thinking, of course, that they were going to cure me of my trouble. But I, like most beginners, was stung a few times. But they never caused much swelling. However, after a time I began to miss my rheumatic and sciatic pains; and as I took GLEANINGS at that time I noticed that a French scientist had declared that he had cured some very bad cases of rheumatism. Then I saw several items in the *Canadian Bee Journal* regarding the sting cure, so I began to think that, perhaps, was the reason I was no longer troubled with rheumatic pains. Since I began keeping bees I have been troubled but very little with rheumatism. I never feel as well as when I am working among the bees and getting a few stings occasionally. My hands are drawn up from the effects of rheumatism; but the pain is all gone. I have come to believe that the acid in the sting neutralizes the uric acid in the blood, thus removing the pain. I have heard of several persons who have had the same experience as I, who believe the stings cured them.

Blyth, Ont., Feb. 21.

ALFRED B. CARR.

[While visiting the Ontario Agricultural College we had occasion to say before the students of the agricultural school that, in our opinion, the bee-sting cure for rheumatism had been greatly overestimated; that we thought, in the great majority of cases, it was of no benefit whatever. We conceded, however, that there were some cases where relief had been afforded. Mr. Alfred B. Carr, who was present, afterward came to us and stated that he belonged to the latter class. As his experience was quite remarkable we asked him to write it up, which he did as given above.—ED.]

Wintering Bees in Chaff Hives

My bees had a fine flight Feb. 20—the first since Dec. 12. They are wintering nicely. The weather during January and up to Feb. 20 has been very cold. The thermometer has several times registered from 20 to 30° below zero.

I have 110 chaff hives, all well packed and warm. I use a piece of old wool carpet over the frames. I

then fold three bran-sacks over the carpet. On top of this I place a bran-sack containing a bushel of chaff or dry sawdust. The wool carpet absorbs the moisture better than any cotton material. I find that bees, as well as people, like the warmth of woolen blankets during cold weather.

The main thing in wintering bees in chaff hives is to keep them very warm on top. I close the entrance, except a space 2 inches long by $\frac{3}{8}$ wide. There has been a good deal said about the extra expense of chaff hives. The difference between a single-walled and a chaff hive is only 30 cts. I have chaff hives that have stood on the same spot for 30 years. Why fuss with paper, and build clamps, when 30 cents extra will buy a chaff hive that will last a lifetime? My bees are blacks and hybrids. Sixty pounds of comb honey per hive has been my average yield year after year.

Fair Haven, Vt., Feb. 22.

I. N. HOWARD.

Questions from a Beginner

1. Are Italians as apt to rob as blacks?
2. Which is better—to jar bees off the frame or brush them off?
3. Will there be any brood in the hive 21 days after the first swarm is cast? If not, wouldn't this be a good time to transfer?

Huntley, Ont., March 19.

CAMERON BLACK.

[1. It depends more on the individual colony than upon the strain of bees or the race; but on an average we suppose Italians are a little more likely to rob than the blacks. However, this is not because of any greater desire on their part to get honey for nothing, but because of the fact that they are more industrious than the blacks, as a rule.

2. It depends altogether upon circumstances as to whether it is better to jar or brush bees from a comb. Briefly, we may say that a combination of the two plans is often the best. It irritates bees much less to jar them off; and the best plan, therefore, is to shake off all you can and then brush the few bees remaining. Some bees are much harder to dislodge from the combs than others. Italians cling tighter than blacks, for instance. Of course, there are certain times when fresh honey is being brought in when it does not do to shake the combs very much, for that would spill the green honey over every thing.

3. It depends on circumstances as to whether you would find brood in the parent colony 21 days after the prime swarm issues. If for any reason the swarm had been delayed till the young queens were practically ready to hatch, one of these young virgins might be mated by the seventh or eighth day following the issuing of the swarm, and would be laying within two or three days afterward.—ED.]

A Sweet-clover Crank

My hive-stands rest on posts two feet high, so as to be above the high-water mark. I live on the bank of the river, and two years ago I lost most of my bees by high water.

I am called a "sweet-clover crank" by my neighbors; but some of them are coming to my way of thinking. I have about one-fourth acre of white sweet clover, and I find that my horse and cow eat it as readily as any other grass. This season I am going to experiment cutting it for hay. Last fall, when the seed was ripe, I felled out about a bushel of seed and gave it to my neighbor. He has a stony pasture of about fifteen acres which he sowed with the seed I gave him.

I believe sweet clover will soon take the place of alfalfa. To insure a good stand I sow oats with it. Of course, different soils and different localities may make a difference.

Wakarusa, Kan.

M. E. MCFADDEN.

More than One Hive Needed on the Scales to Indicate What is Being Done

I note in *Stray Straws*, p. 98, Feb. 15, your answer to Dr. C. C. Miller, where you speak of a scale *hive*. I found out long ago that one hive on a scale is not sufficient to indicate accurately an apiary's losses and gains, as different colonies vary so much when gathering honey, when apparently just as strong. I used to have two colonies on scales. Of late years I have four. I made one for the purpose, which cost about \$5.00, and I find it very satisfactory. I can tell accurately the gain or loss of the apiary. I record the weight each evening when interested.

Williamsburg, Ia.

M. W. HARRINGTON.

Japanese Buckwheat Not Good for Honey

In your buckwheat booklet be very careful not to give Japanese buckwheat too much praise, especially as a producer of honey, it being practically worthless for nectar—here at least. We do not get a good crop of honey from it one year in ten. It frequently gives very large yields of grain, and just about as frequently none; and I have never yet seen such crops of Japanese buckwheat as I used to see when the gray and silverhull were sown, and when you could not get bees enough to gather the nectar. We once had an average of 70 lbs. per colony of section honey and winter stores in a total run of 14 days; but we are extremely lucky to get even winter stores from Japanese now.

BUCKWHEAT NECTAR SECRETION.

Buckwheat does not ordinarily secrete nectar after 11 A.M. Up to that hour honey is seen glistening in the five open nectaries of the bloom. After that time of day, unless a light afternoon shower, followed by murky atmosphere, intervenes (when occasionally nectar is again secreted and the bees go to work), the bees gather but little or no honey.

After once eating pure well-cured buckwheat comb honey, three-fourths of my private customers will have no other, and can not be induced to eat either clover or basswood. It must be well ripened, however. Buckwheat honey has a poor standing in the market, probably because it looks dark, while the demand is constantly increasing from educated honey-eaters. I have made, in the past, two shipments of buckwheat honey as far west as Kansas City, Mo., and generally can not nearly supply the demand.

Frenchtown, N. J., Jan. 18. W. W. CASE.

Value of Buckwheat, Both as a Honey-plant and for Flour

I think that buckwheat is a good paying crop. I sow a small patch every year. I had out about two acres last year, and got enough so that I sold 1250 pounds of flour at 4 cts. a pound, and had plenty for our own use. I used the bran for my cows. It is a very good feed for dairy cows. My bees, too, made a good supply of winter stores, and some surplus for us to eat on our cakes. I sold all of this flour at retail in 25-lb. sacks to my neighbors, and I also sell them some honey once in a while. I sow buckwheat early in the spring in order to plow it under for a fertilizer. It is good for the soil, and I get some honey from it. The buckwheat that I plant for seed is sown the first week in July. I have tried it earlier, but it does not seem to fill when the weather is too warm.

There are none of the ordinary prepared mixtures that will take the place of the real old-fashioned buckwheat cakes for me, and I think there are a great many others who would feel the same way if they were taught what the real thing is; but we must tell them in some way how good these things are, in order to sell our buckwheat and honey.

Lake Cicott, Ind. THOS. C. JOHNSON.

The Papaya, or "Pawpaw," of the South, etc.

Mr. A. I. Root:—I am glad to see that you like mangoes and guavas, and the other tropical fruits. As I was born and lived in British Burma until about ten years ago (I am now 22), I can appreciate your feelings over a good mango. I wonder if you have ever eaten the papaya, or pawpaw. The fruit varies in quality somewhat, but a good one is good. I will send you a few seeds of it from Burma. It fruits under a year old.

Savannah, Ga., March 20. CHAS. E. A. HALE.

[Our older readers will recall that I have several times written up the tropical tree that bears luscious "mushmelons." Those we have here, however, do not often fruit inside of a year, and I am going to take great pains with the seed so kindly sent from British Burma. These trees bear fruit every month in the year, and the fruit is a celebrated remedy for indigestion.—A. I. R.]

Form for Holding the Frame when Wiring

As I have never seen nor heard of any one wiring frames as I do I will try to tell how I do it.

I use a box or table just high enough for a work-bench, and take a board about an inch larger than the frames I intend to wire. I lay one side of this

board on the bench, place something under the other side, so that it will be about two or three inches higher, and then nail it solid. I then get a board one inch thick and saw it the size of the inside of the frame, and nail it on the board I have already nailed down. I put a frame over it and let the frame down until the holes in the frame are just a little above the inside board; then get a strip just large enough to fill the space between the frame and the bottom board (the one that is standing sideways on the box). These are then nailed to the bottom board. I fix a place for the spool of wire about a foot from the bottom board, and nail a small staple near the first hole in the frame, but far enough away so that I can drive the tack in after I have my frame wired. I am then ready to begin wiring. By having the board on the inside of the frame, and cut to fit, it holds the frame solid and square.

J. W. HOSIER.

Groove-and-wedge Top Bar All Right

I frequently notice in the bee papers that the wedge-and-groove top bar is condemned. Now, I use that kind of bar, and I think it is the best that is now before the beekeepers if made right. That is where the trouble lies. Some manufacturers make the wedge too small for the groove, and some of the wedges about right for half their length, then begin to taper off to a point. Out of some lots we have had to throw away one-third of the wedges and fasten the foundation with wax. All wedge-and-groove top bars, if made right, work to perfection if directions are followed. The Madary top bar is no good in this locality. If the foundation is not drawn out at once it will shrink and let the foundation fall down.

Turkeys and Ducks Eat Bees

On page 118, Feb. 15, Stephen Anthony makes the statement that turkeys and ducks never eat bees. I beg to differ here, as I had a hive of bees and some ducks in the same yard several years ago, and the bees *did* get eaten by the ducks—so much, in fact, that I had no more bees at the end of the year than I started with in the spring. Several of the ducks would stand in front of the hives and eat the bees. I do not know whether all of them did or not.

Monaca, Pa., Feb. 23.

CHARLES P. BLAIR.

Reversible Frame

The illustration shows my son's (Alex. Crisler) reversible frame. The metal strap is supposed to have a hole near the top, and a corresponding lug on the end bar to hold it in place. It can be used

on any frame of Langstroth size. The strap would be better if made of thin steel; but heavy galvanized iron would answer.

Walton, Ky.

Poultry Department

A. I. Root.

In all thy ways acknowledge him and he shall direct thy paths.—PROV. 3:6.

After the boys had taken four of my ducks, as I have explained, I was obliged to decide if the ducks loose in the main canal; but as soon as I tried shutting them up, the eggs began to drop off. In order to get the benefit of the canal, Wesley and I constructed a fence along the margin of the stream, setting the posts in the rocky bottom. This was possible because there are quite a number of live-oak trees along the margin of the stream that reach out over it. We set the posts near where one of these trees bent over the stream or had overhanging branches. With a crowbar we made a small cavity in the rocky bottom, and then spiked the post to the trunk of the tree or the limbs above. Then by stretching barbed wire and poultry netting on these posts we had a stream, perhaps five to ten feet wide and about one hundred feet in length. Now, when the ducks had access to the full width of the canal it required much less feed, as I have already explained. We concluded that what could not be *cured* must be *endured*. This time the boys have not as yet come on to our premises; but my last and only drake was lost, as I have previously explained, after we had constructed this fence in the creek. The boys broke through the poultry netting and barbed wire and killed my duck as I explained. Now, although I have had many difficulties and perplexities in my life-work, I have also had many surprises, or, if you choose, answers to prayers. A great many times when these prayers are answered I find much *more* has been given me than I asked for or expected. Let me explain how it is in this case. After the boys were arrested I found that I was once more at liberty to let my ducks out into the open canal. I then said to Wesley, "There! we have gone to the expense and trouble of making that wire-cloth fence along the canal, when at present we do not need it," and it stood for some little time unused. When my first incubator brood of ducks got about eight weeks old I felt sure that it would be very much to their benefit, and lessen the amount of food, if they could have access in like manner to the water in the canal. Let me explain that the best authorities on ducks have decided that it is not advisable to let ducklings out into the open water before they are four or five weeks old, or old enough to have some of the real

feathers that take the place of the down that is on them at first.

When six weeks old they are almost fully grown. I felt sure that they wanted water in order to do their best. Now, ducks or especially ducklings need only a very small yard if they have access to water. One day I said to Wesley, "Why, look here; we have got the nicest yard for the ducklings in the world if we just put some fencing across that strip we prepared for the big ducks. In a very short time we had it all fixed. The first day that they had access to this water amply repaid me for all the time and trouble it had caused; and just a few days later we fixed another similar place for the four-weeks-old ducks. See B and D in the diagram. Now about this strip of fence we put along the margin of the stream, about 100 feet long. The young ducks, each brood, have between forty and fifty feet for a swimming-yard. When I let them out of the house in the morning it would do *anybody* good to see the ducks go down into the water. They fairly make the water fly as they go from one end to the other of their yard. The amount of feed needed is also very much less. I can hardly explain this, for it hardly seems possible that they could get a *very* large amount of food out of the running water in this narrow strip. The improvement in their appearance and progress was very marked at once. In fact, after they had been out in this water several days they hardly looked like the same fowls. I will have to explain to you that the salt water at high tide rises up into this water, and I verily believe that a little salt water mixed with fresh water is a benefit to ducks and ducklings. They seem to enjoy it very

DIAGRAM OF OUR DUCK YARDS BORDERING THE DRAINAGE CANAL.

A, trap-door to admit laying stock into the stream. B, second trap-door, opening into outer canal. C and D, partition fence of netting. E and F, gateway for ducklings. G, duck house for young ducklings.

much indeed. Now, instead of this fence made along the bed of the stream at some little expense being money *wasted*, it is really one of the best investments I ever made. In connection with the above I want to tell you about another thing that I think I can call one of my "discoveries." Anybody who has had much to do with ducks and chickens, or especially with a brood from the incubator, has discovered how difficult

it is to get them to go into their house when a storm is coming up or you want to get them in for the night. By the way, I might mention that the only safe way, so far as my experience goes, for either ducks or chickens, is to shut them up every night at the approach of dusk and let them out again every morning, and I really enjoy doing this. The happiest time in the whole twenty-four hours is in the morning just at daylight, or a little before daylight, when I let my fowls loose and see them happy and rejoicing. In the morning is the time when domestic animals, after their own particular fashion, "praise God from whom all blessings flow," and I think we ought to follow them in this respect. Now to get back to our subject.

Many of you have found how difficult it is to get ducks or chickens into the coop at night, especially when the coop is in the middle of the yard. It is particularly so when you want to give them a little *larger* domicile because of their growth. If your brooder or your duck-house is in the *middle* of the yard you will find it a big job indeed to get them to go in, especially if a thunder storm is coming up suddenly. If you place it up against the fence at one side, you have a *better* chance; but then they will persist in running around behind it instead of going in. If you put it up in one corner it is still better. But even then they will wedge in between the wire-cloth fence and the side of the house, or get behind it or get into the corner. Now, at F and G in the diagram I have explained how we manage it. Instead of putting the brooder or the duck house in the yard, put it outside entirely, the door to it being in the corner of the yard. A better way is to attach the poultry-netting to *one side* of the duck-house and also the same on the opposite side.

If you drive your brood of chickens or ducklings up into the corner they have got to go in the door. A better arrangement still is to have the fence where I have placed the dotted line near G. In this arrangement you have a sort of lane like the letter V, and the building is right at the small end of this lane. There are few things that have given me more pleasure than this arrangement to get my ducks to go in when I am in a hurry. Just another thing about getting them to go into their house, especially if the house is a new one, in order to give them more room. Ducks, more especially the Indian Runners, have a habit of carrying their heads high; and, unless you have their doorway high also, they won't see it. Sometimes I have made an opening in the fence that I thought sufficient to drive them through. This ended in disappointment; for, instead of going through, they held their heads so high they could not see the opening at all. When you make the duck-house, make the door very high. When the ducks are little they can get into it without any trouble. But when you move them into a more commodious coop, according to their growth, you want a high door or they will get their heads up so they won't

see it at all. In this climate no sort of house is needed for protection, more than one made largely of wire cloth with a large open door and wire-cloth sides. In order to manage ducklings as well as chickens, you ought to get well acquainted with them (as I have emphasized before), and *keep* acquainted. In fact, I know of few things more interesting than studying the peculiar habits and instincts of these wonderful creatures.

Now, then, in conclusion, if you want to have fun and profit too from ducklings, you want to give them *running water*. Nothing will answer in place of it. If you want to get an egg from every duck as regularly as the sun rises and sets, give them running water, study their wants, given them plenty of green food, and learn to love them, and they will love you in return and give you *both* enjoyment and profit.

All the fence needed for ducks, and small chickens also, is inch-mesh netting two feet wide. Of course, two-inch mesh, or even three-inch, will hold mature ducks; but for ducklings and small chicks nothing larger than inch will do. As ducks subsist (and thrive) largely on roots of almost all kinds of vegetation, especially in or near water, there is a great saving of expensive grain, and meal for mashies, by having them a great part of their time in "running water."

EGGS THAT DO NOT HATCH; HOW FAR ARE OUR INCUBATORS RESPONSIBLE?

On page 147, March 1, I mentioned that our sitting hens hatched almost every duck egg given them, while the incubator gave a duck for only about half the eggs, etc. As the Cyphers folks at Buffalo, N. Y., had requested me to let them know how I came out with *duck* eggs I sent them a clipping as above, and below is their reply:

Mr. A. J. Root.—Your letter addressed to the Cyphers Incubator Company for the attention of Mr. Farrington has been handed to the writer for attention. This has been done for two reasons: One is, that the writer was formerly an Ohio man, and thought perhaps you would like to receive a letter from a Buckeye boy; and the other is, that we have had considerable experience in operating incubators and brooders; in fact, we have hatched almost every kind of egg that could be mentioned in incubators. We have even hatched alligator eggs successfully, and to do this one must know a little more than the ordinary person does about running an incubator.

If we were in trouble in our apiary we would not hesitate to write you, and know that you could give us information that would place us right; and we appreciate your position, and shall endeavor to treat you as we know you would treat us.

We have read very carefully the article in your "Poultry Department," a clipping of which you have sent us, where you state that there is a big complaint of eggs for the incubator being infertile, and that that recalls to mind the down-east "secret" of starting all eggs under hens before placing them in the incubator.

To place you right in this particular phase, we beg to say that neither the incubator nor the hen has any thing whatever to do with the fertility of the egg—that is, after the egg has been laid. The germ is on the inside of the egg, is placed there before the egg is laid and enveloped by the shell. Now, regardless of where the egg is incubated, whether it is in an incubator, under a hen, or whatever it may be, the mode of incubation has nothing whatever to do with whether it is fertile or not. An infertile egg is an egg that contains no germ; and, regardless of its condition or manner of incu-

bation, it will never develop a germ. The germ must be deposited, and be in the egg before it is laid, and the hatching-machine will have nothing whatever to do with fertilization. However, the method of hatching does have something to do with the vitality; for if an egg is not incubated properly the vitality will be impaired, the germ will die, and nothing will come from its being incubated.

It is just exactly the same as a cell in a bee-comb. If the queen does not deposit the germ, it is infertile and will not produce a bee. We are sure you can see the point we are trying to make, and will understand more fully the principle of incubation from this statement.

We personally never expect to see the time when an incubator will be the equal of the old hen when she attends to the hatching business. If one were to take the results from natural incubation and artificial incubation year after year, the incubator would outclass the hens, because there is a certain per cent of them that are practically worthless as sitters. There is the same difference in hens that there is in people and incubators.

Mr. Farrington gave you some good information relative to operating your machine; but one thing that he overlooked was that the thermometer should have been changed as to its location. The position of the thermometer in the incubator is correct for the hatching of hen eggs; but if you are to incubate duck or goose eggs it is necessary that you lift your thermometer just a trifle. For duck eggs the thermometer should be about $\frac{3}{4}$ of an inch higher, and for goose eggs about $\frac{1}{2}$. The germ in the egg floats to the highest point; and if you are to have the thermometer too low you will be running the machine at too high a temperature. The consequence is that a certain amount of the eggs will not hatch, due to excessive heat.

Instead of operating the machine with the ventilators wide open, as has been suggested, you should close the ventilators down to about half open, and continue this way until they begin to pip. Then increase the heat about one degree, close the ventilators tight, and leave the same in this position until the ducklings have started to hatch out, when you can open the ventilators about half way.

The eggs, in your part of the country, should be moistened; and one of the best methods is to take a clean whisk broom and sprinkle the eggs every morning after they have been aired and cooled; and if in a temperature of 60 to 70, they should be aired and cooled for from five to eight minutes twice a day. If one is at all observing he will notice that, when the old mother duck sits on the eggs and hatches them the natural way, she will leave the nest at certain intervals, take a swim on the pond, come back with her feathers real wet, and hover over the eggs. Besides, the nest is usually built where it is damp and there is lots of moisture. This also assists in supplying a great amount of humidity.

We are acquainted with a poultryman who has made a wonderful success in hatching duck and goose eggs in incubators, and about the 20th and 26th day he dips each one of the eggs in water that is heated to a temperature of 95 to 100 degrees, allows them to remain a few seconds, when they are removed and placed in the egg-tray after being wiped or dried off.

We have endeavored to make our statements clear, and trust that you will understand the directions we have given you. If we can serve you any further, do not hesitate to write us, for we are deeply interested in your particular case, and nothing would please us more than to render you such assistance as would enable you to make an absolute success in hatching your ducks.

Buffalo, N. Y., March 23.

W. C. ELLERIN.

Of course we all agree to the above; i. e., that no hen or incubator can do *any* thing with an egg that has not the fertile germ, and I am very glad to see the writer "take off his hat" to the sitting hen and give her such a high compliment. Perhaps I should not have used the word "infertile" in my heading in that March 1st journal. Since that article came out I have started the incubator again, and again got about a 50-per cent hatch. At about the same time I gave a Bantam hen eleven duck eggs. Of course

she could not well cover them all; but it was done purposely for a test. All started germs promptly but one; but on the 29th day she came off with *ten* nice ducks. I suppose the delay was because she could not keep all of the eggs all of the time warm enough. With my exactly accurate incubator I fear I had them *too* warm, especially at the start, for they were pipped, some of them, on the 24th day, and were all out, except those "dead in the shell," on the 27th. She aired her eggs a long time, especially on hot days (and I tried to imitate her); and while the eggs were pipped and the ducklings poking their heads out of the shells she took a long promenade, as unconcerned as could be. Probably *she* had never read the careful instructions about "how to run an incubator" about hatching time. Now for my question once more: Have we any incubator that will start the germ "*in the egg*" in as many eggs (or as large a percentage of the eggs) as does the sitting hen?

HOW TO MAKE THE CHICKENS "IN THE BACK YARD" NOT ONLY SAVE THE BUTTER (SEE PAGE 147, MARCH 1), BUT THE HIGH-PRICED HAM FOR SANDWICHES.

The above is a "long-winded" heading, I admit; but I couldn't well make it shorter. Well, to get down to business, read the following from one of our old-time friends:

Dear Uncle Amos:—Being a constant reader of GLEANINGS, and interested in every thing contained therein (covers and all), and knowing that you as well as myself are interested in ferreting frauds, I am enclosing herewith a letter received to-day in answer to a letter of inquiry written by myself in reply to their advertisement.

Union Center, Wis., March 12.

ELIAS FOX.

And here is the letter our good friend encloses:

Mr. Elias Fox:—Guess you misunderstood our ad. We got tired of selling our chickens in the open market at ten and twelve cents per pound, and a year ago last fall we figured out a plan that we have used ever since, and are still using, that brings us *twenty-five* cents per pound, *live weight*, for every chicken, *old or young*, that we market, and we market chickens twice a week.

We expect your more or less skeptical opinion; but if you will be shown we will prove to you that our claim is good and that we make good.

We guarantee to refund your money if you're not satisfied. To get our advertisements in the magazines, and abide by the law, we must be prepared to back up our statements, and also be able to show that you can do the same as we are doing, or return your money to you. If you buy our method, and do not think it is worth a dollar of any chicken-raiser's money, write us for your money and we will return it to you.

What we want is to have you try our method. There are so many schemes out to grab off the dollars that we have made the following arrangement with our bank for the benefit of those who are skeptical about sending their money direct to us.

You can send the price of our method, \$1.00, to The Citizens Trust Company, of this city, requesting them to hold it for you thirty days. Notify us at the same time, and we will send you the method and you can try it. If you can not get twenty-five cents per pound, live weight, for old or young chickens, or the method is not entirely satisfactory, ask The Trust Company to return your money and they will do so. We enclose a blank that you can use for convenience. This protects you absolutely. We are doing this on the theory that the majority of people will not ask for their money back if they get value received. CHAS. W. FESTER, Man.

Elkhart, Ind., March 9.

The above sounds fair and liberal, and I at once sent the dollar. By the way, when I was in Portland, Oregon, some years ago, I found the ladies of the church were making and selling little chicken pies at 25 cts. each; and, if I remember aright, I was told a fair-sized chicken made five or six of these little pies, and they sold, too, "smoking hot," like "hot cakes." I wondered if the "secret" was not something on this line. See below, which came in due time:

A. I. Root.—Here is our method: You know that ham, such as is used for sandwiches, costs from thirty to forty cents per pound. We make what we call minced chicken, to be used in the place of ham, for sandwiches. To get it started we make about four pounds. We take it to a restaurant, lunch room, or any place where they sell lunches. We tell the proprietors that we have something that is cheaper and better than ham for sandwiches. We ask him to give it a trial, with the understanding that, if it does not sell, he will be nothing out. We tell him that, if it does sell, we should like to arrange to furnish it to him.

You see a chicken sandwich is pretty good eating. During the fall of 1910 we got 38 cents per pound. Last fall we cut the price to 25 cents, and are still getting that price. We usually make it so that ten pounds of live chicken will mince about twelve pounds. After you have made it a time or two you will know about how the weights will run.

We try to take in a supply on Tuesdays and Saturdays. We suppose you will say, "That is a hot proposition." Don't turn it down, but just try it once. Go out and get the oldest, toughest chicken, and weigh it up; make some according to formula attached, and try it out. We buy chickens of the neighbors at market price right along. We work them up this way, and it goes a long way on feedbills. I assure you. You see an old rooster looks like a springer with this plan. Now, Mr. Root, we realize that there are some people who do not live in a location where they can use this to advantage; others do not want to bother with it. We do not want to take a cent from any one who can not put this to use. If for any reason you do not want it, advise us and we shall be pleased to return your money. All we ask is, if we return a man his money he should forget all about the plan.

OSOLO POULTRY YARDS.

Elkhart, Ind., March 23.

RECIPE FOR MINCED CHICKEN.

Weigh chicken alive. Dress for boiling. Boil until done, and keep covered with water; then take the chicken out and let it cool. Take the meat from the bones and grind through a food-chopper. Weigh the ground meat. Take five crackers for each pound of live weight, and roll fine; then stir into the boiling broth. After this has boiled for a few minutes, thicken with flour as for flour gravy, until it is thick. Weigh the gravy. The weight of the gravy when added to the ground chicken should equal the weight of the live chicken. If there is not enough gravy to make this weight, add boiling water. If there is too much, take out some. Mix the ground chicken and gravy together thoroughly, and season highly. Pour into pans. White-lined granite mixing-bowls are the best. A few trials with this recipe will make you an expert.

I really believe the above is the most valuable "secret" I ever invested in, and I especially admire the vendors for not having any clause about secrecy or giving the plan to your neighbors, etc. They don't say what the sandwiches sell for, but I have paid as high as 15 cts., and got very little real chicken at that. Down here in Florida, at one of the stations, the colored folks are, I am told, making quite a little money by selling a chicken sandwich for a dime, and they are really excellent, too, as I can testify, although they are not "minced chicken." Some of you may think it hardly courteous, to put it mildly, to "give away" this enterprise. To which I reply,

it is folly in this day and age of print to expect to keep out of print any thing of value; and, finally, to reward these people, since *they* are so fair, if any of our readers build up a profitable trade in the "sandwich" line, will they not be fair enough to send the Osolo Poultry Yards a dollar, as I did?

MUSTARD FOR LAYING HENS, ETC.

On page 122, Feb. 15, I spoke of mustard to start hens laying. Here is something further in regard to the matter, which I clip from the *Petaluma Weekly* of March 20, from our good friend L. E. Keyser:

At one time I believed that nothing on earth would make hens lay. Then when some rather worthless pullets were obstinate and refused to lay when I was giving them the best of feed and care I resorted to the "Strikebreaker," and in a very little time they were laying nicely. Right here it occurred to me that, as these pullets were not valuable as breeders, and would never be used as such, it stood me in hand to get all the eggs out of them I could in the shortest possible time, regardless of future results. So we kept them laying all winter, during the summer, and late into the fall, when I thought it best to dispose of them. A sufficient number did not get into good feather at one time to make a shipment, so they were allowed to live, and about the middle of January the "remedy" was applied, and they commenced laying again with the exception of a few which were killed for home use, and laid steadily until disposed of early in September. I doubt if, without the use of a stimulant, these hens would have proven a paying proposition; but as it was, I secured two seasons of good laying out of them.

I have discovered this: It makes no difference how many eggs a hen lays during the winter, she will lay just as many during the spring and summer as though she had been idle all winter, and the winter eggs are all clear gain. If the number of eggs a hen lays is limited, the sooner we get the bulk of these eggs the better. It saves feed. It adds to the expense to feed this preparation; but the additional expense is more than met by the increased production, and it is not necessary to feed the dope all the time. Get the hens started and feed right, and they will keep going. When there is a let-up in the egg yield, feed more dope. This seems to me a logical way to treat hens not good enough for breeders. If they last only one season we know that is all they are good for; and if the hens have any constitution at all they will last two laying seasons, and lay heavily all the time except after the molt.

He also adds the following from a letter he received:

I am at a loss to know whether to approve or otherwise your action in publishing in the *Journal* for Dec. 6 the mustard formula for egg-production. I immediately invested in five pounds of mustard, one pound of saltpeter, one pound of sulphur, diluted with fifteen pounds of meat meal. At that time I was feeding every imaginable tidbit to 400 yearlings, and getting four dozen eggs per day, which hardly more than paid feedbills. In ten days I was getting 12 dozen, and in January averaged 65 per cent for the flock—lame, halt, and blind. Evidently all the *Journal's* subscribers took the bait, for to-day the price of eggs has reached the hitherto unheard-of low price of 24 cts. on Feb. 24.

I have been using mustard during the past winter, and have never had our hens lay so well before. Besides the ground mustard we are now feeding green mustard. A year ago my neighbor Rood had a plant of Florida mustard about as high as my head, with great crinkled leaves, of which the hens were exceedingly fond. He let it go to seed, and my plants were grown from this seed. It is a very rank grower on our sandy soil, and the hens just fight for it. Can we not "kill two birds" by giving them the "mustard tonic" and green feed all at one time?

Editorial

THE HISTORY OF BEE DISEASES.

THE Bureau of Entomology, Washington, has issued another bulletin, No. 98, by Dr. E. F. Phillips and Dr. G. F. White, entitled "Historical Notes on the Causes of Bee Diseases." This contains a large amount of valuable data that will be interesting and helpful in further research. We presume it can be obtained for the asking. Apply to the Superintendent of Documents, Washington, D. C.

DR. MILLER RECOVERING FROM THE GRIP.

OUR old friend and Nestor of bee-keeping, editor of Stray Straws, Dr. C. C. Miller, has been having a very severe attack of the grip. Two other members of his family have had a similar attack, but we understand they are now all convalescent. Had it not been for the fact that we have had Straws ahead, Dr. Miller's familiar notes and comments would have been conspicuous by their absence in our last issue.

GROUND COBS FOR PACKING MATERIAL.

THERE has been some inquiry regarding the suitability of ground corn cobs for cushions and for double-walled hives. We have made some inquiry and find that this material can be purchased very cheaply from feed stores, farmers' exchanges, mills, etc., as it is used for mixing with feed for cattle, etc. Those who can do so would do well to try this material, for it is a well-known fact that corn cobs will absorb a great quantity of water. Ground cork is used to quite an extent, but of the two we should prefer the ground cobs.

BEE INSPECTION IN CONNECTICUT.

FROM a report of the Connecticut Agricultural Experiment Station, New Haven, we learn that European foul brood has been the principal disease found in the State. In 1910 over three-fourths of the apiaries and nearly one-half of the colonies examined were found diseased. In 1911 only about one-half of the apiaries were diseased, and less than one-third of the colonies were infected. Of the colonies treated in 1910 and

examined again in 1911, less than one per cent were found diseased.

The usual plan of shaking colonies on clean frames and foundation was carried out, and the old hives disinfected. A few of the worst colonies were destroyed; but this was shown to be unnecessary if the treatment is given in time.

The total number of colonies inspected in 1911 was 1571, and the number reported as having European foul brood, 431. The average cost of inspection per colony was 21 cts., or \$323 in all. At the end of the report of inspection of apiaries, an appropriation of \$500 is recommended.

THE UNITED STATES STATISTICS REGARDING BEES AND HONEY; ARE THEY ACCURATE?

IN an editorial referring to the United States statistics concerning the honey business, page 67, Feb. 1st, we gave it as our opinion that they were not accurate in some particulars, adding that the statistics from manufacturers, showing the amount of supplies sold, would indicate that the bee business was on the increase rather than on the decline. The following letter is only one of many, and it explains how and why some of the census figures concerning bees and honey must not be taken too seriously:

Please tell me what the worth of the United States census is to beekeepers.

I was at home when the taker came, and I asked him if he took the bees into account. He said he did not unless their product amounted to \$400 or more. I had about 40 colonies in my yard, and yet they were not taken into consideration.

There are more bees in Massachusetts in smaller apiaries than mine than there are in larger ones, and yet they are not taken by the census enumerator.

JOHN P. COBURN.

Woburn, Mass., Mar. 22.

Before another decade rolls round, the National Beekeepers' Association should have this matter brought before the census people, calling attention to the 1910 discrepancies, and asking for a more thorough canvas of the number of colonies and bees an individual owns. Another thing, bees owned in cities and towns should be included. If the census was taken in the manner spoken of in the letter above, it is

no wonder that the United States statistics do not agree with the data in the possession of the manufacturers of supplies and publishers of bee journals. We have no doubt that the Bureau of Entomology, especially if the present men are still in office, will see to it that the 1920 census is more accurate.

THE VALUE OF HONEY AS A MEDICINE BECOMING BETTER KNOWN.

THAT honey is the base or principal ingredient in many medicines, especially cough syrups and gargles, is a fact already well known. Its value is being appreciated more and more as the following letter will show:

There are two books of authority governing the preparation of medicinal drugs found for sale in drugstores. One is the "Pharmacopoeia of the United States," and the other the "National Formula." The books are prepared by a commission of the American Pharmaceutical Society with the help of government representation. They are revised every ten years, some drugs being added, while others, for one reason or another, are dropped. In the third installment of new formulae suggested for the forthcoming new edition of the "National Formula," three out of twelve proposed additions contain honey. These three are as follows: Compound Gargle of Guaiac, 20 per cent honey; Honey of Rose with Borax, 85 per cent honey; Honey and Borax, 85 per cent honey. Of course honey is mentioned in these books already, but the substantial increase is what interests the beekeepers.

As an illustration of the importance of these books, I know a man who wrote and labored for nearly a lifetime to get one of his botanical favorites admitted in which he had explicit faith, but it was never accepted on account of its doubtful medicinal property.

Galena, Kan.

J. P. BRUMFIELD.

THE NEW GOVERNMENT BULLETIN ON SWEET CLOVER.

We have before us, from the United States Department of Agriculture, Farmers' Bulletin 485, entitled "Sweet Clover," by J. M. Westgate, Agronomist in Charge of Clover Investigations, Bureau of Plant Industry, and H. N. Vinall, Assistant Agrostologist, Bureau of Plant Industry. We do not hesitate to say that this is one of the most valuable bulletins ever issued by the government. Sweet clover, formerly regarded as a weed except by beekeepers, is now being recognized by our government and State experiment stations everywhere as one of the most valuable forage plants for stock that is grown. While it may lack some of the feeding value of alfalfa and red clover it will grow on soils where nothing else will thrive; and, what is more, it prepares the way for other valuable crops, especially alfalfa, by inoculating the soil. Evidently the authors spent not a little time in gathering the material. We would advise every one of our subscribers to send for the bulletin, especially if they live in a locality where sweet clover is regarded as a noxious weed.

It describes the different species of sweet clover as well as the history and distribution of the plant; its adaptability to various soils and climates; how to grow it; the value of the hay; how to cut it; its feeding value

for stock as well as an improver of the soil. Send to the Secretary of Agriculture, Washington, D. C.

This bulletin will do more to correct the old notion that sweet clover is a noxious weed than any thing that has appeared before—especially so as it bears the stamp and seal of our dear old Uncle Sam.

Beekeepers will now have some chance of getting an amendment to the State laws that include sweet clover as one of the noxious weeds.

FRAUDULENT PACKING OF BULK COMB HONEY.

OUR attention is called to the fact that in putting up bulk comb honey in Texas, what is called "chunk honey" is being put up in a manner that is hardly in keeping with the golden rule. The following paragraph, taken from Bulletin 142, by Wilmon Newell, College Station, Texas, to which we referred a short time ago, will explain:

A deceptive method of packing bulk comb honey has recently come to our attention, and it can not be too strongly condemned, both by customers and honest bee-keepers. As explained on a preceding page, bulk comb honey, when properly packed, consists of cans filled *full of comb* honey, the latter cut into just as large pieces as will go into the can. What few openings *then* remain are filled with extracted honey.

Some bee-keepers have, however, adopted the plan of filling the honey-cans *only about one-third full of comb* and then filling up the can with extracted honey. Of course the pieces of comb float on top of the extracted honey; and when the customer takes off the cover the can *appears* to be filled with comb honey. The deception is not discovered until the customer has purchased the can and used out about a fourth of its contents. Such deception is little short of actual fraud, for bulk comb honey usually sells at from two to five cents per pound higher than extracted; and when the customer pays the higher price for bulk comb he is certainly entitled to it, not to a mixture containing 75 per cent of a lower-priced honey.

It did not occur to us that there could be the deception practiced; but it is very apparent that, if the consumers of bulk comb honey like to eat comb honey, they are entitled to have the pail full of comb, and only the spaces filled up with extracted.

WHY WE SHOULD PRODUCE MORE COMB HONEY FOR 1912.

THE firm of Hildreth & Segelken, of New York, is one of the largest buyers of comb and extracted honey in the United States if not in the world. They therefore have unusual facilities for knowing the condition of the market as it relates to the relative production of comb and extracted honey. The very fact that they confirm our statements on the subject as given on page 221, secured through entirely separate sources, and independently of them, gives additional proof that more comb honey ought to be produced this coming season. A word to the wise is sufficient. Well, here is what Hildreth & Segelken have to say:

Mr. Root:—We are just in receipt of your April 15th issue, and note your interesting article on page 221 under heading, "Why Beekeepers should Produce More Comb Honey this Year." Your advice is certainly timely, and we indorse every word you say. The markets are practically bare of

choice white comb honey, while there is an abundant supply of extracted still on hand, with prices declining right along the line. With another good crop this coming season, extracted honey, we dare say, will see lower prices, while comb honey (that is, the better grades) will certainly command good prices, and find ready sale—especially so if the producers will take care in grading and packing.

HILDRETH & SEGELKEN.

New York, April 18.

Read it over once, and then read it again. After that, paste it in your honey-house or in your hat.

Now, then, if you have decided that you are going to produce *comb* honey the coming season, do not make the awful mistake of trying to get along without separators or putting the honey in cheap or poorly cobbled-up home-made shipping-cases that are either too large or too small. If we are ever to restore the comb-honey business to where it was, the sections must be carefully and honestly graded, scraped clean of propolis, and arrive at destination in good order. You can make a quick sale and at the top notch if you will follow these directions—particularly in the matter of grading and packing.

LIVING ON HONEY AND WATER.

ONE of our subscribers, E. L. Sechrist, Clarksburg, California, sends us the following clipping from one of the California papers:

PLACER COUNTY MAN ENGAGES IN FAST ON ACCOUNT OF ILLNESS.

For thirty-eight days A. Thommen, a well-known rancher living near this city, has been fasting, and from present indications he will continue fasting for many days to come. Mr. Thommen does not seem any the worse for his experience—in fact, there are some who think he is improving in health. He states that he is increasing in weight. A few days ago he was in the city, and while at Clegg's store lifted a sack, weighing 140 pounds, and carried it to his wagon.

Mr. Thommen, during his fast, has partaken only of water and two ounces of honey a day. He undertook his fasting because of certain stomach troubles.

Auburn, Cal., Dec. 14.

This is the first time that we have ever heard of one living on honey alone, and we shall be very much interested in the outcome of the experiment. We doubt very seriously whether there is any other food than honey, which, taken in so small an amount as two ounces in twenty-four hours, would give so much strength.

A FREE BULLETIN ON SWEET CLOVER.

Do not forget to send for Bulletin 485, on sweet clover mentioned on another page. It can be obtained free by addressing the Secretary of Agriculture, Washington, D. C. We hope every one of our subscribers will ask for it at once. A. I. Root has just read it, and he is so enthusiastic over it that he will have considerable to say about it in forthcoming issues of GLEANINGS. In the mean time get a copy for yourself and for your neighbor.

We understand that the Secretary will send copies to as many addresses as may be

sent in. Send the names of your road supervisors, and your representative and senator in the State legislature, and write them, saying that you are having a copy of a sweet-clover bulletin sent to them. Request them to read it through so that they can see that sweet clover is *not* a noxious weed; that its propagation should be *encouraged* instead of being discouraged the way it now is by law, that requires the road supervisors to treat it as a weed and cut it down.

WINTER AND SPRING LOSSES TO DATE.

IN our last issue we estimated that, where losses had occurred, the mortality would be about 50 per cent. At this writing, April 25, we fear it will go even higher. Along about the last of March, warm and even hot weather came on, and the bees began breeding strong. This was followed by cold and chilly weather, bringing on severe spring dwindling. The bees, in their effort to save their brood, chilled and died, so that we are hearing of patches of brood chilled to death, and the bees gone. In some localities where the losses reached 50 per cent, the mortality will be nearer 75.

There is going to be a most extraordinary demand for bees. In the extreme North the losses will not be heavy. South of the Ohio River bees have wintered fairly well. We shall be glad to publish free a list of those who have bees for sale in order to help out those who have suffered severe winter losses. It may be that there are some beekeepers who know where they can get colonies in box hives. If you are one of them, we advise you to secure an option on them, and then write us what you will sell them for. Ordinarily, bees in box hives are not worth more than \$2.00 or \$2.50. When freight or express are added, as well as the labor of transferring, \$2.00 or \$2.50 is about all the purchaser can stand.

WINTER LOSSES NOT UNIVERSAL.

Do not understand from what we have said that losses are going to be universal, for they are not. Throughout Canada, Northern New York, Northern Michigan, Minnesota, Northern Wisconsin, and the New England States, the losses will not be heavy. The region between the Great Lakes and the Ohio River is where the principal losses have occurred. There are many beekeepers in the Southern States who doubtless will be able to do their brethren of the North the good turn of putting them on track of bees in box hives. We happen to know of two beekeepers now—Mr. F. B. Cavanagh, of Hebron, Ind., and J. L. Byer, of Mt. Joy, Ont., who are in the market for cheap bees. While Mr. Byer has not lost in wintering, he wishes to "keep more bees."

In the same way we shall be glad to publish a list of those who desire to get bees. GLEANINGS will do all it can to help its subscribers. Indications are still favorable for a good honey year, providing a drouth does not come on in May.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

TETRACHLORIDE of carbon—has any one tried it in this country? and is it better than bisulphide of carbon? [We should be glad to get reports.—ED.]

WHICH IS the right side of a hive? Say a hive faces south; is the east or the west the right side? *I think* it's the west side, but I don't know. [Ask something easier.—ED.]

BALLING. The A B C and X Y Z instructs, "Lift the ball out of the hive and blow smoke on it until the bees come off one by one." To this should be added: "Hold the smoker far enough from the ball so the smoke will be cool. Hot smoke will make the bees kill the queen." But I like better to throw the ball in water.

ACCORDING to a table given in *Schweiz. Bztg.*, p. 467, here are the numbers of colonies of bees per hundred inhabitants in the following countries: Norway, 1.0; Belgium, 1.6; Austria, 3.8; Hungary, 4.2; Germany, 4.6; Denmark, 4.8; United States, 5.4; Switzerland, 6.5. [According to the figures of the last census, the United States would probably drop back a little.—ED.]

IRISH BEE JOURNAL, p. 24, reports a bee-keeper in the Isle of Man who took from one hive in one season 334 lbs., which, at 6d. per lb., would bring nearly \$42.00, and says, "Think of that, O GLEANINGS! as an average for one colony!" That was, almost surely, extracted honey. "In this locality" a single colony in one season yielded 300 lbs. of *comb* honey, which, at 15 cts. a lb., makes \$45.00. Think of that, O I. B. J.! as an average for one colony!

DR. C. D. CHENEY has sent me a modification of the Root hive-tool that has a good look. The right-hand corner of the chisel end is rounding, and the other corner is left square, as usual. That gives all the advantage of the full rounded end to be forced under a super, and also of the sharp angle. At a distance of 1½ inches from the chisel end there is a slight curve, raising the hand a little above the point of entrance. This gives one more power, I should think, than to push in a perfectly horizontal direction.

G. M. DOOLITTLE, you seem to favor cutting out the best of the old combs to be used over again in brood-combs, p. 192. What an old foggy you are! Don't you know that bees reared in that old comb will be dwarfed in size, and that part of the combs in a hive should be renewed each year to avoid that dwarfing? The trouble is that the bees are just as old foggy as you are. Give them an equal choice between new and old comb, and they'll take the old every time. Come to think of it, in 50 years I've never renewed a comb on account of age, and I have some fair-sized bees yet.

PARCELS POST is so nearly in sight that it is about time to be talking about the best packages for carrying comb, bulk-comb, and extracted honey by mail. They should be of different sizes up to 11 pounds each, and of such material and construction as not to leak and get honey ruled out of the mails, and at the same time as inexpensive as possible. [Do not be too sure. It is one of the tricks of the politicians to make us think that they are going to pass the legislation we want; and then when we are off our guard they stick in an amendment, or several of them, that utterly nullify the original measure. Better keep on sending postal cards to your senators and representatives, urging them to support parcels post.—ED.]

I HAVE HELD that the most vigorous bees best resist European foul brood, whether Italians or blacks. Now comes *Canadian Bee Journal*, 55, claiming that immunity is a thing separate and apart from vigor. Asiatics have developed ability to resist disease to which stronger whites would succumb—and more of that sort. Sad as it may be to crawlfish at the behest of that Kanuck, I can't muster any satisfactory reply. But I wonder if I can't, at least for a while, hold on to this position: In case of a light attack of European foul brood, the bees sometimes, if not often, clean out the disease of their own accord, and in such case it's the most vigorous colonies that do the best work. Now let's see what that Kanuck will do to me.

THIS MORNING, March 28, at 8 A. M. the sun shone brightly, temperature outdoors 40 degrees; in cellar, a shade above 50. The bees have been in cellar 136 days (4½ months). Doors had been open all night; door opening from furnace-room into beeroom. It was light enough at the pile of hives nearest the door, with entrances directly facing the door, so that at those entrances I could read with little difficulty print like this page (I used a page of Straws to try it). Although it had been open like this all morning, the bees were very quiet, not a bee flying out. The point I want to emphasize is that, with doors wide open, the air was about the same as outdoors, only warmer, and with hive entrances 2x12 the bees didn't need to stir to ventilate hives. Whatever else you do or don't do in cellar-keeping bees, do all you can to give them *pure air in abundance*. [You are just right, doctor. If a cellar is reasonably dry, with plenty of good pure air, bees will stand extremes of temperature very much better than when air is poor and damp. You can not emphasize too strongly the importance of pure air.—ED.]

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Colo.

THAT SPRING MEETING.

This will be held in Montrose, May 10 and 11. This promises to be a more largely attended meeting than the regular annual meeting in the winter. Montrose is going to entertain the Association in good shape, and every beekeeper who can possibly attend should do so. Homeseekers' rates will be on sale from Denver, Colorado Springs, and Pueblo so that these rates may be available to a good many beemen on the eastern slope. The homeseekers' rate is one fare for the round trip, good for thirty days.

Zero weather in March, with a two-foot snowfall, and the bees buried beneath it (for which I am glad) was pretty severe for Colorado; but we shall be the gainers when the honey harvest comes. Water for irrigation is assured already, as the snowfall passed the normal for this time of year, and more has fallen on the ranges than for several years. There will be more arguments for double-walled hives in every beeyard, when this cold wave has passed, in the shape of dead bees and colonies. When folks get into a habit it takes a good deal to make them see their mistake. Perhaps we shall have to have several demonstrations of the value of double-walled hives or winter cases before we change our ways.

LIME FOR THE CLOVERS

At the farmers' congress over a year ago Joe Wing referred to the use of lime for our alfalfa, and said we would soon need to use it, if it was not necessary already. I think he is probably right. Various reasons have been given for the shorter growth and less luxuriant bloom; but the lack of lime in the soil has not been given serious consideration. The winter pasturage by stock, the freezing of the alfalfa that does not stool below the ground, and the constant hauling of the crops to market and putting nothing back on the land in the way of fertilizer have all been advanced. They are all factors, no doubt; but perhaps it would be well to look into the lime problem a little. The more thrifty the growth, the more nectar for the bees. It will not do any harm for beekeepers to help the lime investigations along in every way possible.

FREE SUGAR.

It looks like it; and, regardless of our personal interests, it will be a good thing for the country as a whole. The beet-sugar interests are opposed to it, and the farmers who raise sugar beets will be drawn into the fray. We in America will have to come sooner or later to a realization of the importance of supporting public benefits in the face of private loss. I would vote for free

sugar, even though it might have a tendency to lower the price of honey. The beet-sugar industry is a very important one in Colorado, and I notice that our three Congressmen from Colorado are against free sugar. But there is no reason for alarm to the industry as I see it, and any way there is not a farmer who can not make as much from other crops as he can from beets. In fact, many farmers have given up the raising of beets; and the greatest difficulty of the sugar company is to get contracts for the raising of beets, signed by the farmers.

Colorado has seventeen beet-sugar factories, I think, and there seems to be an effort to make public sentiment against free sugar now by putting men to work at remodeling the factories. One hundred and fifty carpenters alone are reported to be at work on the Longmont sugar-factory. Whether this work is being done now to make sentiment against free sugar, it is a fact that all the news of the beet industry is finding its way very quickly into the newspapers. Much is made of the immense acreage signed up in the different districts. I believe the majority of the citizens are in favor of free sugar, and I am satisfied they are throughout the whole country. Let us have it.

A BEEKEEPERS' BUNGALOW.

I have been figuring a little recently on the trend beekeeping is taking, and I am convinced that, for the West, an automobile is the cheapest method for the man with 400 colonies or over. Now, what is the use of building an expensive shop to store all one's supplies in when one building can house the family and supplies, and auto too? A full basement under a five or six room bungalow, with the first floor three feet above the ground to give light in the basement, will house the auto and supplies for 500 colonies, and leave room for shopwork and furnace-room and vegetable-cellar. An inclined drive into the basement at the rear of the house would be provided; and with the first floor three feet above the ground the basement floor would not need to be more than four or five feet below the surface of the ground. The furnace would heat the basement to a comfortable heat for working in winter, and the auto could be loaded and unloaded right in this basement shop. This would obviate the building of a shop, barn, or garage for supplies, horses, or auto outside. The beekeeper would always be close to his shopwork, and the water supply and heat for the house would be available for the basement shop. Most of the beekeepers in the West live in town, and run out apiaries; and a home built on this plan would meet the requirements of many a beekeeper. Some of these days I will build a bungalow on this plan myself.

NOTES FROM CANADA

J. L. BYER, Mt. Joy, Ont.

See here, Arthur C. Miller, you ought to be ashamed of yourself for trying to poke fun at two innocents as you have done, Mar. 1, page 131. It so happened that the two boys referred to never knew that they were preparing an article at the same time, so you see there was no deep-laid scheme between us, and we were running a big chance of tripping one another. However, when all is said and done, you may rest assured that none of us are going to try to prevent your using a hive that needs a paper-hanger to get it in shape for winter. On the other hand, if spared till another fall this scribbler will pack the bees just a little bit *better* than ever before, for fear next winter *may* be colder than the last one.

QUEEN REARING WITHOUT GRAFTING.

The plan of getting queen cells by laying a brood comb flat on top of the combs of a colony, as described in March 15th GLEANINGS, also in March *Canadian Bee Journal*, seems to be creating a lot of interest. It certainly looks well; and in June I hope to try it on a small scale. When friend Greiner wrote it up last year it appeared to me to be something really original, although in some ways it had a resemblance to the Alley plan. It seems funny that more notice was not taken of the plan which Mr. Greiner so fully described at the time; and this only shows how prone we are to overlook a good thing until a number call our attention to it. While the plan will especially appeal to the busy home producer, I doubt if it will ever be popular with the commercial queen-rearer, as he would not care to mutilate so many combs as would be necessary when thousands of queens were being raised.

INBREEDING TO A HARMFUL EXTENT NOT POSSIBLE.

Much has been said during the past few years about "in-breeding" of bees. Of late I have been thinking the term a misnomer in so far as it relates to bees. Recently it has been my privilege to attend the short courses at Guelph Agricultural College; and after seeing how closely line bred are all our various kinds of stocks, including poultry, I have come to the conclusion that it is virtually impossible to inbreed bees to a harmful extent. Why? Simply because of parthenogenesis defeating our plans, and because of the fact, too, that, so far, we have no successful plan of controlling the male parentage. Judging from the amount of trouble that breeders of different kinds of stock have in getting true distinct types, even when they can control both sides of the parentage, I confess to being a bit skeptical as to the probability of beekeepers doing much along that line until some method is found of controlling the mating of our queens.

Regarding these short courses, it is indeed a healthy sign to see hundreds availing themselves of the benefits to be derived from these institutions. While I had little time to attend the beekeeping course, yet my few visits convinced me that there were many earnest students in attendance. The program was intensely practical, and the facilities for demonstrating very fair, considering that beekeeping has just recently been recognized. If I am correct, I believe that about 50 attended the course. I shall have more to say about this in a future issue.

WHAT ARE HYBRIDS?

Dr. Miller is quite a stickler as to the use of correct language; and yet, in common with the rest of us, he unblushingly makes use of the word "hybrid" when speaking of cross-bred bees, page 152, March 15th. Now, we all know that the term "hybrid" refers to the offspring of the crossing of two different species; as, for example, the mule in the animal kingdom, or emmer, or speltz, in the varieties of grain. As nearly as I can find out, beekeepers are the chief sinners who use this misnomer when speaking of cross-bred stock. Just why this is the case is hard to explain, unless the excuse of brevity will have to explain the matter. No, I have no fault to find, but it only shows how we can change the real meaning of a word by constantly misusing it; and after all no harm is done so long as no confusion results from the change. Possibly "shook swarming" will soon be recognized as being perfectly in order so far as the doctor is concerned.

DEEPER FRAMES THAN LANGSTROTH PREFERRED.

Regarding the discussion on depth of frames for wintering, provoked by that article of Mr. Simmins in a recent issue of the *C. B. J.*, it appears that both sides of the controversy are going to extremes, as is very apt to be the case in all discussions along this line. With the hive advocated by Mr. Simmins, certainly his claims appear ridiculous when it is considered how little difference in size there is between the hive he is censuring and the one he is upholding. On the other hand, I am firmly convinced that a frame one-third or more deeper than the L. size is away ahead of the latter for wintering outdoors in our climate. I do not say that bees can not be wintered on these shallower frames, for such a claim would be absurd; but it takes far more attention to be sure of results with this frame than it does with the deeper frame. This assertion will, I believe, be accepted by nearly all who have tried the different depths side by side. Personally I much prefer the deeper frame, but at the same time I generally advise beginners to start out with the standard frame.

Conversations with Doolittle

At Borodino, New York

PROFITABLE AND UNPROFITABLE WORK.

"Mr. Doolittle, I have been thinking that it is very easy to spend more time and work with bees than strict economy requires. What do you think about it?"

"Undoubtedly there is quite a little work done in many apiaries that is not strictly necessary, along the line of fussing with bees. At its present high price, labor is the most expensive factor in honey production, and all possible short cuts should be taken advantage of. Sometimes it is well to ask ourselves the question, 'Will this work pay?' or, 'Could not the time be used to better advantage in doing something else?'"

"What are the really necessary things to do at first?"

"The first work in the spring, where bees are wintered in the cellar, is to remove them to their summer stands; and in doing this, if the bottom-boards are turned, or a clean one given to No. 1, and No. 1's old board cleaned for No. 2, then cleaning the one taken from this, and so on, a saving will be made above a general cleaning later on, and the bees are put in better condition at the outset. Then, as soon as a day will permit, go over all colonies, seeing that they have sufficient stores to last till the nectar-producing flowers bloom, and also that each colony has a good queen."

"Is that all you do before the flowers bloom?"

"That is all that is really necessary, except where any are found short of stores, queenless, or with very poor queens. The wants of these must be supplied immediately, or as soon thereafter as is possible. After this, unless you have your hives and surplus arrangements all in readiness before, this work should be done while waiting for the honey-flow."

"But the beekeepers about me wait till their colonies become strong, or till they know just how many supers are necessary, on the ground that it is poor economy to purchase a lot of stuff and run the risk of losing many colonies or having them weakened by spring dwindling."

"That is the poorest kind of economy; for hundreds if not thousands are caught by a good honey-flow without being prepared, and the loss of this good flow, or any part of it, would more than overbalance the interest on such an investment. There is nothing like being in readiness at all times and in all seasons in the bee business. As soon as the first nectar is coming in from the fields all colonies must be looked after again, the wings of all queens clipped, the stores and brood looked after, and a memorandum of each colony made, so that the apiarist can govern his work on each during the summer accordingly. This memorandum of each will tell where the first supers are to go on, where the first work is needed in regard to the prevention of swarming, or where the

first swarms may be expected to issue, if natural swarming is allowed. It will also tell where poor queens are to be replaced with good ones, which colonies are to be replaced with good ones, which colonies are to be bred from, both as to queens and drones, and where drones are to be restricted by doing away with all drone comb as far as possible, etc."

"But do you keep this memorandum for the whole season?"

"No; but we hardly make out a full one thereafter. As hinted at, the supers are put on at just the right time, considering the strength of the colonies and the blossoming of the flowers which give the surplus honey. More supers are added at just the right time; finished supers are removed promptly, the honey graded and packed according to the demands of our market, so as to have it ready for the early price, thus taking advantage of these things in a way to bring us the most for our product. As fall draws on, the bees must be put in good condition for winter, not waiting till the last moment as so many do."

"Your question, then, could be answered very briefly by saying, 'Do things at just the right time and in the right place, leaving no stone unturned whose turning will result in profit.' The old way was, merely to hive swarms, put on and take off supers—nothing more—as the bees work for nothing and board themselves. The other extreme is, to look each colony over every week, equalize stores, raise queens, take each section off as soon as sealed, feed for winter, etc. The practical course does not reach half way between these two extremes. The farmer loses much honey by not doing a few things at the right season. The practical, economical, professional apiarist does just those things, but no more, and at just the time for the best results."

Extracting Uncapped Honey Not Practiced Generally in New Zealand

Having noticed some time ago a letter from Mr. Isaac Hopkins, advocating the extracting of honey before it has ripened in the hive, I wish to state that Mr. Hopkins stands alone in that matter so far as the beekeepers of New Zealand are concerned. We had an exhibition here some years ago. Mr. Hopkins, then acting for the government, was running an apiary in connection with the exhibition. At that time he was practicing his plan of premature extracting; but the sample of the honey in Agricultural Hall soured and started to ferment; yet in spite of such adverse experience he still advocates the plan. He quotes Mr. Alexander as supporting him; but it must be remembered that the conditions upon which Mr. Alexander based his theory were altogether different from what we have here, as buckwheat is not grown here to any extent, if at all. I am glad to see that all the criticism of Mr. Hopkins' ideas have been adverse; for although, under some circumstances, it may work without disaster, yet in most cases it can never be a success.

MAKING INCREASE

The Importance of Becoming Acquainted with the Advice in the Best Books on the Subject

BY DR. C. C. MILLER

[The following is a reply to a question asked by J. G. Nance, Keyil, Ky., on the subject of making increase. Mr. Nance sent the same inquiry to Mr. Doolittle, whose reply appeared in the last issue, p. 227.—ED.]

Your question is a very broad one. Unfortunately—fortunately in some respects—there are more ways than one of making increase. Indeed, taking all the variations that may be made, there are more ways than a dozen. What is the best way for one may not be the best way for another. What is best in one locality may not be best for the same man in another locality. What is best for one season may not always be best for another season. Indeed, what is best for a certain man in a certain locality and in a certain season may not be at all best for the same man in the same locality and in the same kind of season, if in the first case he is entirely without experience; and in the second case he has made great advancement. So I think you will see that, to be able to advise you satisfactorily, I ought to be well informed as to you and your surroundings.

I feel safe, however, in giving one general bit of advice to any one who wants to know the best way to make increase. It is, to inform oneself thoroughly on general principles. Make yourself thoroughly familiar with the contents of one or more of the excellent books of instruction about bees, such as Root's A B C and X Y Z. Even things that on the surface seem to have no connection with the subject of increase may have a vital bearing upon it. Then give special attention to the matter of increase itself. Read up all you can in all the books and papers at your command that tells any thing about increase. I do not hesitate to recommend to you the book "Fifty Years among the Bees" as being as full upon the subject of increase as any book you can find, beginning at page 265. Having thus informed yourself you will likely be able to tell better than any one else what will best suit your case.

After generalizing in this way I will not leave the subject without some attempt at particularizing; and if I can not tell you what is the very best way for you I can at least say something about a way to do.

It is just possible that natural swarming may best suit your purpose. But if the bees are left entirely to their own devices, natural swarming is likely to be more or less unsatisfactory. They may swarm too little. They may swarm too much. The poorest colonies may swarm two or three times each, and the best colonies may re-

main without swarming. Well, then, don't leave them entirely to their own devices, but take a hand in the matter yourself. If there is any choice as to stock, select about five colonies that you think are the best of the nineteen. Suppose A is one of those that are thus selected, and that B, C, and D are three of those not selected. Take from one or all of B, C, and D some of their fullest and ripest frames of brood, and exchange with A for its poorest, thus strengthening and encouraging it to swarm. When A swarms, hive the swarm and set it on the stand of A, putting A in place of B, and setting B in a new place. The field bees of B, when they return from foraging, instead of returning to B will go straight to their old location and join A. That, of course, will strengthen A. In about eight days the first young queen in A will emerge from its cell, and a swarm will issue. Hive this swarm and set it in place of A, and set A in place of C, setting C in a new place. Within two or three days A will swarm again. Set the swarm in place of A, set A in place of D, and set D in a new place.

You have now accomplished two things: You have made sure of a swarm in place of each of the colonies B, C, and D, which, without your interference, might not have swarmed at all and you have made sure that each shall have a queen of good stock.

Of course while all this has been going on you have performed in the same way with the other four of your selected colonies; and when all the colonies have been replaced by a swarm you will have 38 colonies in all. That is not as many as you want. Well, when you set A in place of D, probably A will swarm again in a day or two. When it does, you can set the swarm in place of A, and set A in a new place. If you do the same way with all of your selected colonies, that will add five more to your number, making 43 in all.

If you want to go beyond this, instead of putting A in a new place when it swarmed the last time on the stand vacated by B, set A in the place of C, putting C in a new place. Then when A swarms again you can set A in a new place unless you want to go still further.

The show may not come off exactly according to program, for there is a possibility that, toward the last, the swarm will not issue. There is very little doubt, however, about reaching the first 38. On the other hand, there is a possibility that, when A or one of its compeers is set on a new stand for the last, with the understanding that it will swarm no more, it may take it into its head to send out another swarm, although it will be a weakling. If this weakling is not desired, it may be put in a dark cellar for 24 hours, and then returned to the hive it came from.

Marengo, Ill.

IS SWARMING A CAUSE OR RESULT?

BY J. E. HAND

Swarming is the fulfillment of a natural impulse of bees, and is governed by certain fixed laws. Since swarming and queen-rearing are inseparably connected, the popular theory is that swarming-cells are constructed in obedience to a desire of the bees to swarm. Right here the question arises whether bees prepare for swarming by the construction of swarming-cells or whether all queen cells are constructed in obedience to certain fixed laws over which they have no control. In the latter event, swarming would be the effect instead of the cause of queen-cell construction. While many will not accept this theory, I think all will agree that the presence of a plurality of queen cells will cause after swarms to issue so long as a queen cell and a handful of bees remain, provided external conditions are favorable.

The popular theory prevails that there are two conditions under which "queen-right" bees rear queens, viz., swarming and supersedure. Who can distinguish between swarming and supersedure cells during a honey flow? To my mind, a more reasonable theory is that all queen cells are constructed in obedience to an inborn instinct to supersede either a failing or a departed queen. For instance, a combination of forces compels the construction of supersedure cells, and the presence of queen cells in a brood-chamber already having a vigorous queen places the colony in an abnormal condition; and the law of self-preservation, impelled by the power of instinct, compels the bees to seek the lines of least resistance by migrating to a new home, and hence the issuing of the swarm.

Doubtless some will say that bees will not construct supersedure cells while a vigorous queen is present. It is generally conceded, however, that, if a vigorous queen is caged within the hive in such a manner as to restrict her in the performance of her natural function (laying eggs), supersedure cells will usually be constructed. Hence it is evident that any thing that will have a tendency to restrict the queen in the performance of her natural function will operate as though she were actually failing. While restricted function is not the direct cause of swarming, the psychological condition thus produced will develop the queen-rearing impulse to the highest pitch, and supersedure cells will be constructed regardless of external conditions. Thus while the swarming instinct is always present, there will be no swarming unless the forces are present that nature employs to develop the queen-rearing impulse. While a slight restriction of the function of the queen may not be noticeable to the apiarist, it is, nevertheless, manifest to the unerring instinct of the bees to supersede a failing queen.

If the event transpires outside of the period of nectar secretion, and especially if

the diminution of egg production is due to a defect in the queen, supersedure will be the result. On the other hand, if the fertility of the queen is not exhausted, and if the decrease in egg-laying is due to restricted function of the queen, caused by an overcrowded condition of the brood-chamber, and if external conditions are favorable, swarming will be the result.

If the above deductions are correct, it is evident that any thing that will break up the combination of forces that nature employs to develop the queen-rearing impulse will prevent swarming; hence the importance of always having a young and vigorous queen in every hive. While a vigorous queen in a large brood-chamber will have a tendency to prevent the development of the queen-rearing impulse, perhaps some method of separating the bees and queen from their brood at the beginning of the honey flow is the surest and most economical method of swarm control. Such a method would provide ample room for the queen to exercise her natural function, and therefore the forces that develop the queen-rearing impulse are not present, and swarming is controlled. The segregation of many colonies near together is contrary to nature; therefore the fact that, under these conditions, bees will often swarm in open violation of all rules and regulations should not be taken as evidence of an error in the theory, but rather as an instance of abnormality caused by the excitement consequent upon the issuing of many swarms near each other.

Birmingham, O.

RHEUMATISM AND BEE STINGS

The Poison of the Stings Valuable for Only Certain Types of the Disease

BY J. B. TALMAGE, M. D.

I notice that from time to time various cures for rheumatism are presented to the public with somebody's recommendation that the one he describes is a sure cure. In GLEANINGS the favorite remedy discussed pro and con is bee stings. It is not my purpose to make GLEANINGS a medical journal, but it seems a matter of interest to consider briefly why so many cures are proposed, and said to be good or worthless according to each one's experience.

It should be known that the term "rheumatism" as commonly used covers a class of diseases such as inflammatory rheumatism (true rheumatism), muscular rheumatism (myositis or myalgia), articular rheumatism, rheumatoid arthritis, sciatica, etc. The character of these diseased conditions differs widely, and necessarily the same must be true of their treatment. Further, two cases that would be diagnosed the same might require different remedies for their cure because of the difference in the chemical and physiological condition of each individual. Physicians well understand that

the name of a disease can not be successfully treated, but that the patient must be treated in the diseased state that he presents. Hence his case must be studied and treated individually.

To illustrate this point and show the value of the poison from the honeybee (formic acid) in treating suitable cases of rheumatism I will relate two cases from my practice. A few years ago a man came to me, stating that he had rheumatism, and that he understood that I could cure such cases by giving the sting of the bee. He was assured that rheumatism could be treated in that way if the symptoms indicated that remedy. After getting his symptoms, and finding that drug well suited to his case, he was given the remedy, prepared in very small doses. After a time his neighbors told me that he was very much improved, and later he came in and said that the rheumatic pain had all left him.

A little later another man who was a great sufferer from a rheumatic condition, having talked with the one who was cured, came to me and very much desired to be cured in the same way. Upon taking his case carefully, I assured him that his case was different from the first, and that it was doubtful if he would receive benefit from the drug. As he was anxious to give the stings a trial he was given the same dosage the first man received. After taking the medicine without results he came the second time, and the prescription was repeated and faithfully taken, with no results whatever.

From the above it should be clear to every one why those who have been stung by bees have been cured of their rheumatism, and equally plain that the other rheumatics who submitted to this painful ordeal declare that stings will not cure rheumatism. From this we may see why one may recommend grape fruit, another hard cider, and a third something else. There is no panacea for rheumatism or any other disease.

If those who wish to try stings would consult their nearest homeopathic physician they could learn whether that was their remedy before undergoing this heroic and painful treatment at random, not knowing whether it would hit or miss. Homeopathy has used this remedy for very many years. Its symptomatology is based upon definite proofs so that the treatment need not be applied in an uncertain way.

Ladoga, Ind.

THE GREEN FLOWERS OF NORTH AMERICA

BY JOHN H. LOVELL

[This is the second article in the series by Mr. Lovell, on the colors of North American flowers, the first appearing on page 53, Jan. 15.—ED.]

The primitive color of flowers was undoubtedly green. Many years ago the German poet Goethe proposed the theory that the whole flower was only a metamorphosed bud, or part of a branch of leaves, the mod-

ified leaves serving as pistils, stamens, petals, and sepals. Despite many attacks, this view is still accepted as true, at least historically. In most flowers the calyx has remained green; and in some species, as the hepatica, its derivation from leaves is evident from inspection. It is not uncommon for both sepals and petals to revert to green leaves, and I have before me a flower of the fuchsia with three white petals, while the fourth is a green leaf. This may even happen to the entire flower. In the Black Hills a fossil "flower" of a cycad-like plant has been found by Professor Wieland, of Yale, which is protected by an indefinite number of bract-like leaves instead of by a calyx or corolla.

The green hue of both green leaves and flowers is produced by the pigment called chlorophyll, or leaf-green. If you put a few grass leaves in alcohol the chlorophyll will dissolve out, forming a yellowish-green solution, and the leaves will be left perfectly white. Place this solution in bright sunlight, and its color will soon be destroyed. In living leaves and green flowers under the action of bright light the green pigment is constantly being destroyed and renewed, so that no two leaves are identical in hue, and no leaf long remains of the same shade. We are surprised to note that Freidank, a German poet, who lived four hundred years ago, observed this fact.

Many hundred flowers
Alike, none ever grew;
Mark it well, no leaf of green
Is just another's hue.

Leaf-green, or chlorophyll, is not only the most common but it is also the most useful of all pigments, for all life depends upon its existence. Leaves containing this pigment are able to make use of the energy of the sunbeam, and to manufacture out of water, and the carbonic dioxide in the air, starch, one of the principal plant foods. That is, out of the inorganic elements they build up an organic substance. As all animals are dependent either directly or indirectly upon vegetation for support, the destruction of chlorophyll would mean the disappearance of life from the earth. All living beings are dependent upon the radiant energy of the sun and upon chlorophyll. "In this sense," says Tyndall, "we are all 'souls of fire and children of the sun.'"

Of the 1244 green or greenish flowers found in the northeastern States, by far the larger part, or 1021, are pollinated by the wind. They contain no nectar, and are visited by bees only for pollen, and not as extensively as would be expected for even this purpose. They are all of small size, and by some botanists are believed to be derived from ancestors which were larger and were pollinated by the insects. Failing to attract a sufficient number of visitors for this purpose they have retrograded, and become adapted to pollination by wind. It is desirable that this group be recognized by beekeepers, since otherwise they might expect their bees to bring in nectar when it did not exist.

Only 223 green flowers are pollinated by

insects or are self-pollinated. Most of them are small or even minute; many have no petals, as 15 species of the buckwheat family, 8 species of the pink family, and also several in the rose family. While they very generally have the power of self-fertilization, as in the small flowers of the pinweed (*Lechea*), in some instances the sexes are borne on different plants.

They are chiefly attracted to flies and the smaller bees; but the yellowish-green pendulous flowers of the garden asparagus are very frequently visited by bees for nectar. The large greenish panicles of the sumac are also very attractive to bees. Mr. Allen Latham has described in GLEANINGS how in Connecticut, if there is fair hot weather in July, a colony of bees will store from 20 to 100 pounds of honey from *Rhus glabra*. The honey is described as golden in color, and at first intensely bitter in taste; but with age it acquires a most agreeable flavor.

Our common species of sumac in Maine is not *Rhus glabra* but *Rhus typhina*, which is often common in dry uplands. Besides bees, which are frequent visitors, I have taken on the flowers a large company of wild bees, flies, beetles, and even butterflies. The staminate flowers are white, and much oftener visited by insects than the green pistillate panicles. Some of the smaller bees which visit the former, apparently never visit the latter.

In the grape or vine family the small valvate petals never expand, but fall away by separating at the base and coiling spirally upward. The fragrance, which resembles that of mignonette, can be perceived at a long distance. Kerner relates that, in a journey up the Danube, he found the whole valley of the Wachan so filled with the scent of the vine flowers that it seemed impossible that they could be far off; yet the nearest vines were three hundred yards from the boat. The bee has been collected on the flowers, and cross-pollination is also occasionally effected by the wind.

Various exotic species of the nightshade family and some Brazilian orchids possess large green flowers. They are strongly scented in the evening, and are attractive to moths. As would be expected from their size, structure, and past history, the majority of green flowers are of little value to beekeepers. But in his list of honey plants of Texas, Scholl mentions several other shrubs or trees, besides the sumac, with small greenish or dull-colored flowers which produce nectar abundantly.

Waldoboro, Maine.

DOES IT PAY A BEEKEEPER TO MAKE HIS OWN HIVES?

BY G. C. GREINER

Since the appearance of my pictures in the July 15th issue for 1911 I have had numerous inquiries, both verbal and by letter, in regard to the practicability of beekeepers making their own hives; and the main

point always seemed to be the financial part of it. The questions asked run something like this:

"Do you think it would pay me to make my own hives?"

Without entering into any detailed discussion, my answer would be, "Yes, under certain conditions; but as a rule, emphatically no."

Years ago, when hive-making occupied more of my time than it has for the last ten or fifteen years, I expressed my opinion on this subject in one or the other of our bee magazines. To take up that subject again now, seems like dishing up an old story, and undoubtedly it is to some older beekeepers; but during the last decade or two a new advice-seeking generation has sprung up, and for their benefit I give my views again.

The prospective hive-maker may be anxious to know what those "certain conditions" are. I will enumerate them in the order of their importance:

1. The hive-maker must have a fair knowledge of bee nature, especially in regard to the way bees use the inside of a hive for comb-building, brood-rearing, etc.

2. He must have access to true-running, properly arranged power rip and crosscut saws, and be handy with a planer.

3. He must have a certain amount (the more the better) of natural mechanical inclination, and—

4. His necessary supply of lumber must be obtainable at a reasonable rate.

To the uninitiated, the first one of the named conditions may not seem of sufficient importance to take the first place. He may think that almost anybody can follow the instructions a properly constructed model will give. That may be true in some cases. We did the same thing when we launched out on our present occupation; but we happened to have a model to work from that allowed changes with no great inconvenience and expense, when progress and advancing ideas made them desirable. With others it may be different. It may not be long before the individual's experience may, for various reasons, make a change desirable. He may want to change from comb to extracted honey, or from one size of section to another, or change from eight to ten or ten to eight frame hives, and so on. All this would necessitate a change of appliances, which, after once started in with a quantity of a certain pattern, would be very inconvenient and expensive, or else it would cause a mixed lot of different sizes and dimensions among the outfit, which would be equally objectionable, for the most rigid uniformity in every thing is strictly necessary in any apary. It is the keynote to convenient and rapid work. A little forethought on the part of the person who contemplates taking up beekeeping for a living, a little more study of our textbooks and literature, comparing his readings with his locality, his demand, and the outfit he intends to use,

etc., before he decides on any certain make of fixture, may prevent disappointment later on, and start him on the right track.

The second clause of "certain conditions" is of next importance. The whole outfit displayed in the above-mentioned pictures is all *home* made but not *hand* made. Every piece used in the makeup is fitted by power saws and planer. I am frequently asked, "Did you make your hives by hand?" I simply smile, and say, "Yes, I nailed them by hand, and I painted them by hand, and handled the lumber by hand when fitting the material; but I had power saws and planer to help me." Although I have done mechanical work all my lifetime, I consider fitting hive material by hand a task all out of the question. There is not a mechanic in the country who, with all his skill, can fit a single hive body, end piece, or make a main-frame topbar by hand as nearly perfect as true-running machinery will make, to say nothing of making it pay in quantities.

Next in order is the mechanical skill of the operator. Even when we have the necessary machinery at our command, it requires no little ingenuity to keep it in proper running order. It seems like an easy matter to set the gauge of a saw twice alike. It is for nearly all housework, even for door and sash manufacturing, that a little variation is many times admissible; but if positive uniformity is our aim, hive-making requires more exact measuring than almost any other kind of woodwork. As an illustration of what uniformity in an apiary means, I refer the reader again to the above-mentioned photographs. From a superficial view, the whole outfit seems to be uniformly made; and, in reality, we find that this is the case in every particular. Although the material was manufactured at different times, at intervals of from one to ten or fifteen years between different portions of it, every separate part, such as hive bodies, bottom-boards, covers, stands, etc., is interchangeable with every other one of the same kind; and, more than that, every separate piece, large or small, used in the construction of those different parts, is a perfect counterpart of every other one of its kind. When we started hive-making at the beginning of our beekeeping career, in 1876, and had decided on the kind, size, dimensions, etc., of our output, we made a list containing every separate piece used, and described it by its exact length, breadth, and thickness for our guide to work from. To this list we adhered, year after year, as closely as close measuring made it possible, and to this day I use the eccentric-lever forms for nailing main and broad frames (section holders) I made at that time, 36 years ago. The result of persistently applying our little available mechanical talent to our work is the complete uniformity in our apiary. The benefit derived therefrom can not be overestimated.

The lumber question, the last of the four requirements above mentioned, has also

considerable bearing on making home manufacture a paying venture. Thirty-six years ago, when the hills of our home town, Naples, were yet covered with uncultured pine forest, average lots of lumber could be bought from almost any neighbor at from \$12.00 to \$15.00 per 1000. These lots would contain any thing from six to sixteen or eighteen inches wide, and run from more or less knotty to clear or practically clear lumber. In sorting out the different grades to best advantage we could generally work up any lumber-pile into quite respectable-looking hives.

But times have changed. Our New York hills are pretty well stripped of pine or any other timber, and we are compelled to call on our local lumber-dealers, who import their stock from the West, for our supplies. Under these circumstances the prices of all kinds of lumber have risen to such dazzling heights that the pocketbooks of us common beekeepers can hardly reach them. To-day we would have to pay for fairly clear lumber (not strictly clear), such as would be desirable for hive bodies and cover tops, anywhere from \$60.00 to \$80.00. This item alone puts an unpleasant damper on home hive manufacture.

After making a brief statement of the foregoing, the inquirer generally asks: "How, then, can I get my supplies?" Very simple. If a person feels anxious to occupy his leisure time, and wishes to make use of the mechanical inclination he may be favored with, the shortest and most convenient way to procure his outfit is to order the fitted material from any of our established bee-supply manufacturers. They keep standard goods constantly on hand, and can fill an order on short notice. In case their list of supplies does not include the desired kind or any particular make we wish, by giving an exact description they will make to order any article desired; and, what is the best part of it, their work will be far superior to any home-shop productions.

In regard to expenses I know from experience that the price of fitted material is little, if any, above the cost of the raw lumber it would require to make the goods. For various reasons a part of my outfit was procured in this way some years ago. To prove that I do not overrate the exact workmanship of our bee-supply establishments, I will add, incidentally, that these ordered goods were made so near to given measurement that no variation could be detected from those of my own make.

Upper Ventilation Makes the Honey Too Thick

As I work away from home I ventilated my hives by raising them $\frac{3}{4}$ of an inch from the bottom-board. I also put two one-inch auger-holes in the top of the brood-chamber, and kept on full-depth extracting supers. I fixed ten colonies in this way without increase. One colony, whose hive was not ventilated, cast two swarms. I do not like ventilating here, as the moisture dries out of the honey until it is too thick to extract; but I believe that the plan is all right except in arid regions.

Allowing the bees of a swarm to run directly from a small cherry tree into a hive.

A SWARM THAT TOOK ENTIRE POSSESSION OF A CHERRY TREE

BY R. C. SCOTT

The swarm shown in the engraving issued from a hive about the middle of August, and settled direct on this cherry tree. I placed a new nine-frame Massie hive by the tree, and the swarm entered it, although the hive had only the bare frames. After that time the bees filled the brood chamber clear full, and stored 15 lbs. in the super.

Segundo, Col.

CARNIOLANS NOT SWARMERS

BY LOUIS SCHOLL

After having quite a number of colonies of Carniolan bees in our apiaries for several years, both pure and crossed with blacks or Italians, we may say that we have never had any trouble with these bees swarming more than any other that we have observed. Our experience has included every variety of bees that have been popular at one time or another, such as blacks, Italians (goldens and three-banded), Cyprians, Holy Lands, Carniolans, Caucasians, and Banats, and various crosses of several of these races. We have, however, attributed our success in controlling swarming of even the much-condemned Carniolans to the large hives

we use. They are ten-frame hives which we adopted years ago after trying them side by side with the eight-frame hives, in every possible way, trying to make the best use out of them, since we had them on our hands. In addition to the regular ten-frame hives we have the ten-frame divisible-brood-chamber hives that are still better for this purpose of swarm control, since many manipulations can be made with this kind of hive that are not possible with the regular hives.

But recently we received a letter from a Carniolan queen-breeder, Wm. Kernan, in which he says in part, "You will find that Carniolans will do best in ten-frame hives. They seem to do better than in eight-frame tiered up. If you have any ten-frame hives, try them; and if you give them an abundance of *drawn comb* they will never swarm. I think Moses Quinby told us this." This shows how nearly right we were in our supposition and the use of the ten-frame hives.

This is a matter of importance to the honey-producer who wishes to make large crops of honey instead of swarms, and especially if the bees are in out-apiaries. While it may be argued that other races would be better than Carniolans, we have two apiaries of them, and rather like their good qualities. They are large bees to begin with, although those who do not like a black bee may object to the color of the Carniolans. However, the person who studies their color and particular markings more closely will find

that their beautiful ashy-gray color is no uglier than the color of other bees. Then they are docile in their temperament, and quietly remain on their combs when handled, so that it is a pleasure to work with them. Especially during a honey-flow, when these great big fellows filled with honey drop from the combs with a heavy thud, the apiarist who is at all a student of nature can not keep from admiring them.

Another good trait is that they build up early in the spring—an important item where the spring flows come early.

As is well known, they cap their combs rather whiter than some of the other races, and this makes them excellent for producing fancy comb honey. Their excessive swarming has condemned them, however, in spite of these good qualities; but it seems that, with the proper hive and methods, this objection may be removed, at least to some extent. This would make the Carniolans seemingly a more valuable race than they have heretofore been reputed to be.

HOW AN EXPERT HANDLES A SWARM

Jacob Alpaugh Caught in the Act

BY F. DUNDAS TODD

There is a Scotch saying, "A gaun fit is aye getting", though it be but a broken tae." I am a scion of the tribe of the wandering foot, sometimes getting only a broken toe, but often something I appreciate more highly. Last summer, as bee inspector, I wandered to the tune of several thousand miles by rail, steamer, motor-boat, buggy, and canoe. Luckily for me I pulled through without breaking even a toe; but instead I got quite a lot of photographs, many of which concerned bees. I had a lot of fun taking them, and I want to pass a few of them along to the readers of their journal.

One morning I started out with a definite day's work planned; and as I jogged along, the idea came into my head that I ought to go and see a beekeeper whom I had formerly visited. I really had no particular excuse

FIG. 1.—The swarm in the tree.

for calling again; but just as soon as the notion jumped into my brain I decided I would be foolish for once and follow the whim.

On arriving at the apiary I found myself greatly rewarded; for just about the time I changed my mind Mr. Jacob Alpaugh, of Ontario, had happened on the scene, so here he was running a little bee convention for the benefit of only three people, and I hastened to raise the total gathering to four. We were comparing notes on the subject of swarming, when a swarm very opportunely appeared in the air. It was the first bee convention I had attended where a practical demonstration could be given just as soon as a subject was under discussion, so I quickly suggested that, if Mr. Alpaugh showed us how the beekeepers of Ontario handle a swarm, I would equalize matters by demonstrating how a beekeeper in British Columbia could photograph it. The bargain was considered fair and equitable, so I produced my camera, and he asked for a dishpan, a smoker, and a sheet. Nobody paid any attention to me.

Why did he prefer a dishpan, and what did he want with a smoker? The dishpan, he told us, was to be preferred because it was so smooth that the bees could not cling to it, and so were easily shaken off when they were dumped on the sheet in front of their new home. This was the first time I had ever heard of a dishpan being chosen

above all other utensils; but later in the season I met another beekeeper who had adopted it; but he hastily added a word of caution, to the effect that the pan should be kept away from the direct rays of the sun until it was needed, because, when the sunlight beats directly upon the pan, it gets very warm. One such experience with a hot pan was more than enough for him; for the moment the bees struck the hot metal they rose in a cloud, full of evil temper, attacking every living thing in sight.

In the matter of the smoker, he said he believed that a swarm clustering on a branch had guards set, just as if they were in the hive, so he always gave them a little puff of smoke to upset their equanimity. The sheet was thrown in front of the hive, that the bees might have a surface for walking on that was smoother than grass.

All preparations being made, Mr. Alpaugh got busy and so did I. He kept hustling, and it was up to me to press the bulb, turn on a new exposure in the kodak, and press again. I began with the swarm hanging on the branch; the result is shown in Fig. 1. Then Mr. Alpaugh got started to his work by puffing a little smoke on the bees as exhibited in Fig. 2. In the next photograph, Fig. 3, the button was pressed as he shook the branch, so all we see is a streak of bees. Proceeding to the hive Mr. Alpaugh gave

FIG. 2.—The preliminary smoking.

FIG. 3.—Shaking the branch and dislodging the bees into the dishpan.

the pan a sudden jerk that landed most of the insects on the white sheet (cover picture for this issue).

There was now time for a little conversation between Mr. Alpaugh and the owner of the apiary, as they "hunkered" (no English equivalent for this Scotch word) on opposite sides of the hive. Suddenly the visitor's hand shot out, and "There's the queen!" fell from his lips. Luckily I was prepared, so the incident is on record in Fig. 4.

DO BEES HEAR?

A few feet to the right of the hive there stood some kind of grass which had attained a height of about four feet. All the time the swarm was finding its way home, many bees—say a hundred—could be seen flying out and in among the stems, now near the ground, now higher up, as if they were searching for something. Mr. Alpaugh asked if I could give any explanation of their conduct. I threw up my hands at once, remarking that once in a while I had seen the same thing but never could account for their behavior. Then he remarked that this wandering around what was practically a solid wall was to him the best proof that bees could hear, for these stray bees heard the echo of the hum from the hive, and were searching for their companions. He

FIG. 4.—There's the queen!

had first noticed the condition when hiving swarms close to a solid fence; then later observation showed that, when the hive stood in the open, nothing of the kind happened.

NO PROTECTION AGAINST STINGS.

Mr. Alpaugh is the first beeman I ever met who works without any protection from stings when handling the bees. We spent a couple of days together, opened many hives, often upset the bees considerably, for frequently I had to cut down through the transversely built combs by cutting through the V-shaped edges and force them in line. The bees do not like this treatment any too well, but they always left Mr. Alpaugh alone. He smoked them considerably more than I ordinarily do. In addition he puffed smoke into his beard as a protection to his face. I have been wearing whiskers for 30 years without finding any special use for them, so it rather tickled me to find one man who had found the hair on his face to be of some use, even if it were only as a smoke-holder.

In my wanderings on the northern half of Vancouver Island later in the season, I came across the most vicious bees I ever met. At one seacoast village I had inspected the bees in the forenoon, creating quite a little excitement. A tethered horse smashed a dozen pickets out of a fence; all the dogs in the community, after snapping viciously at every part of their anatomy within reach, had hiked hurriedly for shelter, so that, where about a score had formerly slumbered in the open, not one was now visible. The grocery store was filled with agitated women; the only saloon was briskly dispensing liquid antidote for bee-stings.

Luckily for me the steamer appeared on the scene, so I hastened on board while the getting was good, and so avoided the rush. My next day's wandering brought me to the same pier, so I leaned over the side of the ship and inquired in my softest voice if bees did well on the island. Instantly a huge fist was lifted in my direction, and an angry voice assured me that no living thing had been safe since yesterday at noon. The grocery store was without customers; the owner's sole occupation and recreation was to watch some occasional man putting on his best speed while he frantically fanned the atmosphere with his hat. He invited me to come ashore; assured me that a very large and influential deputation of the inhabitants was just aching to interview me—had cried all night because they believed they would never see me again. Much to his regret I had to decline the earnest invitation—the most urgent and the warmest I had ever had in my life; but I could not get him to believe that were other communities who were sighing for my presence.

Victoria, B. C.

REMOVING A SWARM FROM A PEACH TREE

BY J. B. REYNOLDS

I am sending some pictures of a swarm of bees showing where it clustered on a peach tree. I shook them into a large box and carried them to the apiary and poured them out in front of an empty two-story hive in the corner, which was the location formerly occupied by the parent colony.

Convoy, Ohio.

EXTRA RAPID INCREASE

How One Colony was Increased to Thirty in One Season

BY G. H. ADAMS

On the 20th of May, 1909, a friend of mine, Harry Fort, of Greenwich, N. Y., got a strong colony of Italian bees of me. He wanted more; but I advised him to wait and see how many colonies we could make in one season from this one. To my astonishment we were able to increase that one, with a few extra drones (as the queen did not lay drone eggs that season), to 30 strong colonies, the bees building all their own comb and rearing nearly all their own queens. We did it by dividing. We found it necessary to do some feeding, however, toward the last, as the season was poor.

In order to give a description of the method followed in making the increase it will be necessary to tell what kind of frames and hives I use. My brood frame is $11\frac{1}{2}$ inches deep and $11\frac{1}{2}$ long—nearly the same size as the Gallup. I consider it the best frame for all purposes ever used. I have tried the Langstroth and several other kinds, but do not like them. These frames being deeper, bees winter better on them. The extractors cost less for this kind of frame, and the combs of honey hang in them the same as they do in the hive, making it easier to extract without much breakage of combs. With the Langstroth frame very many break out when the combs are heavy, as they have to stand on end—at

J. B. Reynolds hiving a swarm clustered on a peach tree.

One colony increased to an apiary of thirty during 1910, the bees building all the combs from half-inch starters.

least that has been my experience. Bees build up faster in the spring in these frames, as the hives are more compact.

I use two sizes of hives, both of them of my own design — one an eight-frame hive which I use when running for increase, for shipping, and for wintering. The other, a sixteen-frame, is nearly 25 inches long, outside measure, and is used only for the production of comb or extracted honey. This I call my non-swarmer hive, and I never had a colony swarm when the hive was tiered up three stories high, and only one swarm in 25 years, that I know of, when it was tiered two stories high. I make all my hives with a half-inch space above and below the frames excepting the brood chambers, which have a little more than an inch space below the bottom-bars.

Mr. Fort used nothing but half-inch starters in the brood frames, the bees building all their own combs except the starters. This queen was one of the best layers I ever saw. On May 29 I went to his place and examined the colony, and found seven full combs of brood and one comb full of honey. I took two combs of brood nearest ready to hatch, and the comb of honey, with plenty of bees on all three, and the queen, and put them in an empty hive quite a distance away. I shook the bees from two more combs from the old hive into the new one, knowing that many of the bees in the hive just made would return to the old location. I then placed five new frames with starters in the new hive and three new frames in the old queenless hive.

One week from this time I made two more small colonies from the queenless part, giving each part two nice queen cells. Of course the old hive with the one comb of brood was fully as strong as any, as most of the field workers were there. Note that the queen cells were all started where the field bees were. There were none in the new hive with the queen.

Mr. Fort painted some of his hives green, some white, and some red. Every young queen mated safely this time, and the four colonies were soon strong.

On June 26 the hive where the old queen was located was packed full again. I then divided in the same way I did before, and one week later two more were made.

On July 24 the hive containing the old queen was full once more, and I divided it that day; also quite a number of the old hives; and one week from that time many more were made. We had now come to a point where we could go fast, and the yard was soon full.

On August 28 we divided for the last time.

A large swarm for August.

We split seven of the strongest colonies right in two in the middle, as nearly as we could. Of course the larger part of the brood nearest ready to hatch was placed in the hives on the new stands, with the greater part of the worker bees. In this case we left the queens at home on the old stands. Of course all the old field workers would come back to the old places, and that was just what we wanted, because right here we safely introduced seven Italian queens of the J. P. Moore strain. The last colonies divided soon became strong.

When we had done dividing we found we had 31 colonies; but the queen of one of the hives was not laying as well as we believed she ought to, and so we killed her and attempted to introduce an Italian queen but failed. We then united this queenless colony with one of the weakest in the yard, which reduced the number to 30 colonies. I really believe that, if we had put young queens in the queenless parts as fast as we divided, we could have easily increased to 50 strong colonies from one.

Only 23 colonies can be seen in the picture; but there were thirty in all. Out of 21 colonies that Mr. Fort wintered out of doors by my system, 20 were alive last spring, and out of 9 that he put in the cellar, 7 lived through. The mice killed the two that died in the cellar, and he would have lost all in the cellar if he had not set traps and caught the mice. As it was, he had 27 strong colonies left last spring—a good showing for a beginner. One of these swarmed April 26, 1911. I doubt if this ever happened before in this northern county of New York (Rensselaer). Nineteen colonies were put in non-swarmer hives, such as I mentioned, and the remainder were run for increase. Those run for honey had to build all of the surplus combs and half of the combs in the brood part; but they gathered over a ton of honey.

Troy, N. Y.

INCH BLOCKS UNDER BROOD CHAMBER DID NOT STOP AN AUGUST SWARM

BY G. J. WIMMER

I am sending you a picture of a swarm of bees cast Aug. 22. You will notice it is quite a large bunch. My hand is completely covered with them, and they extend almost to the ground. The hive and supers from which the swarm issued was so crowded that I placed inch blocks under the four corners of the hive, and yet they were clustering all around the outside in large numbers until the swarm finally came out.

Nazareth, Pa.

AN INGENIOUS EXTENSION POLE FOR A SWARM-CATCHER

BY W. A. PRYAL

I am sending you herewith a photograph of our ingenious and witty friend S. A. Niver, now of this city, but until last year

S. A. Niver and his telescopic extension-pole swarm-catcher.

of Colerain, Wis. Mr. Niver worked my apiary last season after the beginning of April, and we secured a fair crop of honey, nearly all of which we disposed of at good prices. The apiary was increased and put in good working order for this season.

Mr. Niver reminds me much of our old friend the late J. H. Martin, known to your readers about a decade ago as "Rambler." Their make-up is about the same, save that the latter was not so tall by a good deal; and he is a great joker, as many who have attended Eastern conventions, which he probably graced with his presence, well know. But it is of him as an inventor that I started to write. Last season he brought out a number of new contrivances, possibly because he thought conditions here demanded some things different from what he used in the East. One of his labor-saving conveniences, and the only one I shall

Dividers like those used in the Aspinwall hive used in a double-story ten-frame hive, ordinary construction.

attempt to mention at length in this letter, is his trolley-pole telescoping hiving-basket for securing way-up-in-the-air swarms of bees. The photograph will make the whole idea clear. The basket fits into the upper end of the pole, and by means of the window-cord the basket is soon "histed" right under the swarm; and by means of a pole with a hook at the upper end the bees are jarred into the basket without any apparent trouble whatever. The wire-cloth container may be held near where the swarm has alighted, or it may be allowed to rest against a tree near by, and all flying bees of the swarm will soon join their fellows in the basket. Easy, isn't it? Another good feature about the contrivance is that the whole affair does not have to be lugged about the yard in one piece. The basket being easily removed, it is slipped from the pole, and the bees carried any distance, a cloth cover having first been pulled over them.

Oakland, Cal.

[If we are not mistaken, the original inventor of this extension pole was the late

Miles Morton, of New York State, a brother-in-law of Mr. Niver, alluded to by our correspondent. Full particulars in regard to the construction, dimensions, etc., of this swarm catcher, are given on page 173 of our Mar. 1st issue for 1899.—Ed.]

THE ASPINWALL NON-SWARMING PRINCIPLE APPLIED TO AN ORDINARY HIVE

Not an Entire Success, but Enough so to Justify Further Experimenting

BY A. V. SMALL

In the last edition of the A B C and X Y Z of Bee Culture there is a description of Mr. Aspinwall's non-swarming comb-honey hive. One feature of its construction is a movable side so that the brood chamber can be expanded laterally, thus making room for twice the usual number of brood frames. Three or four weeks before the swarming season, the sides are moved outward, and the brood frames are set about $1\frac{3}{4}$ inches apart. These spaces are filled with slatted partitions, or dividers, of the same size and shape as a brood frame. The slats are perpendicular, and are a bee space apart. This makes a large airy brood chamber with more than twice the ordinary clustering space. Mr. Aspinwall states that he has had no swarms from colonies kept in these hives.

Last summer I applied the Aspinwall principle to an ordinary hive by making ten slatted dividers the size and shape of a brood frame. The last of April I set another hive body on top of the brood chamber and placed half of the brood frames in each hive body, alternating them with the slatted dividers. Now, the brood chamber is composed of two sections—one above the other—each section containing five brood combs

The right way to assemble the Hoffman frame.

and five slatted partitions. This gives a big airy brood chamber, which goes a long way to make the bees contented. They cluster in the slatted dividers, and never hang out. There is so much space between the brood frames that the colony never feels crowded. Two comb-honey supers with shallow extracting frames on the sides were placed on top of the brood chamber. Half of the sections in the lower super contained combs partly drawn. It was in these that work first started, and soon spread throughout the super. The upper super was placed underneath when the first one was about three quarters full.

In this locality the flow depends on the weather, and the weather is very uncertain. If we start the bees in the second super before the first one is pretty well filled, we are apt to get more unfinished sections than full ones.

The experiment was tried with a rousing strong colony from stock that has the reputation of swarming twice a year. They got through the main honey flow in good shape. The ten combs were well filled with brood all of the time, and the colony stored a good surplus of nice section honey. About the first of August they built queen cells. In one I found an egg, and in another a young larva. These were destroyed; and as the hive stood in a very warm place I set one-inch blocks under the corners of the hive and slid the cover forward so that it rested on the back cleat. Plenty of ventilation is one of the best things I know of to keep down swarming, especially in very warm weather.

The colony thus ventilated built no more queen cells; and when smartweed began to flow they filled more sections, besides storing a goodly supply for themselves. The slatted dividers were removed, and the brood chamber reduced to one section as soon as brood-rearing began to slacken in the fall.

With this large airy brood chamber, with partly drawn combs in the lower super, and plenty of ventilation during the very warm weather, I think the tendency to swarm is no greater than that in a ten-frame two-story extracting hive. The queen is not discouraged in her egg-laying, with the result that there is always a strong working force ready to take care of any honey flow that may come.

While an apiary of such hives might not be practical, a little experimenting will do no harm, and may throw some light on the swarming question.

North Topeka, Kansas.

[This arrangement has been suggested before; but Mr. Aspinwall has not recommended it. Whether it would not accomplish the result sought at all, or would do so only partially, we can not say. If the slatted divider in alternation with the brood frames or section holders is the basic principle of his invention, then it would seem as if the same device, even though there were no extra slats back of the end bars, on the plan

here shown and described, would prevent swarming to a very great extent; and why not? The object of the slatted dividers is to prevent overcrowding of the brood nest. The bees, instead of clustering *outside* in front of the entrance, blocking the entrance (which ought to be wide open to provide for the necessary ventilation) will be *inside* the hive, where they can do some good.

It has been suggested that, when there is a lack of ventilation, the brood is liable to become overheated; that to prevent this the bees that are on the inside, where they should attend to the feeding of the brood, are forced outside; that the overheated or neglected brood and the idleness of the "house" force, if we may use the term, induces swarming. However this may be, we can not say. At all events, it is a fruitful subject for discussion.

We should like to hear from some of our other readers who may have tried the Aspinwall slatted dividers in the ordinary Langstroth hives. From the amount of inquiry that came in to this office about two years ago, asking if the device could not be used to prevent swarming in regulation hives, we should infer that some may have tried it. In the mean time, perhaps Mr. Aspinwall himself can throw some light on the plan tried out by our correspondent and why cells were started.—ED.]

A PRACTICAL WAY OF MAKING UP WINTER LOSS WITH A MINIMUM OF LABOR AND EXPENSE

BY E. D. TOWNSEND

What is the *best way* to make increase for one who runs about 25 ten-frame colonies for extracted honey? I have my nights and mornings principally for such work.

There are numerous plans in the bee papers and books, but usually there is an "or" in them, with a choice of some other way, and I should like a straight talk, with no "or."

Jefferson, N. Y.

G. W. HARRIS.

You will need to have your hives in readiness for the increase at the opening of the main honey flow, which will likely be from clover in your location. Here in Michigan, clover begins to produce honey any time between the 8th and the 15th of June, varying according to the condition of the weather during the spring.

The hives should be full of either drawn worker combs or frames with full sheets of medium brood foundation. We wire all our brood frames before putting in the foundation, seeing that the wires are drawn only moderately taut. The top wire can be drawn so taut as to sing some when picked with the finger. The two central wires should be drawn only until they are straight, while the bottom one must be left quite slack for best results. In fastening the foundation in the brood frames, be sure to see that the wedge is well seated in the sawkerf, otherwise the foundation with the weight of the bees adhering to it may drop out. Use an Easterday wire-imbedder.

As you are a carpenter you will likely have no trouble in nailing up the hives for your increase. In buying bees on Hoffman frames we found some of the end-bars had not been nailed on right. The V and flat edge of the end-bars should be nailed one way only. The illustration on page 278 makes this clear.

You have 25 colonies. As last winter was very hard on bees you will likely lose five of them. Five others may be too weak in numbers of bees to amount to much during the clover flow. This will leave fifteen strong colonies from which to make increase and get a fair crop of honey. At the very first signs that clover is beginning to yield honey, remove the fifteen strong colonies, and in their places put hives containing nine frames with full sheets of foundation, and one comb of brood with the queen from the old colony. Now place a queen excluder on top, then an upper story of extracting combs; then above this, as a third story, put the old brood nest. The tenth frame of foundation from the lower story can now be put in the third story to replace the brood comb removed.

When the bees surely have enough room without it, why is the middle story of extracting combs given at this time? I'll tell you, and this is a valuable "kink." We get the finest queen cells imaginable built in the third story. Were we to set this brood nest directly on top of the new swarm, as is customary, but few would build cells; but by isolating them up in the third story, separated from the brood by this story of empty combs, they do not hesitate to build lots of very fine queen cells.

Eight days after the division is made, the brood and queen cells in the brood nest at the top will be sealed; but as it is somewhat dangerous to handle queen cells at this age, and as we would prefer to have more bees hatch out of this old brood nest before making the final division, we leave them two days longer. On the tenth day, therefore, prepare as many bottom-boards upon new stands as you have made divisions, and remove the old brood nests—one to each of these bottom boards. When doing this, tilt up the bodies and look under for queen cells and mark upon the cover the number of frames containing good likely-looking queen cells for future use. There are usually some exceptions to the general rule, so we may expect that once in a great while no cells will be built, even when the brood is isolated, as I have explained. If one or two should be discovered without cells, go to one of the marked ones having frames with cells to spare, and exchange a comb of brood for one containing cells. This is the most simple plan of increase I know of; and any one with a season's experience ought to make a success with this method.

We will now suppose that you are not quite satisfied with the amount of increase obtained so far, and you want still more bees. All right. Locate five more bottom boards, the same as you did for the first di-

vision. (I would not do this until the next day after the first division, as this will give the old bees that you carried with your old brood nest to the new stand a chance to go home, so you will not have so many bees to bother you the next day). Place an empty body on each. Now go to five of your colonies marked "cells to spare," and remove a half of their combs containing about half of the brood and bees. One of the queen cells they contain should also go with each new colony. Now you have ten hives, each containing five combs of brood, and a good queen cell. Place these five combs of brood in the center of the hives from the five dead colonies I imagined you have, take their empty combs and fill out the empty space in these ten hives, and the work is done. It is all very simple; but be careful not to jar these ten-day-old queen cells too much or they will be spoiled.

If one has enough drawn combs, more of these brood nests can be divided provided there is a plenty of queen cells (and there usually is). If there is a buckwheat or fall flow these half-brood-nest colonies will usually fill up and have a plenty of stores for winter; otherwise they will have to be fed in the fall.

Later in the season Mr. Harris' medium-heft colonies will become strong and can be given upper stories for surplus honey. With this plan the colony on the old stand, containing the old queen, will do a "land-office business" in gathering honey after removing the brood from the top of their hive. All desire to swarm is taken from them with the removal of their brood nest, leaving them in that ideal condition so necessary for best results, i. e., free from the swarming fever.

In the above I have given our latest plan of making up our winter loss at our outyards. We simply go to the yard at the beginning of the clover or raspberry flow, make the first division, and give upper-story room to the rest of the yard for at least ten days, at the end of which time we make another visit. At this second trip the brood for our increase, and plenty of cells of the very best kind, are ready. With our previous plans, extra trips had to be made to provide queen cells for this increase. With this better plan, this is avoided; and, furthermore, it costs practically nothing to produce the queens, as the little colonies are so depleted of worker bees which have gone back to the old stand that there is nothing doing to speak of until new workers get old enough for field work, which will be ample time for the queen to mature and get to laying.

Remus, Mich.

Five Swarms from One

Last year my bees commenced to swarm June 23, and five swarms in all issued from one colony. The first swarm came out three times; the second one, twice; the third one, once. Can you beat this?

La Grange, Me.

E. A. DAY.

[That is quite a record, to be sure; but, at the same time, it is rarely a good plan to allow after-swarming. If you desire increase only, it would be better, in most cases, to make it artificially.—ED.]

MAKING UP WINTER LOSS

Rearing Queens in Upper Stories by the Alexander Plan

BY G. J. YODER

Since 1875 I had used the nucleus plan for queen-rearing, generally having two compartments for a queen in a hive; but when the Alexander plan came out it was so satisfactory that I abandoned the nucleus plan.

Several years ago we had a great spring loss; but we rallied, and bought bees until we had 60 colonies at the home yard. We had 150 sets of brood combs on hand, many of which were full of honey; and as soon as a colony was strong enough a full set of worker combs, partly filled with honey, was given, the queen having access to both stories. This soon resulted in very strong colonies, some of which were managed on the Alexander plan for rearing queens; while in case of the others the upper story was removed about the time the colonies were preparing to swarm—from one to three supers put on with full sheets of foundation fastened at the top and two sides, then a queen-excluder, and finally the upper story on top of that. This latter was left on until the bees were nearly all hatched, and we found that many of those having upper entrances, made by leaving out a part of the cleat at the back corner of the excluder, had matured queens. In the meantime, the bees had been drawing out the foundation in the supers below, and storing honey. At this point we removed the upper story, containing the new queen, thus making a new colony. Or the old queen was removed from the brood-chamber below, and the young queen reared in the upper story substituted, and this upper story placed on some other colony that had no supers. Years ago I tried raising queens in upper stories but failed.

By the fall of 1906 we had 150 colonies instead of the 60 we had started with in the spring, and we had secured an average of 125 lbs. to the colony, spring count, about half of which was extracted honey. We also had 40 sets of worker comb all the way from half full to full of honey. We uncapped these a little more than half way up from the bottom bar to the top bar, and ran them through the extractor. We were thus ready to make another trial the next year.

In the spring of 1907 we had less of a loss; but we soon put into operation the same plan that gave such good results the year before. We had more queens raised in upper stories than during the previous year, and all those upper stories that we set on new stands in the fore part of the season worked in supers during the last flow. I noticed in particular that the colony that raised the first queen that I put down in the lower brood-chamber gave 178 sections of fine honey.

I may be wrong; but I attribute the success in rearing queens in upper stories by

this plan to the distance between the two brood-chambers, and to the fact that the colonies were so strong. Removing the upper stories before many sections were capped also had a good deal to do with it. I prefer select cells built under the swarming impulse, which are generally very plentiful, and come at just the right time.

Some are not successful with the Alexander plan for rearing queens in upper stories; but in this locality it certainly works finely, especially if there are plenty of brood combs on hand. We went through these two very profitable honey seasons without a nucleus, and with much less work than would have been required by the old way.

Meridian, Idaho.

[It will be seen that our correspondent touches on the point brought out by Mr. Townsend in another article in this issue; that is, that bees rear queens more promptly in upper stories if these upper stories can be separated some distance from the lower stories, so that the brood is somewhat isolated. The plan of rearing queens in upper stories has much to commend it, and very likely much of the trouble heretofore has been caused by the upper story being too close to the lower one—the one containing the queen.—ED.]

PUTTING ON SUPERS

Should the Empty Super be Placed Below or Above the One Partly Filled?

BY DR. C. C. MILLER

When considering management of supers it makes some difference whether we are talking about section-supers or extracting-supers. There are general principles that apply alike to both kinds of supers. If a super of either kind be put under full or partly filled supers, the bees are likely to begin work on it sooner than if the empty super had been put on top. Also, the further a super is above the brood-chamber, the less danger there is of the bees carrying bits of dark wax from the brood-combs to put on the cappings in the super. It will be seen, however, that, while these things are alike true for both kinds of supers, they do not make the same difference in one kind as in the other. Generally an extracting-super is filled with drawn-out combs that have been used before; and if such a super be put on top the bees will begin work in it much more readily than they will in a super of empty sections. The bees will darken the cappings near the brood-chamber in either kind of super; but dark cappings are very objectionable in sections, and not at all objectionable in extracting-combs. So it will be seen that Mr. E. D. Townsend, with his extracting-supers, cares nothing about dark cappings, and not so very much about hurrying up the bees at beginning work in the new super.

Yet, even with extracting-combs, the bees will commence work at least a little sooner

if the super be added below, and Mr. Townsend is making a mistake in his management unless he has some other reason for it. I think he has a very good reason. As he explains it, if he puts the empty super under, unless an excluder is used the queen will often go up and lay in the super. If he puts the empty super on top, the queen is not likely to go up through the partly filled super to lay in the empty one, neither is she likely to occupy the super already occupied with honey. So he saves the expense and the bother of excluders, and that over-balances the gain there might be in putting the empty super under.

With section-supers, the practice varies all the way from never having more than two supers on at a time and always putting the empty super on top, to having six or eight supers on at a time, and always putting the empty super under. The argument of the former is that, when the bees are crowded down to two supers, they hurry up the finishing, giving less time for darkening, and resulting in fewer unfinished sections. Those, however, who use this plan successfully, use pretty large supers, which makes a difference. An objection to the plan is that, if you crowd bees so as to hasten the finishing, you are doing something that will at the same time be an inducement toward swarming.

Let me now refer to my own practice with section-supers, without saying by any means that I know all about it, for I've been all the while learning, and, likely enough, may make some change next year. Besides, there are times when it's a good bit a matter of guessing as to what is the best thing to do.

One thing I want is to have lots of room—not merely plenty of it, but abundance of it, so as to have whatever advantage there may be in abundance of room to prevent swarming. If there are bees enough to fill six or eight supers, then why not give them? Another desirable thing, as already intimated, is to get the bees started as soon as possible on the new super, and that means that, *generally*, the added super will be put under. It may be sometimes that there is a question as to whether the bees shall swarm or not, the thing being so near on a balance that an added super shall have the deciding vote, the vote being for swarming if the super is above, and against swarming if it is below.

To hasten the start in the super, a bait section is the thing. Bees seem to start on it just as soon as they would start in an extracting-super. In a poor season I've had the bait sections filled and sealed, all over the apiary, and not a section of foundation drawn out beside.

The second super will usually be put under the first about as soon as the first is half filled. If the season be poor, and the bees are making slow work on the first super, it may not be worth while to give any second super. If the season be very good, with every prospect of a big harvest, the second su-

per may be given before the first is half filled. Indeed, it may be given when only a fair start is made in the first. If there are bees enough to fill the two supers, they may as well fill them. It seems as if the harvest should be a trifle greater than if the bees do any waiting for room. With a strong colony and strong prospects, not only may an empty super be put under the first, but an empty super may also be put on top of the first super. I have practiced this putting an extra empty super on top for only a few years, but so far I like it well. It acts as a safety-valve. It may happen that the bees need it, and it's there ready, and the bees can take to it whenever they feel like it. If they don't need it they can let it alone.

Suppose, now, we have on each strong colony three supers. When the bottom one is half filled—sooner or later according to the strength of the colony and the prospects—the top super will be put down at the bottom. In a few cases this top super which is now put below will have a start made and some honey in it. This shows that it has done good, and without it the bees would have been crowded to their harm. Most of the top supers, however, that are now put down will show no start in them. Yet, even so, the bees have been in them a little; and when put down the bees will probably take to them just a little sooner than if they had not been on at all.

There is another reason for having that extra empty super on top. It gives more room, and the supers are a little cooler on a hot day. The bees have a comfortable feeling that they have all the room they want, and will be less inclined to think of swarming.

Still another reason: After an empty super has been on top a few days it may look as if the bees had never touched the foundation, none of it being drawn out; but if you look closely you will see that they have made more secure the fastening of the foundation to the topbar of the section. Occasionally a starter may be so lightly fastened that a full force of bees suddenly thrown upon it would break it down. The bees will fasten this securely before it is put down. Even if there should be a breakdown in the top super, it will have no honey in it, and will not be as bad as a breakdown below.

When the top super is put below, a fresh empty super is put on top. This course is continued till near the close of the harvest, the top super being put below as fast as it is needed, and a fresh super put in its place. Of course each super is taken off as soon as finished—often quite a little before all the sections in it are finished, but while the corner ones are not quite finished, and perhaps a few at the sides. The unfinished ones are assembled in a super and returned to be finished. In a good season there will be on some hives as many as seven supers at a time, and they will be all full of bees with the exception of the top one. It seems as if the harvest would be at least a little less if the bees were crowded into smaller space.

When it appears that the harvest will soon close, the top super is not put down. It is left on top where the bees can work in it if they really need more room. There is less danger then that crowding will induce swarming, and swarming thus late will not interfere so much with the harvest.

I have tried putting the most advanced super further down from the top in order to have it finished sooner; but I'm not certain there is any thing gained by it. The bees finish about as fast on top, and a super that has from two to five supers under it is not likely to have its sections darkened by bits of dark wax from the brood-combs.

Marengo, Ill.

LESSONS LEARNED FROM MISTAKES IN BEE-KEEPING

The Danger of Trying to Make Increase Too Rapidly

BY W. A. DUNTON, M. D.

Mistakes have often been more instructive for the guidance of others than proper procedures, because, when all the dangers are known, it is easy to steer clear of them. That others may profit, I will relate a few of my own mistakes in beekeeping.

Much of my trouble was caused because of an eager desire to increase the number of colonies too rapidly. I divided one of my best colonies by removing four frames, bees and all, to a new location. I intended to leave the queen on the old stand; but, instead, I took her with the nucleus. The result was that the old workers returned, and she was left with too few bees, and it required a long time to build up again. The honey-flow being good, and the bees in the old colony very numerous, they built drone comb rapidly, even on the lower half of full sheets of foundation. They made ten queen-cells on one comb besides several on another. Here was my opportunity. I shook off every bee, carefully cut out the queen-cells, fitted two into each of four combs, made five nuclei of two combs each, with all adhering bees, placed each comb containing the cells between the other two in each nucleus, closing the entrance with grass in accordance with the Somerford plan.

One lot was suffocated; two others lived, but built no queen-cells, while two only, out of the five, raised queens and lived by dint of constant additions of brood and honey.

Examining them I found all ten of the queens dead (I had shaken them to death while so carefully removing the bees before cutting out the cells).

HOW LAYING WORKERS WERE GOTTEN RID OF.

The bees of one of the two that hatched queens became excited one day when I opened them, and killed their queen before she had laid an egg. Discovering this a few days later I gave them a frame of brood from which they hatched another queen.

This queen was killed in the same manner. I gave them another frame of brood, and they capped over all the brood but started no queen-cells.

On my next visit I found a few eggs scattered around irregularly over two of the combs. Thinking this was something new I examined them again in a week, and the cells containing the eggs had been raised up into drone-cells; and the fact that I had laying workers slowly dawned upon me. I shook every bee out of the hive, 200 feet away, and then gave them another frame of eggs and brood. They refused to raise a queen, and the drone-eggs kept coming. I then united them with another colony, and had no more trouble.

MUTILATED DRONE BROOD LEFT IN THE COMBS.

I had a good colony which had been taken from the side of a house with great difficulty, and which had been installed in a hive with a superful of full sheets of foundation drawn out and partly filled with honey. The brood-chamber was full of brood, and every thing was booming. "Now is the time," thought I, "to make two colonies out of one." I gave the super to the colony on the old stand, carefully shook off all the bees except a few young ones, shaved off the heads of all the drone brood, and turned the new hive at right angles to the old hive.

In two weeks they had reared a queen, and the hive was packed with bees, but there was no honey. The drones had putrified in their cells, and the young bees had not been able to carry them out. The odor was suggestive of the smell of a fertilizer factory. However, in time they cleaned all the cells and the hive was sweet again. Just at this time the nectar failed and I had to feed both colonies.

A LARGE SWARM LOST.

In another apiary five colonies were placed close together, two of them above the other three. I moved one of the upper ones away, and the returning bees went into the strongest of the lower colonies that was already full of bees, and two days later a large swarm departed for parts unknown. The removal of three or four frames of brood from the strong colony would have saved my nice swarm; but that is another example of one of those touching events in human life mentioned by Whittier in his poem "Maud Muller"—"it might have been."

TOO MUCH ROOM A DISADVANTAGE.

Shaking all the bees from the combs of a strong colony I placed the brood over a small queenless stock. However, the honey-flow was poor in that vicinity, and the bees had twice as much room as they needed all summer. They should have been given four frames of brood, and treated as a nucleus in a single brood-chamber without a super.

I gave supers to several weak colonies, and thereby put the bees back by giving them too much space to keep warm, thereby curtailing brood-rearing.

COMBS MELTED DOWN.

I made a nucleus of four frames of brood without bees enough to protect the combs. As the hive was not properly shaded, the combs melted down, the larvæ were cooked by the heat of the sun, and the bees were dead in a heap on the bottom of the hive.

VIRGIN KILLED LAYING QUEEN.

I had a small swarm from a nucleus, and put it back without killing one of the queens. A few days later I found drone-cells built from worker comb; and as they occupied a compact little space in the center of one comb I concluded that my remaining queen was probably not impregnated, so I placed the hive over a strong colony, and evidently the bees did their duty, as that colony is booming to-day.

NO HONEY LEFT IN THE BROOD-CHAMBER.

In July I found one super full of honey, and I removed it. A few days later I lifted that colony to see how much was in the brood-chamber, and found that they had no honey at all, having depended upon that in the super. The nectar failing just then, I had to feed them.

In September I examined a super and found from 20 to 25 lbs. of nice honey. I went out there a week later to get it, and in place of the fat combs of honey I found them almost empty. The handling had disturbed and alarmed them; and in order to assure themselves of its safety they had removed it to the brood-chamber. Truly, as Burns says,

The best-laid plans of mice and men
Gang aft aglee.

I have said nothing about any of the "smart" things done with my bees, as these notes are supposed to relate only to my mistakes, which I hope may be of some slight service to my brother novices in bee culture.

Los Angeles, Cal.

A SWARM THAT DID NOT CLUSTER

BY WM. GRAMS

In Siftings for Dec. 15 mention is made of swarms not stopping to cluster. This seems to be an unusual stunt, and so I should like to tell of an "experience" which I had last July.

As a building contractor I went about three miles into the country to bid on a small country schoolhouse. Bids were received at the clerk's farm. The clerk, an old Scotchman and an old acquaintance of mine, had gotten a hive of bees from me some ten years previous; but from lack of attention they had not increased, for the reason that all swarms that ever issued went off. The people at the farm were sure that some of the swarms had gone off without clustering. I thought, of course, that they had not seen them. At any rate, after three years there was only one stand of bees left; but there was an empty hive

there which had always been ready to put the new swarm in.

As soon as I came to the place my old friend took me out to see the bees. It was an ideal place among the fruit and shade trees, where there was plenty of room to fly. He asked me if I thought that they had already swarmed and gone off, as usual, or whether they would swarm soon. I really did not know. Of my twenty colonies, not one had swarmed up to that time. The hive was crowded with bees. I told my old friend that, judging from the number of bees in the hive, they should have swarmed before, but that it might be that the queen got lost in the attempt to swarm, and that possibly, as soon as they were ready again, they might come out. I had to explain, as usual in such a case, what I meant by getting ready, which I did to him and half a dozen others who were then waiting for the opening of bids for the schoolhouse.

We were all in a room ready for this occasion not ten minutes after looking at the bees, when some one came in and reported that the bees were going off. We went out just in time to see the last of them going over the tree-tops. The boys followed them which was easily done, for it was such a large swarm that there was a cloud of bees. They followed them while I got the hive ready.

The bees went about half a mile and then began to circle around a large scrub oak. I had the hive ready by that time, and about a dozen of us went over to the tree with the empty hive into which I intended to hive the swarm after it had clustered. When we reached the tree, most of the bees were still flying around; but many were alighting on the trunk of the tree, where I found a hole about three inches in diameter, about four feet from the ground. The bees were running into this hole at full speed, without clustering. I had the hive; but there was no chance to do any thing with it. They were running into the hole so fast that I supposed the queen had already gone in; but I continued to watch the mass of bees as they ran from the ground up toward the hole. To my surprise I found the queen, a fine specimen, and with a lucky twist I caught her firmly by the wings and showed her to the crowd, with the statement that I thought this must be an after-swarm, and that, as there was only this one queen with the swarm, the bees would return to the old stand, which they did.

I caged the queen, put the new hive on the old stand, and in a short time all of the bees were in the new hive on the old stand. I must confess here that my experience with bees is not so extensive that I could tell whether the queen that I took from the swarm was a virgin or a laying queen. She seemed to me very slim. But the main thing was that the bees came back.

These bees surely did not cluster, nor did they make any attempt to do so; for all of this occurred in about an hour.

Sturgis, S. D., Jan. 5.

Heads of Grain from Different Fields

Swarms Issue Before Cells are Sealed and After Queens are Hatching

In the summer of 1910 I had 34 colonies, spring count, located in a young orchard on a north slope. There was very little swarming until July 4; but from then on, swarms issued to about Aug. 1. In a majority of the cases I examined the parent colony after the swarm issued, and in almost all cases found that young queens had already issued or were gnawing their way out. In a number of instances the virgins came out while I was transferring swarm cells to queenless colonies. I well remember my first experience of that kind. I cut out a fine cell from a hive where a swarm had just issued, and laid it on a bit of board in the shade of a hive while I was cutting out another and closing the hive. When I looked at it again a bee was crawling all over the outside of it, and it was empty. I thought it could not be a queen, because it had not had time to hatch; but when the same thing was observed again, I "tumbled."

In the summer of 1911 I had my bees on a south slope with very little shade, and that from boards laid over the hives. Bees began swarming during the early part of June, and kept it up actively till the last of the month. By that time it was getting dry, and the previous abundant flow of honey was tapering off. My previous year's experience led me to suppose that swarms do not generally issue until young queens are ready to come out; but that season it was just the opposite. When I went through parent colonies I found a majority of the queen cells still unsealed, and had difficulty in getting any number of sealed cells from my best colonies to use in raising queens. I think all cells opened in hives from which swarms had just issued showed the queen still in the grub stage—at least none were ripe, so far as my memory serves me. It completely upset my previous year's experience.

Rains came about the middle of July, and the fall flow was good. About the first of August, swarming began again and continued up to the 15th of the month. About ten or fifteen per cent of the colonies swarmed at this time. As in June, the bees again seemed to be swarming long before their queen cells were ready to hatch. Probably, taken as an average, my bees were not quite so well provided with storage room in 1911 as in 1910. In 1911 they were also more exposed to the sun.

But allowing for the two above-named differences I am myself inclined to charge the difference in haste to swarm more to the difference in the season and honey flow of the two years.

Pellston, Mich.

J. D. ROBINSON.

Clipped Queens Not a Nuisance

The thought has often occurred to me that beekeepers have a great advantage over those who handle other live animals because of the uniform action of bees under certain conditions. It seems to me that we should know just what bees will do if treated in a certain way; and yet, was there ever a business in which there is so much disagreement among the masters of the craft?

Some claim that clipped queens are a "nuisance." I can't see it that way, for I have clipped all of my queens for the past 25 years, and I can not recall that in all that time a single queen has been killed or injured by the bees on account of having been clipped. I always cut off about two-thirds of both wings on one side, and my bees hardly know what a queen would look like having both wings whole. Of course, queens reared in the fall keep both wings until clipping time in the spring, which is just as soon as I can handle them without exposure to cold. I clip to save time, work, and swarms. I am sure that I have saved a great many dollars' worth of bees by having all queens clipped. I admit that, if I were using very large hives, and had my fields all overstocked, it is likely that clipping could be dispensed with. Under such conditions there would be very few swarms. But the average beekeeper will save much work by clipping. My hives are all placed close to the ground, and during the swarming season I keep the grass mown smooth around the entrances. When a swarm issues, the attendant can usually find the queen as soon as she leaves the hive.

I often pick up a queen, cage her, set the hive (from which the bees are still issuing) back a few feet with the entrance reversed, put a burlap over it, and, after placing a prepared hive on the old stand, put the caged queen in the entrance and go about other work, not having expended more than thirty seconds of time, well knowing that the bees of the swarm will return to the old stand reasonably soon, whether they cluster or not.

H. E. Harrington, page 143, March 1, says that he had to break off limbs and climb trees "just the same." I can't see why. I clip to avoid climbing trees and sawing limbs, and I do avoid it. My only failures have occurred where colonies that were supposed to have clipped queens had superseded and reared young queens. This happens only once in a great while. If you are sure your swarm can not combine with another that has a flying queen, or that they have not a virgin queen with them, you may rest assured that they will come back in due time. In cases where several swarms issue at nearly the same time, and all cluster together, it is an easy matter to divide them up and distribute them where wanted, if all of their queens are in cages. Possession of the queen is the key to the whole situation; and for my part I would not think of working without this advantage; but, as I intimated at the start, it is much easier to get the bees to agree on a certain course of action than to get any sort of agreement as to methods of procedure on the part of the men who handle them.

My son, who was practically reared in the apiary, says he never knew of a queen being injured by her bees because she was clipped.

Bridgeport, Wis., March 14. HARRY LATHROP.

How to Find Where the Swarm Came from

Going out into the beeyard one day recently, I found three swarms hanging clustered. That evening, just before dark, I called my son to assist me in finding where the swarms had come from, as I always like to learn this; and my plan works so nicely, and is so little trouble, I feel as if I should write it up for the benefit of others.

I have boxes of $\frac{3}{8}$ stuff, $3\frac{1}{4}$ inches wide by 5 high, and $5\frac{1}{4}$ long inside, with the bottom nailed fast. A $\frac{1}{2}$ -inch hole is bored in one end, and covered with wire cloth for ventilation. The top is the same width as the outside of the box, but an inch or two longer. A $\frac{1}{2}$ piece of board that is a little smaller than the inside of the top of the box is nailed on the bottom of the cover to keep it from slipping off.

When hiving one or more swarms I put about a teacupful of bees in the box and set it in the shade, and mark which swarm the bees are from. About sundown, or later if the bees work late, they are jarred down to the bottom of the box by setting it down hard. I lift the top off and dust enough wheat flour on the bees in the box to coat them lightly. I then dump them out on a hive cover; and if they do not fly readily they are dumped again on the ground. They will soon return to the old hive; and if there are several "boxes" to locate, an old sack can be thrown over the entrance and another box dumped, bees located, and so on until all are disposed of.

In order to work well the bees should be confined away from the swarm for a few hours. If the swarm has issued the same day, they are all right. If liberated while bees are flying freely they seem sometimes to be confused, and will try to enter other colonies, especially where young bees are playing. So, after the yard has quieted down toward night is the best time. But if the yard should quiet down before a rain, or if it should turn cool, the bees will go home just as well. Do not wait until nearly dark or the bees may not get their bearings. Too much flour makes the bees slow. It is easier if there is some one to find which hives the bees are entering.

Port Orange, Fla., March 26.

Italian Bees Swarm Excessively

W. C. Mollette, Feb. 15, 1912, p. 100, complains of the excessive swarming of Italians. Many in this vicinity have had the same difficulty with Italians. A neighbor of mine who found a bee-tree asked me to assist him in cutting it and hiving the bees. The

following year they swarmed three times, and the first swarm also cast a swarm. Almost everybody here prefers black bees because they do not swarm so often.

CROSS BETWEEN ITALIANS AND BLACKS DESIRABLE.

I try to keep a cross between Italians and blacks, as I think they are superior to the Italians, and they seem to be the best all-around bee for this locality. I have a black queen three years old that was mated with an Italian drone, and I never saw better hustlers than her bees are; and as to their disposition, they are the quietest ones I have.

Webster Springs, W. Va.

L. S. WEESE.

Mr. Editor:—Will you please answer these questions for me?

1. Is it important to wire the brood-frames when starters are used?

2. I wish to make an increase this summer. Will you give me the best method? What month is best for this?

3. I bought three hives of bees during the past winter. The supers are on them, and they contain some honey. Should I take them off now, or will the bees use the honey this spring in brood-rearing?

4. What time should supers be put on the hives? White clover begins to bloom about May 10 to 15 in this locality.

5. I have some transferring to do during fruit bloom. At what time of day should this be done? Could I take the virgin queens that I catch at the second drive and introduce them to a frame of brood from some other hive to make increase?

6. Do you think I could produce comb honey without the use of separators?

7. When is a good time to paint hives?

8. Should the hives stand perfectly level or slant to the front?

Boring, Ky., March 22.

JESSE WOODWARD.

[1. It is almost as necessary to have wires when starters are used as full sheets. In fact, we do not see how any up-to-date beekeeper can get along without wiring his frames. The cost of the wire is insignificant when compared with the saving in the breakage of combs while handling or doing extracting. Without wires, combs (whether from full sheets or only starters) have a tendency to sag after they are drawn out, even though all the cells are worker at the start; and this sagging renders them unfit for worker brood.

2. In this issue you will find several pretty good methods for making increase explained. The Alexander plan has been spoken of very highly. It is as follows: When your colonies are nearly full enough to swarm naturally, and you wish to divide them so as to make two from one, go to the colony you wish to divide. Lift it from its stand and put in its place a hive containing frames of comb or foundation, the same as you would put the swarm in providing it had just swarmed. Now remove the center comb from this empty hive and put in its place a frame of brood, either from the hive you wish to divide or some other colony that can spare one, and be sure to find the queen and put her on this frame of brood in the new hive; also look it over very carefully to see that it contains no eggs nor larvae in any queen-cells. If it does, destroy them. Now put a queen-excluding honey-board on top of this new hive that contains the queen and frame of brood with their empty combs, then set your full queenless colony over the excluder. Next put in the empty comb or frame of foundation, wherever you got your frame of brood, and close the upper hive except the entrance they have through the excluder into the hive below. Now leave them in this way about five days, then look over the combs carefully, and destroy any larvae you may find in the queen-cells unless they are of a good strain of bees that you care to breed from, for they frequently start the rearing of queens above the excluder very soon after their queen has been placed below the excluder. If so, you had better separate them at once; but if they have not started any queen-cells above, then leave them together ten or eleven days, during which time the queen will get a fine lot of brood started in the lower hive, and every egg and particle of larva that was in the old hive on top will have matured, so it will be capped over and saved; then separate them, putting the old hive on a new stand. It will then be full of young bees mostly, and capped brood, and in about twenty-four hours they will accept a ripe

cell, a virgin, or a laying queen, as they will then realize that they are hopelessly queenless. We would advise you to give them a laying queen, as we never like to keep our full colonies for even a day longer without a laying queen than we can help. In this way you have two strong colonies from one, as you have not lost a particle of brood nor checked the laying of your queen; and with us it almost wholly prevents swarming. This is the way we have made our increase for several years, and we like it much better than any other method we ever tried. In doing so you keep all your colonies strong during the whole summer, and it is the strong colonies that count in giving us our surplus.

As to when is the best time to make increase, it all depends on conditions. If you desire a honey crop, make increase *after* the honey-flow. At such time it will usually be necessary to practice stimulative feeding. If increase without reference to a honey crop is sought, then we would start dividing along about the last of May. When increase is being made in the spring or early summer, it is usually not necessary to feed.

3. If the supers contain sections partly filled, take them off. If they contain extracting-combs, and stores are scant in the brood-nest, leave them on. Better still, select out the light combs in the brood-nest, and put in their stead heavy combs from the super and then confine the bees down to one hive body.

4. Supers should be put on the hive about the time the bees begin to whiten the tops of the combs after the honey-flow begins. Honey does not begin to come in until about a week after the first clover begins to come out, so that you will need to put on supers somewhere from the 20th to the 25th in the average season; but better not go by the calendar but by the season.

5. We would select any hour in the day between ten and two o'clock. If possible, do the work in a sheltered location away from the wind, as some brood is liable to be chilled while being transferred.

Yes, you can catch the virgin queens at the same time, as explained.

6. You can produce comb honey without separators, but it is very unwise to do so. When separators are used, comb honey will bring anywhere from one to five cents a pound more. It is never economy to try to get along without them. If there could be a general law to compel all producers to use separators, it would be much better for the comb-honey market.

7. Usually after the honey-flow when work is slack.

8. Hives should slant to the front, so that water will run out of the entrances after a beating rain.—Ed.]

Ohio Convention Report

The annual convention of the Ohio Beekeepers' Association was held at Springfield, Feb. 21. The association was favored with the presence of Dr. E. F. Phillips, of the Bureau of Entomology, Washington, and Chief Inspector N. E. Shaw, of the Department of Agriculture, Columbus. Mr. Shaw delivered a very able address on bee diseases in Ohio, which was highly appreciated.

Mr. E. R. Root and Dr. Phillips at the evening session gave addresses illustrated by the stereopticon, which were very instructive and interesting.

Mr. Henry Reddert read a paper during the day session on sweet-clover forage in and around large cities, which provoked considerable comment.

Mr. E. R. Root's talk, entitled "Recent Developments on the Wintering Question," was well received and discussed, as was Inspector Beard's paper entitled "What has been Accomplished by Inspection."

The following officers were elected to serve during 1912:

President, D. H. Morris, Springfield, O.

Vice-president, J. G. Creighton, Harrison, O.

Secretary, N. E. Shaw, Columbus, O.

Treasurer, C. H. Weber, Cincinnati, O.

The following is the Executive Committee:

A. N. Noble, Springfield, O.

Glenwood Beard, Magnetic Springs, O.

E. R. Root, Medina, O.

J. W. Arthur, Springfield, O.

C. E. Leavitt, Mechanicsburg, O.

Fred W. Hammerle, Hamilton, O.

The next meeting will be held in Columbus.

A. N. NOBLE, Sec.

Our Homes

A. I. ROOT

Beloved, let us love one another: for love is of God; and every one that loveth is born of God, and knoweth God. He that loveth not, knoweth not God, for God is love.—1. JOHN 4:7, 8.

The point I wish to consider in the above text is the expression, "God is love." Somebody has said that "love is God." What is love in the above text? We often speak of people being in love—a boy or a girl, a man or a woman. This affection between the sexes *should* be love; but how often it is a very poor excuse for real love! Our newspapers are full of tragedies that come from what is called love. A man says he loves a woman; and because she will not love him or will not marry him, he kills her and then perhaps commits suicide. Is there any real love in such a transaction? Far from it; and when we get right down to it, the love between the sexes is, as a rule, but a poor low kind of selfish love.

It *may* be, and God intended it *should* be, one of the highest attributes of the human family. It should be one of the most sacred and ennobling things that we meet with in this world of ours. It is, in fact, the foundation stone in building up the human race and Christian character.

The divorcees that are getting to be so popular, and that we hear so much about, are results of this low kind of love, or only a selfish love. The love mentioned in our text is very holy and sacred—the very opposite of selfishness. God's love is for all humanity—good, bad, and indifferent. The love between the sexes, of which we have been speaking, is oftentimes, as I have said, but selfishness. Real true love, divine love, as spoken of in our text, is sacred and holy, and should result in doing good to *everybody*, lending a helping hand wherever an opportunity offers.

Some of our leading agricultural papers are doing quite a little lately in disclosing frauds, and they are, without question, helping humanity greatly. Our own journal (through your humble servant) as you may be aware has done quite a little along this line, and I have prayed most earnestly that God might help me to do my criticising with "love" in my heart and in a Christian spirit. While having this matter in mind I ran across the following clipping which I make from the *Sunday School Times*. I wish you would read it over, and then read it again:

THE POISON OF CRITICISM.

Critical thoughts and words are usually unloving. Therefore such criticism is poisonous—always to the one who expresses it, and often to the one who hears it. But it is so popular! Try to live one day without speaking a critical word or thinking a critical thought of any human being, and see if the habit of criticism has not been popular with you. Test it as you listen to the conversation of others—but don't criticise them if you find it is popular with them! Love them out of it instead. Only love will crowd criticism out of ourselves. And we need to be cleansed and purged of it wholly, completely, and for ever. It is so subtle, so inviting, so spon-

aneous, so attractive, so devilish, and so deadly! Our sin-habituated natures are so shot through and through with this poison that only a miracle of change can help us. Christ will work the change. When he is overwhelming us with his infilling presence, we do not poisonously criticise; we cleansingly love.

The above almost startled me when I first read it. I said mentally, "Thank God for this kindly warning when perhaps I needed it most." God knows there *is* great need of kindly criticism of the way many men, especially evil-disposed men, are doing business in this world. I know by experience how hard a matter it is to show up fraud and injustice, and do it always in a Christian frame of mind. The loving and dear Savior said, remember, "Love ye *your enemies*, do good to those that hate you." It almost startles me yet when I think of what is implied in those wonderful words. Years ago I told my good old mother that those words came from heaven, and were heavenly and not of earth. Let me give you a little practical illustration. Some days ago I sent to a great seedhouse for some garden seeds. Among other things I ordered some Golden Bantam sweet corn and also a like quantity of black Mexican sweet corn. I planted two rows of the Golden Bantam, and it came up promptly, almost every seed germinating. The third row was planted to the black Mexican, and scarcely a seed germinated. In ordering some more seed a few days later I mentioned my trouble with the black Mexican corn, and suggested that I thought they ought to know about it. No reply came. Some time later I had to mention that some of my order had not yet arrived, and spoke again of the black Mexican corn that would not germinate, and asked if some sort of reply should not be given me. After waiting a little time, and not hearing a word, I turned to their seed catalog and found the following note of warning or contract between themselves and the purchaser.

While we exercise great care to have all seeds, bulbs, and plants pure and reliable, we do not give any warranty, express or implied. If the purchaser does not accept the seeds on these terms and conditions, they must be returned at once, and the money that has been paid for the same will be returned. We can not afford knowingly to sell seeds doubtful as to vitality or purity. We test our seeds before sending out, and should they prove defective in germination or purity when properly planted and cultivated, we will refill the order free or refund the price paid.

I read it over and felt provoked, and decided it would be no more than fair to present the whole matter in our journal and discuss it in regard to the responsibility of seedsmen. Then I thought of the passage I have quoted from the *Sunday School Times*, and asked myself the question, "Is there nothing in my heart but love for these seedsmen, prominent seedsmen, who issue great nice catalogs, and have always enjoyed a good reputation?" Is there nothing but

love in my heart for these friends of mine (for I am sure they are my friends), while I think of publishing a protest against their warranty of their seed? A little later I decided to make still another trial of the Black Mexican sweet corn. I took it away on another part of my grounds and planted a long row. Almost every kernel germinated. Perhaps the weather was more favorable; but why did the Golden Bantam germinate so freely while the Mexican at first trial did not germinate at all? I have been thinking that my helper, Wesley, *may* have put a larger quantity of fertilizer on this black Mexican corn than he did on the Golden Bantam. Notwithstanding this, I *do* think the seedsmen should have made some reply of some kind; but my letters and orders were sent in at their very busiest time. Perhaps I should explain that my complaint about the Mexican seed corn was put on a separate sheet of paper so it could go to the proper one to consider. Never mind; my order went in at their very busiest season. Then I reflected that most of us do live "in glass houses," to use a familiar expression.

Just a few days ago I sent to The A. I. Root Company for a pound of Japanese buckwheat to be tested on my Florida grounds. When it came I made a protest because the package, which came by mail, contained quite a little chaff and dirt and other stuff, increasing the postage, and being of no use whatsoever. Of course this was the result of some careless clerk. If no one else received a like package of this, why—it was a very lucky chance that this one came to myself. It was the result of somebody not doing his duty. He probably scraped up the last bit in the bottom of the bin for myself, carelessly neglecting to use a sieve or something to take out the chaff. Now, I think it is certainly right to complain and tell when things are not just as they should be. Where there is a flaw in the matter that can be easily remedied, it should be before others are served in like manner. Unless you have had experience in showing up frauds, showing up irregularities, lack of care, etc., you hardly know how difficult it is to adjust all these matters in a loving and kindly feeling toward poor struggling humanity.

Years ago, in my childhood, I saw a little poem that had a couple of lines that run something like this:

Let love through all your actions run,
And all your words be mild.

The *Sunday School Times* suggests that only the love of Christ in our hearts can help us to avoid and keep away from this habit of unkind criticism. I do sometimes try to restrain hasty and severe criticism. A great many times I have put in a word in favor of the one who is under discussion. Oh! I wish that all would try to cultivate that spirit that "thinketh no evil." There are people in this world who seem to spend a great part of their lives in finding fault. Are you one of that sort? On the other hand, may the Lord be praised, there are those who always seem to be looking for the bright side of things, and who seem to be seeing the good traits instead of the bad in almost every one they meet. Mother was one of the latter sort. Bless her memory! That same old mother used to tell us children that we should "love the sinner" while we hated the sin. When Christ or the Christian spirit finds a dwelling-place in our hearts there will be no room for what we call revenge, no room for anger, no room for vexation. While I talk of it, and while I think of it, it seems so far above the life I am living that I am afraid I shall never come quite up to that standard, but constantly waver and drop back.

In closing I wish to make another extract from the *Sunday School Times*. It is a striking figure of the way in which divine love, or God's love, takes hold of sinful humanity and lifts it up into the sunlight of truth and righteousness.

LIFTING THE SUNKEN.

"I came not to call the righteous, but sinners." A very striking method is now successfully employed for raising the cargoes of sunken vessels. A huge electro-magnet, operated from the deck of the vessel, is lowered to the submerged cargo; and if it be of a character subject to the influence of magnetism it is attracted and lifted by this power, and thus easily saved. There is a power from on high which came to seek and save that which was lost. Down in the murky depths of the waters of sin this magnet of love draws to itself sinful souls, and lifts them by its power to the bright sunlight and pure air above.

HIGH-PRESSURE GARDENING

A. I. ROOT

A NEW DISCOVERY.

We are still having them in our Florida home, but they are not all of them connected with either ducks or chickens. What I am going to speak of now comes nearer under the head Market Gardening, or, if you choose, High-pressure Gardening. A few days ago a neighbor brought over a new dish to us, which she said was made from "weeds" that grew on their place. After we had tasted it she explained that it was pokeweed, the new tender shoots being used, some-

thing like asparagus. It was one of my "happy surprises" to find that this same pokeweed, sometimes called poison, is really a delicious vegetable—much better than any of the "greens" that grow in the garden, not even excepting spinach. It comes up everywhere around here, especially where there is a piece of waste ground, making a wonderful growth in a short time. Mrs. Root has suggested that it would pay to cultivate it; and, from what experience we have had so far, I have no doubt of it. This is

another instance where a rank neglected weed is found to be a valuable vegetable; and I can distinctly remember the time when the tomato was thought unfit for food. Some people called it poison; and on looking up pokeweed in the dictionary I found, before the definition, a statement of its being sometimes considered poison.

Now, the other discovery is that it doesn't pay to fuss with old lamp-burners. In the poultry journals we are often told that it is advisable to boil them out in salsoda and water. Well, Mrs. Root had been spending a good deal of time in cleaning lamp chimneys, and had several times suggested that perhaps our oil was poor. But when we threw away the old lamp-burner and bought a new one that cost only ten cents we were agreeably surprised to find not only a much better light, but all of our troubles with cleaning lamp chimneys had disappeared, or pretty much all of them. Don't fuss with old burners. Of course, we have electricity in our home; but it is not put on until four o'clock P.M., and is turned off at twelve at night. If you get up after midnight or early in the morning you have to use a lamp. In fact, the only time I can use this dictaphone is after four in the afternoon or before midnight.

BUCKWHEAT IN THE FLORIDA SAND, ETC.

Some things will grow here in this Florida soil, while others will not. People from the North have many times been disappointed when they came to make garden and grow stuff down here. A short time ago our neighbor, Mr. Stanton, suggested that buckwheat takes kindly to the Florida soil. I sent for some samples from our home, and we were very agreeably surprised to see the buckwheat come up very quickly without any fertilizer of any account. It is now covered with bloom. I do not know that it would pay to raise buckwheat here for grain—probably not for seed; but chickens and ducks eat it with great avidity, and do their own harvesting and thrashing.

Another thing that seems to flourish in our Florida soil is the soy or soja bean. Chickens and ducks eat these almost the same as they eat green lettuce. Wild rabbits also have discovered their nourishing properties.

Rabbits in our neighborhood seem to be quite a pest. They can be fenced off with a two-foot poultry netting. The netting needs to be as small as inch mesh, however, for the young rabbits have a fashion of getting through the two-inch mesh with great facility. The past winter we have had no frost to do any damage worth mentioning, except that our sweet-potato vines were killed down and the beans and corn nipped, but started up again. Notwithstanding, I have had a very good crop of Red Bliss or Triumph potatoes, and they grew and matured in a surprisingly short space of time.

Irish potatoes have been all winter from fifty to sixty cents a peck. Our neighbor to the north has a beautiful lot of potatoes—

about half an acre in extent—that seemed to be so little affected by the Florida hot weather that I asked him what fertilizer and how much he used for growing such luxuriant vines that stood up and kept their color so handsomely. The reply was that he not only used a potato fertilizer pretty liberally (toward a ton to the acre), but he also put on a pretty good dressing of stable manure from the livery stable, paying three dollars per load for it, delivered on the ground. Some of our friends in the North would think this pretty extravagant manuring; but when you come to realize that he will probably get more than two dollars per bushel for his crop, it is not such a very bad investment after all. Our neighbor, Mr. Rood, is still making "big money" from celery and strawberries. They have had 40 cts. a quart during a great part of the winter for their berries. They are now down, however, to 25 cts. People are buying them quite liberally, and almost every day you see people going along with their hands full of baskets of strawberries for which they have paid 25 or 30 cts. a quart.

There has been considerable said about the amount of fertilizer required to grow any thing here in Florida. Neighbor Rood probably uses it as liberally as any one. On some of his big crops he has probably used two or even three tons of fertilizer to the acre that cost something like forty dollars a ton. Below I enclose a clipping from the *Manatee River Journal* for March 21:

Mr. E. B. Rood cut celery this week which will average easily eight hundred crates to the acre. At the present f. o. b. selling prices the net cash yield of this crop will be about \$2200 per acre.

Perhaps not all celery-growers have done as well as this; in fact, only a few of them, I suppose. Yet as a rule they have been doing unusually well during the past winter because of the high prices. I might mention that one car of Mr. Rood's celery went to Omaha; and another, which went off just a few days ago, went to some place in Canada. I don't know why it is that people pay such big prices for Florida celery unless it is because it has been found beneficial to the health. Celery is to the human family something like what lettuce is for ducks and chickens, especially in the winter time. Mr. Rood not only uses heavy quantities of fertilizer, but he has his ground thoroughly underdrained to take away all excess of moisture. On the other hand he has an artesian well to furnish water, through these same tiles, whenever there is a drouth.

POTATOES IN YOUR BACK YARD; A SHORT CUT FROM "PRODUCER TO CONSUMER."

I fear our department of High-pressure Gardening has been rather neglected; but right now (as soon as your eye catches these words) is just the time to wake up. I see potatoes are quoted in the Cleveland papers at \$1.50 per bushel, and old potatoes at that. New ones from Florida are \$2.00 or more; and you who buy by the peck or half-peck

are paying 50 or 60 cts. per peck; and, judging from last year, they will be 75 cts. or a *dollar* through May and June, and perhaps July. Philo has started thousands in growing their own eggs in the back yard, and the boys of America are doing wonderful things in waking up their "daddies" by growing more and better corn on an acre than the world ever heard of before.* Now, with the stimulus of high prices let us see how soon we can have some new potatoes in this same "back yard," and let us also see how many bushels can be grown on a single square rod of ground. The great world does not even yet know of the possibilities in potato-growing. Here in our Florida garden we grew "great beauties" of the Red Triumph, I think in about 50 days. We pulled them out of the hills as needed to go with our green peas, and the potatoes kept right on growing. To get real early potatoes you want to plant *whole* ones of pretty good size,† one in a hill. Have the soil very rich, and break the crust after every rain. Before you plant, have the ground *very thoroughly* pulverized a foot deep. Old well-rotted barnyard manure worked liberally is the best fertilizer I know of; but where commercial fertilizers are used they must be used intelligently. As soon as I reach my Ohio home (probably about April 20th) I expect to show the Roots and Rootlets how to grow their own potatoes. I forgot to say your ground must be well drained; and if it was ridged away up during the winter, you will be far ahead; then if a dry spell should happen to come you want some way to irrigate intelligently. The "high cost of living" and other obstacles before us is simply God's plan of teaching his beloved children important truths and lessons. Not only our prosperity but our *happiness* depends on our being bright, and ready to help ourselves, and in making "short cuts" from "producer to consumer." Now, when you have got an *ideal* little potato patch, write to "Uncle Amos" and he *may* call round to see it.

EARLY POTATOES—IMPORTANCE OF HUMUS.

When we reached our Florida home last November our garden was a great mass of

*The executive committee of the Boys' and Girls' Corn Club of Harrison Co., W. Va., recently perfected arrangements for the show at Clarksburg this fall. Contestants for the production prize on half-acre plots may use any seed corn they desire; but they are not eligible for any of the other prizes. All other contestants must use seed corn sent out from the experiment station at Morgantown or some of their own corn entered in the show last year. Handsome prizes of money and of merchandise will be given. Last year 15 counties had corn clubs and corn shows; 1800 to 2000 boys and girls belonged to these clubs, and raised by scientific methods enough fine seed corn to furnish the State for the next few years. This year the university hopes to extend this work to 40 or 50 of the 55 counties of the State. The county superintendents of schools are placed in charge of each county, and they are taking up the work enthusiastically. The university furnishes free of cost the seed corn and instructions, and sends an expert to judge the corn.

†Of course this will cost something for seed, but I think it will pay for a few for extra early.

weeds, mostly southern grasses. I said to Wesley, "I suppose it won't be possible to spade all this trash under?" "Mr. Root, I can turn it all under if you say so; but it will be some work."

I replied, "All right, Wesley, turn it all under out of sight."

He first cut it off level with the ground with a *sharp hoe*. Then he spaded a deep furrow and tramped the trash down and covered it with the sandy soil, and left my garden looking level and smooth. Now, many Florida people make a big bonfire of this trash from the garden; but our Florida experiment station has recently stated that trash and weeds turned under and rotted as above is worth about *nine times* as much as the ashes when the stuff is burned. But this is not all. Potatoes seem to delight in finding a mass of rotting vegetable matter in which to grow and expand handsome shapely tubers; and the beautiful Triumphs I have spoken of were found right in this mass of rotten hay, leaves, etc. Much has been said and written about "growing potatoes under straw;" but unless you have an abundance of rain it will be a failure besides being a deal of work. The better way is to put the tubers in wet or rotten straw, and cover them with rich soil. Well-rotted stable manure, where lots of bedding was used, is better still; and, in fact, any kind of decaying vegetable matter to furnish humus is the secret in getting large crops of nice potatoes, and getting them quickly. When wheat bran did not cost so much, some astonishing results were secured by putting bran right over the seed potatoes before they were covered. If you can get seed sprouted in the sunlight, as described in the potato book, you will be very much ahead in getting new potatoes quickly.

Now "get busy," all of you, so as to head off the "middleman" when potatoes are a *dollar a peck*. I see by the *Plain Dealer* of April 6 that old potatoes are already \$1.75 per bushel. See below:

CHICAGO, April 3.—Potatoes to-day were selling at \$1.75 a bushel, wholesale, the highest price recorded in recent years. This is contrasted with a price of 50 cents a bushel a year ago.

Impassable roads, inadequate transportation facilities, inability to get at potatoes buried last fall, and urgent shipping demand, are given as reasons by merchants for the high prices.

Housewives to-day were compelled to pay 50 cts. a peck.

THE EARLY JOE APPLE.

Although there have been several inquiries in regard to this beautiful and delicious apple, I have been disappointed since my return from Florida to find only one response to the offer of a free advertisement. It should have been published in GLEANINGS some time ago, as you will notice.

Joseph H. Black Son & Co., of Hightstown, N. J., have the Early Joe apple-trees for sale. We have them here probably 75 years old, and they bore some last season.

Philipsburg, Pa., Feb. 13.

FRANK WARING.

Now is there another nurseryman who has it for sale?

HONEY PROSPECTS.

A GREAT abundance of fruit bloom and beautiful weather is being reported from all over the United States. In many localities the prospects from clover are excellent; but many say there is a great lack of bees, owing to the severe winter losses.

SAMPLES OF BROOD FOR EXAMINATION NOT TO BE SENT TO MEDINA.

We must again remind our readers that we prefer not to examine suspicious brood here at this office. We formerly did this, but now that bacteriological examinations are made free of charge under the supervision of Dr. E. F. Phillips, of the Bureau of Entomology, Washington, we forward all samples which we receive direct to him.

PERFECTLY POLLINATED BLOSSOMS MORE RESISTANT TO FROSTS.

In the *Country Gentleman* for March 23, 1912, p. 13, is a most able article on the value of bees to the fruit-grower. The old idea of bees stinging grapes, etc., is scouted, and the true value of the bee clearly shown. The writer of this article is well informed, as is shown by the following extract:

Bees are absolutely necessary to the farmer and fruit-raiser. Indeed, fruit-raising is chiefly dependent for its very existence upon bees. Of the many varieties of bees, the common honey-bee is the most valuable. Without it the orchardist would be in a sad plight indeed. Although the wind will pollinize some varieties of fruit, Nature's chief aids in her great work of producing more and better fruit are the honey-gatherers. They pollinize the individual blossoms; and as they fly from one tree to another they also accomplish the cross-fertilization so necessary to the raising of good fruit. Their pollen-baskets are filled at one tree, and part of their load is left at the next. For this reason the fruit-raiser should keep bees himself or else encourage his neighbors to do so. If he can possibly manage it, however, he should have his own bees. If he does not wish to keep bees he can doubtless arrange with a near-by beekeeper to have some hives placed in his orchard in early spring. This sort of arrangement is reported from California, both beekeeper and fruit raiser being well satisfied.

Fruit failures are often caused by wet or cold weather. At such times the bees work only in the home orchard or in the immediate neighborhood. A few sunny hours will give them a chance to pollinize the bloom near the hives; and as a rule, during such weather, they will give their whole attention to the home orchard. Since fruit bloom that is "set" will stand a lower degree of frost without damage than the unpollinized bloom, prompt pollinization may easily be the means of

saving a crop of fruit from destruction by frost. Bees are to the fruit-grower, therefore, a sort of frost insurance.

DO BLACK BEES WINTER BETTER THAN THE YELLOW RACES?

ONE of our subscribers, referring to the wintering of bees in his locality, writes that the blacks wintered fairly well, while the yellow colonies were either weak or died out altogether. It will be remembered how, years ago, we used to have to buy up colonies of black bees to make up for losses of Italians. We have never believed there was any very great difference between the black and yellow bees in the matter of wintering. In most cases which we have traced down, we have found that the bees that have wintered well have had some favorable conditions that the bees which died did not have.

One of the most favorable conditions for wintering bees is a spot that is sheltered from the fierce wintry blasts. Box hives, usually under a shed, with its back to the west or prevailing winds, often winter quite well, when Italian bees in doubled-walled hives out in the open die. Perhaps there is a lesson here in combining shelter from the winds and double-walled hives. We are coming to believe more and more that we do not attach enough importance to wind-breaks, whatever we may say about the value of double walls and porous packing. Let's have both in the future.

WHY CLOVER YIELDS SOME SEASONS AND NOT OTHERS; THE QUESTION OF LIMING.

On page 97, Feb. 15, the editor calls attention to the lessened yield of clover, and attributes it to the exhaustion of lime in the soil. I may be a little dull, but I don't see why we should now and then get an abundance of honey from clover when no lime has been added to the soil.

Middlebury, Vt.

J. E. CRANE.

As we explained in our editorials on this subject, there are many localities where there is no deficiency of lime. When clover fails to yield, the failure, in such cases, is due to other causes, such as winter-killing or drouth. When conditions are just right for a clover flow, a deficiency in lime will not necessarily prevent a yield of nectar; but when they are from poor to fair, a lack of lime means a total failure of clover honey.

Now, then, if the right amount of lime is put on poor soils at the right time, and in the proper way, they may yield clover nectar even under poor or fair conditions. Do we make the matter clear? In any event, do not get the notion *all* soils everywhere need lime. But there is a tendency toward a lime deficiency everywhere; and in many localities the lime has gone out so much that the land has become clover-sick. There is, in fact, no "sickness" about it, but a want of one element—lime. Clover, like animals, must have a balanced ration. Chickens, for example, must have green food and grain in order to lay in the spring. They must, in fact, have a variety. This item by Mr. Crane was written for Siftings; but as it required a more elaborate answer than could be made in that department we have placed it in the editorial columns.

LESS FRUIT ON ACCOUNT OF LACK OF PROPER POLLINATION OF THE BLOSSOMS.

The severe losses that took place last winter will probably mean a considerable reduction in the amount of fruit produced, by reason of the fact that there will not be enough bees to pollinate the fruit blossoms properly in many localities. The fruit-growers are feeling this very keenly, and are making strenuous efforts to get bees from somewhere.

A large number have asked where they can get bees to make up for winter losses. Only a few have responded saying that they had bees for sale. Among the former is W. J. Manley, of Sandusky, Mich., one of the most extensive honey-producers in this country. Parties who have agreed to furnish him a carload of bees are now unable to do so, owing to the severe winter losses. You will find elsewhere that he has in the Wants and Exchange department an advertisement for bees. Albert J. Hann, of Pittstown, N. J., is another party who would like to get in touch with some one who has bees for sale.

We have a carload of bees on the way from Florida, that we expect before this journal goes to press. We shall probably send out an order for another carload. We have been hunting right and left for bees in the North, but have secured only a few scattered lots. Practically every one who has any bees is mighty glad of what he has.

David Keene, of Blackbird, Del., has twelve of fifteen colonies of hybrids in eight-frame hives that he will sell at \$3.00 at his postoffice. If any one has any bees for sale now is the time to advertise them.

THE NEW POSTAL RULING CONCERNING THE MAILING OF QUEEN BEES.

On March 23 the Postoffice Department amended paragraph 7, section 496, general order 6158, to read as follows:

"Queen bees and their attendant bees, when accompanied by a certificate from a State or Government inspector that they have been inspected and found free of dis-

ease," may be transmitted in the mails. The literal enforcement of this order would make it almost impossible to ship any queen bees, practically ruining the queen business, and causing a serious handicap to bee culture in general. When we received notice of this amended order from the Postmaster-General we had on hand something like a hundred queens ready to go out. While our apiaries had been inspected by our State foul-brood inspector last year, and found free of disease, yet this particular lot of queen bees and their attendants, which we were proposing to send out, had not been inspected. Obviously it would be impracticable for any State or Government inspector to see every queen bee and her attendants before they were sent out; and, besides, no examination of the queen bees and their attendants would show the presence of any contagious disease such as American or European foul brood in the hive from which they came. An examination of the brood is what determines the condition in this respect. The order, therefore, was clearly unworkable. Evidently some blunder had been made. We immediately took the matter up with Dr. E. F. Phillips, of the Bureau of Entomology, and our manager, Mr. Selser, of our Philadelphia office. The result was, a letter from the Department of Agriculture, signed by Secretary Wilson, was sent over to the Postoffice Department, recommending a further amendment reading as follows:

Queen bees and their attendant bees when accompanied by a copy of a certificate of the current year from a State or Government apiary inspector, to the effect that the apiary from which said queen bees are shipped is free from disease, or by a copy of a statement by the beekeeper made before a notary public or other officer having a seal that the honey used in making the candy used in the queen-mailing cage has been diluted, and boiled in a closed vessel.

This was accepted by the Postoffice Department, and duly signed by Postmaster-General Hitchcock, May 3. It will be observed that this amended form is workable, and at the same time still makes it possible for a queen-breeder who can not secure the services of a State or Government inspector to send out queen bees, providing he makes oath to the effect that the honey he uses in the candy has been properly diluted, and boiled in a closed vessel. The order of March 23 practically prohibited the mailing of any queen bees, and had it not been for the latter half of the newly amended paragraph 7, queen-breeders so situated that they could not secure the services of a State or Government inspector would be compelled to go out of business. The new order, of May 3, is a step in advance. It will not handicap queen-breeders nor beekeeping in general as did the order of March 23. It will prevent the spread of bee diseases through honey from infected hives that might be used in making the queen-cage candy.

When we prepared the editorial that was published on page 222, advising all queen-breeders to boil all the honey they use in

making queen-cage candy, we were not aware of any new ruling contemplated by the Postoffice Department. While most of the principal queen-breeders subscribed to our recommendation, there were some who did not. These latter have since sent in their names agreeing to boil the honey. In the mean time the recent order of the Postoffice Department makes it obligatory on all breeders—at least so far as it relates to queen bees sent through the mails.

As it is not practical to send single queens by express, we anticipate that the new ruling of the Postoffice Department is going to prove of great value to the industry of beekeeping in the United States. The Bureau of Entomology, and particularly Dr. E. F. Phillips, is to be commended for its promptness in securing a recommendation signed by Secretary Wilson for a workable ruling. Had the amended ruling not followed as soon as it did, thousands of queens would have been lost, and a great damage would have been done to the industry at large. All is well that ends well, only in this case we are better off than we were.

THE AMERICAN BEE JOURNAL AND THE BEE-KEEPERS' REVIEW CHANGE HANDS.

ABOUT a month ago we were informed that the *American Bee Journal*, owned by Geo. W. York since 1886, had been sold to C. P. Dadant & Sons, of Hamilton, Ill. That journal will be published hereafter at Hamilton, and all remittances and communications to the paper should be sent to the Dadants as above. Further announcements, doubtless, will be made in the *American Bee Journal*. We understand that Mr. York has gone into other business, and that Mr. C. P. Dadant, who has been a frequent contributor to "the Old Reliable," will be the new editor.

Mr. Dadant is one of the best-known beekeepers in the world. His crops of honey have gone up into the thousands of pounds. At one time the Dadants owned and operated some seven or eight out-apiaries. Both the senior, the late Charles Dadant, and in later years his son, C. P. Dadant, have been recognized as authorities on bees, not only in America, but particularly in Europe. Indeed, the Dadant system of management and the Dadant hive are used very largely by the most progressive beekeepers of Europe. Mr. C. P. Dadant, therefore, comes into the editorial field as one peculiarly well equipped for the work. The Dadants have always been recognized as thoroughly conscientious in all their dealings, and it is not necessary to say they have been successful in their business. Any one who knows any thing about the Dadants knows that their product, comb foundation, has always been of the very highest grade. For many years they have advertised, and stood by their guarantee, that every inch of their foundation is equal to the samples they send out, and the best they can make. It is, therefore, with peculiar pleasure that GLEANINGS

extends the right hand of fellowship to the new proprietors of the *American Bee Journal*.

Some months ago we announced that Mr. E. B. Tyrrell, of Detroit, Secretary of the National Beekeepers' Association, had acquired the *Bee-keepers' Review* from the wife of its former editor and proprietor, Mr. W. Z. Hutchinson. Mr. Tyrrell took hold of the paper with zeal and enthusiasm. He has done what many another man could not have done with ten times his experience; and that is, he has maintained the old subscription list of the *Bee-keepers' Review*, which everybody said would die a natural death when its old editor and founder passed away from the scenes of this earth. As we have before said in these columns, Mr. Hutchinson was a most remarkable man. He was one of the best editorial bee writers this country has ever known. He had an attractive, clear, and concise style. His personality was unique. When such a man died, naturally every one supposed that no one could be found to take his place.

But it appears that in his capacity as editor of the *Bee-keepers' Review* and Secretary of the National Beekeepers' Association Mr. Tyrrell has really been compelled to do many things double, simply because they applied to different kinds of business. Then came the question of separating the office work of the National from his own private work on the *Review*. Then there was another factor to be considered, and that was, there was a demand for an official organ that could represent the organized bodies of beekeepers located in the various States. To make a long story short, it was finally decided to sell the *Review* to the National. Announcements are now out stating that the actual transfer has taken place, and the *Review* is now the property of the National, to be edited by its present Secretary, Mr. Tyrrell. Just how far the policies of the *Review* will be changed, of course remains to be seen.

In Europe there are several beekeepers' societies that have their own official organs, and naturally enough the question arises, "Why should not the beekeepers of this country, in their organized capacity, have an organ of their own?" The question has been answered now, and what its success will be is yet to be determined. Of course, it means that the National will be responsible for its finances, and it may be that its directors will have to dig down into their pockets to tide it over some tight places. There seems to be entire harmony of action on the part of the directors toward Mr. Tyrrell, the Secretary, and we see no reason why, with good management and co-operation, the new deal should not be successful.

Mr. Tyrrell is a young man of sterling qualities. The merry twinkle of his eyes will win friends toward the new project everywhere. It is a pleasure to know him. If any one can put an official organ on a paying basis he can. Success to you, Bro. Tyrrell, and your directors.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

JUST BEEN OUT looking at the white clover, April 29. Looks rather scarce.

AS A SOIL-IMPROVER, sweet clover is not half appreciated. At the Ohio Experiment Station sweet clover land yielded 45 per cent more corn than similar land not in sweet clover the previous year.

THE SUGARED HONEY in your brood-combs will be wasted by the bees, W. P. F. Spray them with water, preferably hot; and as often as the bees lick them dry, spray again. [Right you are, doctor.—ED.]

IF NECTAR CONTAIN 75 per cent or more of water, and honey contains 25 per cent or less of water, then for every pound of honey stored, two pounds or more of water must be gotten rid of. [This is about right.—ED.]

"TO PAINT hives is not advisable, because painted hives favor dampness inside. At the most, paint only the front." That's an answer in the question-box of *Bienen-Vater*, p. 350. Doolittle and I would feel quite at home over there.

"SWEET CLOVER" is the title of a new government bulletin. It's fine. Also it's free. Send to your congressman or to the Secretary of Agriculture, Washington, D. C., for Farmers' Bulletin 485. Get your farmer neighbor to send for it.

J. SUPER REPORTS, *Schweiz. Bztg.*, p. 47, that he had a colony with many bee-lice. In the evening he shoved a piece of camphor under the bottom-bars upon a paste-board. Next morning he drew out the paste-board and found upon it about 200 dead lice, with no harm to queen or bees.

THE DISCUSSION as to bees throwing out excess of water while on the wing has been taken up in European journals. There is a general agreement with the views of Messrs. Root and Hand. Only a very few think the water is, perhaps, thrown out by the mouth. [We are glad to know that our views have been confirmed. European writers on bees are usually careful observers.—ED.]

HOW MANY FIELD BEES in an average colony? Pf. Burghardt, *Leipz. Bztg.*, 24, says 13,300. Coel. Schachinger, same journal, p. 47, says 8000. It's of some consequence to have the matter settled. Who will help settle it? And, by the way, what is an average colony? [We should say the answer to this question depends on the locality, the kind of hive, and the methods used. A hundred different beekeepers, variously situated, might, therefore, give a hundred different answers.—ED.]

IS THERE NOT some mistake about Father Langstroth living at Hamilton, O., as mentioned p. 232? In 1858 he moved to Oxford,

O., where he did, for that time, an immense business in Italian queens. From there he moved to Dayton in 1887, where he died Oct. 6, 1895, falling dead in the pulpit after preaching a sermon. One of the things I have to be proud of is that in 1873 he made a call on me while I was living in Cincinnati. [We know that he lived at the places you mentioned, and he probably lived at Hamilton. Who can tell us?—ED.]

HERR BOHN, editor *Maerkischen Bztg.*, has for years followed the Swiss method of queen-rearing, and sounds a warning against it. It involves the American plan of starting cells, which he thinks sufficiently against nature to result in deterioration in the course of time. Any way, my plan of letting the bees start cells on their own combs is not open to this possible objection, and I can raise just as good queens, even if I can not raise so many thousands—*Bienen-Vater*, 322. [A great deal depends on who starts the cells. There is a right way and a wrong one. Some beekeepers can never make a success of any plan. A few do.—ED.]

PASTOR FLEISCHMANN, *Ill. Monatsblätter*, 15, quotes the editor of *GLEANINGS* as estimating the annual consumption of a colony at 200 to 250 lbs., and says "neither estimate suits our conditions. With 30 lbs. of winter stores a colony comes through very well till the next harvest; and so large a consumption in summer is incredible, and colonies on scales show that it is impossible." I'll swear by the editor of *GLEANINGS*; but it might be a good idea to have some figures to settle the question. [We wonder if Pastor Fleischmann is taking into account the immense amount of stores it takes to rear brood. While 30 lbs. of winter stores will carry a colony through till the following harvest, yet, if it could not gather any more stores from the time bees are able to fly until the harvest, it would use up its 30 lbs. in short order if brood-rearing were started, long ere the beginning of the honey-flow. It would seem to us that Pastor Fleischmann is not taking into account the fact that in most localities, and probably in his own, bees in the spring and early summer are constantly gathering some stores—nearly enough to keep up brood-rearing, so that the 30 lbs. given in the fall will supplement the amount that they gather from week to week to carry them through till the harvest is on. Our estimate of 200 to 250 lbs. took into account not only the amount the bees had in the fall to go into winter quarters with, but the amount that they gather during the following spring and summer that is absorbed in brood-rearing. These estimates have been confirmed by a number of beekeepers on this side of the great water.—ED.]

SIFTINGS

J. E. CRANE, Middlebury, Vt.

The Department of Agriculture at Washington has issued a bulletin on sweet clover. Let us see that it is well distributed among the farmers of the country.

I was not aware that the annual loss is as large in California as Mr. Chadwick states on page 101, Feb. 15. More and more I am led to believe that all the good things are not in one place.

If beginners in beekeeping who intend to do much business will cut out the editor's footnote on page 98, Feb. 15, and paste it up where they can always see it, and follow its advice in marketing honey, it will prove a perennial source of profit.

Those illustrations of J. B. Case's nucleus frame and top-bar, page 117, Feb. 15, are true to the real thing, and the best I have ever seen for their purpose. Mr. Case is a modest man, but is doing some good work along the line of queen-rearing.

That is what I call a capital idea, giving a whole number of GLEANINGS to bees and fruit, or largely so, as is done in the number for March 15, and then on top of that an offer to send free a copy to those fruit-growers whose names beekeepers may send to the office.

In talking with Mr. Geo. Demuth, of the Department of Agriculture, Washington, he said that the weather reports of the Weather Bureau might be of considerable value in fortelling the weather to those taking bees out of winter quarters in the cellar. This is both a new and a good idea.

I believe friend Byer is right, page 70, Feb. 1, in advising the use of a wax-press. If one has much wax to extract, it will soon pay for itself, although Mr. Poppleton, of Florida, with whom I have been stopping for some time, renders all his wax by means of the sun's rays. But the sun is about as hot here in January as in the North in July.

From conversations that I have held recently with Dr. Phillips and Editors Root and Tyrrell, it seems certain that not more than one bee-keeper in six or eight takes a bee journal of any kind. If we are to fight bee diseases successfully, shall we not make a strenuous campaign against the appalling ignorance of the beekeepers of the land as a strong force in controlling foul brood by increasing the circulation of such publications as are devoted to beekeeping.

Dr. Miller quotes, page 36, from *Deutsche Imker*, the remarkable fact that "a mixture of two honeys is darker than either kind separate." Funny! We have for years been mixing light honey with dark to improve the color of the dark honey, and thought it did. It must be that we are color-blind not to have seen that it made matters worse.

I was with Mr. O. O. Poppleton when he read that item on page 99, Feb. 15, regarding windbreaks. He thinks that, instead of a single item, the subject is of sufficient importance for a full article; for in wintering bees in the North, shelter from winds is of the utmost importance. We all know how much more we suffer from cold when working or riding in the wind than in a quiet atmosphere.

Dr. Miller, page 69, Feb. 1, says that he doesn't know why moths prefer old dark brood-combs rather than clean combs in sections. Let me suggest that most insects that lay eggs seem to know instinctively the food best adapted for nourishing their young, and doubtless the moths that lay eggs know that old dark brood combs containing more or less nitrogenous matter are far better food for their young than white section combs, for the larvæ of moths can no more be reared without nitrogenous food than the larvæ of bees.

Mr. Wm. T. Fritz, of Canastota, N. Y., writes to know if the Davis hive is like the Manum. I may say it is not, and that neither of them has any special point of interest for bee-keepers at the present time. He also desires to know if sections should be graded so as to make all in a case weigh the same. To this I would say it is not our custom to do so, for then some cases of heavy sections would weigh 25 or 26 pounds to 24 sections, while other cases would not weigh over 21 or 22 lbs. per case. Better make the cases average 23 pounds if possible.

A little boy wrote a composition on pins. He said that they are very useful. Girls use them to pin up their clothes, and they save a great many lives. The teacher inquired how they saved so many lives. His reply was, "By not swallowing them." Stopping for some time in a section of Florida where a large number of rattlesnakes have been killed, and where several persons have died as a result of being poisoned by rattlesnakes, I inquired as to the value of whisky, that all my life I had heard praised as a sure antidote for snake poison. I was told that its value for this purpose consisted in not swallowing it.

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas

A GOOD HIVE-NUMBER WANTED.

Hive-numbers are good things, especially if more than one person looks after the bees. It often happens that something has to be done to a certain colony on the next trip to the apiary; and while the person there before knows the location of that particular hive, it is not an easy matter to tell to a certainty to others just which one it is unless they also are well acquainted with the location of all the hives. But how easy it is to say "No. 34," or any other, for that matter! and how easy it is to find that number on a hive, although we may never have been there before!

But here is a question: What are such numbers really worth? and what ought a good, durable, substantial hive number that can be put in place in a jiffy, changed from one hive to another in the same length of time, and one that will last a lifetime, cost? At the present time there is no suitable hive number on the market, that we know of; and if there were one, how much could the bee-keeper afford to pay for it? We have been thinking about numbering all our hives with a good hive-number; and as there are a thousand or more hives to number, the question above naturally crops out. Will some of those who know, therefore, tell us all about it? It will be highly appreciated at this time.

THE TEXAS OUTLOOK.

Not for many years have the prospects for a good crop been brighter than this spring. Although the winter was the longest and the most unfavorable for perhaps twenty years, according to many authorities who have kept bees and have watched the weather from year to year, the outlook is better than was really expected by many of us. There has been an abundance of rain since last fall, in most localities. As a consequence all kinds of vegetation are in great profusion and of luxuriant growth. This is indicative of a great mass of bloom yielding honey much more abundantly than even under average conditions. Judging from this, then, other conditions being favorable, the honey crop will turn out to be one of the best we have had for several years.

The bees, as a rule, are in good condition in spite of the long-drawn-out winter. While the unfavorable weather conditions were, perhaps, not felt so much in Southwestern Texas, reports from our correspondents are to the effect that the bees suffered considerably in the northern localities of the State. There were very few days favorable enough so that bees could work on the bloom that did make an early appearance; and many of the otherwise early flowers were delayed materially on account of the continued cool wet weather. In some apiaries this was so marked that the bees, which were rearing

brood at a rapid rate, and consuming their stores, had to be fed to prevent starvation. This was a critical condition in beekeeping, since the shortness of the stores at this time has a detrimental effect upon the progress of the colonies, in that much brood is subjected to starvation, and destruction by the bees themselves. Bees short of stores will devour not only large numbers of eggs but young larvae at this stage of discouragement before the beekeeper may discover the actual serious condition prevailing. It is, therefore, of the utmost importance to watch all colonies closely and to supply necessary stores *before* such harm is done instead of waiting until the bees are found actually in a starving condition. To wait so long will require a longer time to become populous for the honey-flows, if, indeed, the colonies regain enough strength to gather surplus honey. The beekeeper who knew how to take care of such conditions properly and promptly is being repaid abundantly for his timely precautions.

Thus we find that the bees are in good or bad condition in various localities according to the ability of their owners to take proper care of them. The shiftless beekeepers with their "gums" are, as a rule, the heaviest losers. It is they who assert positively that the "worms" have killed their bees, when in reality they starved out before the wax-moth larvae got into the beeless combs. The beekeeper here who prepares his colonies in the fall with more honey than they may need for winter will find little opportunity to worry about the bees wintering safely. If it is borne in mind that the bees really need more honey to spring them than to winter them, enough honey will be left to last well into spring. The honey not actually needed will not be lost, but, on the contrary, will result in rousing colonies of bees for the honey flows. This means a larger return in surplus honey—that which makes beekeeping a profitable business. The past winter has aided in teaching this lesson more thoroughly, and it is hoped that it will be heeded in the future.

Nine Virgin Queens Captured from a Colony Caught in the Act of Swarming

One sunny morning I was attracted by the piping of a queen in one of my hives. I went to investigate; and just as soon as I came up it began to swarm. It was a colony that had come from a swarm in the spring. I was surprised to find three young queens with it. I then went through the hive and found the original queen and four more queens hatched, and two more tore the caps off and ran out, so that made nine queens out. I caged them all and put the swarm back, and the colony stopped working. So I let one queen go, and the colony set it again. The colony is now in fine condition. It produced 96 lbs. of honey of good quality last season. You may be sure I made good use of the queens. They are the best I have. Two are ahead of any others in the whole yard.

ALLEN A. STRATFORD.

Kainga Tui, Orinoco, New Zealand.

BEEKEEPING IN CALIFORNIA

P. C. CHADWICK, Redlands, Cal.

All beekeepers in San Bernardino County who will assist in organizing a county club will kindly communicate with me at once.

Thousands of colonies were moved to the orange districts during the dry-weather scare. Nearly all of these will be returned to the sage-fields if they should give promise later of a fair yield.

Orange County is said to have the strongest county club in the State. Ninety-five per cent of the crop of the county is produced by those represented in the membership, which is organized into a splendid working body.

Our county bee inspector, Mr. Herron, openly defies the beekeepers to cause his removal from office. Those who think our foul-brood laws are adequate may have the job. I prefer to use my energy in getting a law that will leave the matter in the hands of beekeepers. *He will go then.*

While passing a white-clover lawn a few days ago I noticed about forty bees industriously working on the bloom. Within a short distance were quantities of orange blossoms fairly dripping with nectar. I offer no explanation, other than to suggest that the bees were "tender feet," just from the East, that didn't know a good thing when they saw it.

WARMER WEATHER NEAR THE COAST MAKES UP FOR THE FOGS.

This morning (April 24) there was a heavy fog-bank visible toward the coast, ten or twelve miles away. This condition is much more prevalent nearer the coast than here in the inland sections, giving us the advantage during the orange flow. This advantage, however, is largely offset by the warmer weather and more even climate under the influence of the ocean, nearer the coast, encouraging earlier breeding, which results in stronger colonies to work on the orange, whenever the weather is suitable.

HATCHING BROOD CAN STAND A LOW TEMPERATURE.

In spreading brood my observation is that it is wise to put sealed combs (hatching preferred) on the outer sides of the brood-nest; for if cold weather should drive them in dangerously close, the sealed brood will stand a lower temperature without injury than young larvae. This was very forcibly impressed on my mind last season when, three days after having transferred a colony, I noticed bees hatching from scraps of brood-combs after having been exposed to a temperature ranging as low as 40 degrees. The loss would be greater if the sealed brood

should perish than if only eggs or larvae; but if there should be danger of that, it would be better not to spread. Spreading is really never safe until one's bees can cover more combs than they have brood.

ORANGE BLOOM WITH SNOW ONLY THREE MILES DISTANT.

On April 12 my bees, three miles back in the foothills, and at an elevation of several hundred feet, were snowed under for a few hours; while in the valley below, oranges were blooming, waiting for the visits of the bees. Such a contrast is rarely equaled in this country. The entire week was very cold; the quantity of stores consumed was alarming; many colonies having an ample supply under ordinary conditions almost reached the starving-point by the end of the week following the storm, as the weather that week was so cloudy that the bees could take very few flights.

AVERAGE YIELD IN CALIFORNIA.

Wesley Foster's estimate, in *American Bee Journal*, of 50 pounds, extracted, per colony, as quoted by Dr. Miller, p. 223, Apr. 15, as being an average for specialists would not apply in California. I think 100 pounds would be a conservative estimate, taking into consideration that some years, outside of the orange and alfalfa districts there is practically a total failure. The average yield per colony, for Orange County, California, in 1884, was 700 lbs. per colony; in 1905 the yield for Southern California was 300 pounds average. These, to be sure, were exceptionally heavy-yielding seasons, but would figure largely in the average.

SAGE FLOW DOUBTFUL.

The rain question is no longer an unsettled factor in reckoning conditions on which the honey crop of 1912 will depend.

A local weather observer reports the storm from April 7 to 15 as being the heaviest for April in 28 years, nearly 4 inches having fallen during that period. This, added to what had previously fallen since March 1, makes 9 inches of late rain. The ground is thoroughly soaked to a good depth. At this writing (April 30) the sage seems still uncertain as to yielding; and after making close observations I can see no great hope of more than a light flow. There will surely not be any great profusion of bloom, for the growth does not indicate such. I may be wrong; but it seems to me that the late rains are forcing it out of its season. The result, I venture, will be little more successful than forcing certain other plants out of season. That there will be some bloom is quite certain; but many of the older bushes will bloom very little, if any; and whatever the yield may be, it will come late.

Conversations with Doolittle

At Borodino, New York

HOW TO ARRANGE SUPERS ON HIVES.

Among my many other books on bee culture I have "A Year's Work in an Out-apiary." I note that you advocate putting on two empty supers at the same time. I never tried that plan. What I want to ask you is this: How would it work to put the sections filled or partly filled with comb for baits in the top super, and none below? Would that not cause the bees to fill the top super first, and thus prevent all travel stain on the lower sections? I know by experience that it pays well to have one bait section in every row of sections.

In order to answer these questions I must "ramble about" to a certain extent. At the outset I wish to say that "A Year's Work in an Out-apiary" was written from an *out-apiary* standpoint. In the home apiary I rarely put two supers on any colony at the same time, unless that colony is a *very strong* one. The reason for this is that I am always on hand to attend to the wants of the bees in the home apiary; and if I had five out-apiaries and the home yard this home yard could have some of my attention at morning and night of the days spent in the out-apiaries, in addition to the whole of the sixth day spent at home. A quarter of a century or more ago we were firm in the conviction that no more super room should be given at one time than the bees could occupy at once. From this conviction, one, two, three, or four of the six boxes holding from six to seven pounds each, that the super of the Langstroth hive accommodated, were put on at first, little doors in the honey-board over the brood-chamber being fixed to close the entrances for each box when these were not on the hive. On scores of hives I put on only one of these seven-pound boxes at the start of the season; when, if this was occupied with bees, one more was added a day or two later, and a little later another, until all six were on. Now, any one will see at a glance that no out-apiary could be worked along this line.

It will also be seen how apiculture has progressed during the time since Mr. Langstroth first put his hive before the apicultural world. No "sections" were known at that time; and the term "baits," when first used with sections, had to be explained to the average beekeeper. With the arrival of sections came opposition, on the ground that a whole super must be put on at once; and to overcome this objection, Mr. Manum, of Vermont, a leading beekeeper of those days, clamped a single row of sections in a very light frame, so that in this way this principle of only a small amount of room at a time could be used with sections the same as had been done with the boxes. These light frames of sections could be put on one at a time till the top of the hive was covered and thus a "bridge" was made that finally spanned the chasm between the one-box-at-a-time theory and the putting on of a whole super of sections covering the whole top of the hive as we do to-day. After a while it was discovered that, by putting in

bait sections, one in each row, such as our questioner mentions, the bees could be coaxed into this whole super sooner than they would occupy one of the light frames, as made by Mr. Manum, without a bait.

The next step was to "stretch" the bees out still further; and so as soon as they were well at work in this first super it was raised, and an empty super of sections put under it. This caused the bees to commence work immediately in this empty super, so that they might not have an empty space between the brood below and their treasure house above. This became known as the "tiering-up plan." But many of us soon found that, unless the season proved to be an extra good one, or one long drawn out, we had from one-half to three-fourths of the sections worked in, unfinished at the end of the season, with only a small portion of our crop in marketable shape; while if we had not tiered up, our marketable product would have been twice as large. From this came the idea of putting the super of empty sections on top of the one the bees were at work in, and then, if more room was needed, the bees would "overflow" into this upper super, and work would go on equally well without danger of three-fourths of the sections being left in an unfinished state. There was also no danger of the "dish being bottom side up" if there should be an unexpected "rain of porridge." The objection to this empty upper super on top was that it allowed the heat of the colony, and especially of that from the bees at work in the first super, to pass up into this empty one above; and from this loss in temperature the bees could not work in the super next to the brood-chamber to as good advantage. But the observing ones found that the "crust bees" were able to keep the heat in the first super, when needed, by clustering in the beeways between the tops of the sections, so as to keep the heat just where they wanted it, so that the temperature of this empty super at the top was very little if any warmer than that of the outside air.

Turning to the main question of this correspondent, if one is at work at the out-apiary, and has a colony so strong that he thinks one super will not be sufficient until he comes again, the two are put on as given in the book. But I hear him asking, "Why not, as I suggest, put the super with the baits at the top?" Because the condition would then be almost if not quite the same as in the tiering-up plan. In other words, these baits would be so far away that they would not draw the bees into the supers at all; or if they did, the bees would commence in both supers at once, so as to have a connection between the bait combs above and the brood combs below, which would materially lessen the prospects for many marketable sections, especially if the season should prove to be a short or poor one.

General Correspondence

HONEY PRODUCED IN DISEASED APIARIES

Breeding from Queens whose Bees are Practically Immune

BY OREL L. HERSHISER

Brood diseases are rampant in many wide areas, and are, in each succeeding season, breaking out in localities heretofore free from disease. The annual increase seems to be in almost geometric ratio. That these diseases will soon overtake every apiarist in the country seems evident from authorized reports, notwithstanding all that official and private inspection and treatment has been able to accomplish in the way of staying their progress. Complete eradication of brood diseases, the country over, seems to be out of the question, and we may as well, and better, turn our attention to what is far more practical and profitable—namely, to becoming disease experts. That is what we must do if we are to continue in the honey-producing business as an occupation.

Much honey has been produced in recent years, in apiaries more or less affected by brood diseases. The percentage of such honey bids fair to increase annually for some indefinite time to come. This, at first thought, is not a pleasing condition to contemplate; but being confronted by that fact, the question for us to consider is, "With brood diseases present in the apiary can we profitably produce a crop of wholesome honey?"

We have been assured, by those qualified to advise, that the germs of brood diseases are in no way injurious to the human being. This is a most important fact. So important is it that, if the reverse were true, beekeeping as an occupation would speedily cease to be. So important is it, therefore, that this one item of knowledge may truly be said to be the cornerstone of the foundation upon which apiculture rests.

In the spring of 1909 European brood disease appeared in one of my apiaries. I could not believe it at first. Spraying of shade trees in Buffalo, within reach of the bees, had been in progress, and poisoning seemed to me a proper explanation for the presence of many dead larvæ in many colonies. However, when the summer was nearly over, an authoritative statement from Dr. Phillips, Washington Government Expert, convinced me that my apiary had been overtaken by the disease. It was too late to treat the bees that year. The disease had obtained a season's start. My first impulse was to destroy the apiary, root and branch. A request to our State agricultural department brought to my aid Messrs. Stevens and Stewart, two of our highly efficient State bee-inspectors. They gave me hope, and better counsel prevented the destruction of the apiary. Four colonies were given the

fall treatment by shaking upon combs of honey brought from another apiary that was not diseased. Fifty-eight colonies in this apiary were packed for winter that fall, several of which were the result of uniting weak diseased colonies. Fifty-four colonies were alive in the spring following, eight of which were weak. The first examination showed all but about half a dozen more or less diseased; and it was thought advisable to treat all that showed it. In my anxiety to get the disease under control as speedily as possible I was a little premature in treating the first eight colonies, which were the weaker ones, and lost four of them, leaving fifty colonies, spring count.

A plan of treatment embodying well-known principles, but varying from set rules in matters of detail, was thought to be sufficient, and, accordingly, all diseased colonies were treated. This included all but about half a dozen colonies of a fixed strain of Italian bees that has never shown the slightest trace of the disease. It may be remarked that, in my experience, confirming the statements of numerous experts in brood diseases, blacks, hybrids, and some strains of otherwise good Italian bees are particularly and possibly peculiarly susceptible to European brood disease, and are apparently predisposed to it. On the other hand, certain strains of Italian bees seem to be almost if not quite immune to it. Be this question of complete immunity of certain strains of Italians as it may, it is my personal experience that five or six colonies of Italians in this apiary never took the disease, which, for all practical requirements in apiculture, constitutes immunity. These Italian colonies were among the strongest and most vigorous in the apiary, and would certainly have carried the disease from the same source as those that were stricken. Other black and hybrid colonies that were equally strong and apparently as vigorous were badly diseased, and only prompt treatment saved them.

A part of the treatment decided upon was the selection of the queen of one of the Italian colonies that had not and did not become affected as the breeder of queens for requeening, and the substituting of queens thus bred for the queens of all colonies that showed the disease.

Being a novice in brood-disease treatment, and having a badly diseased apiary to operate, my crop of honey from it for the season of 1910 was only about 1000 sections and 800 pounds of extracted honey, and an increase to 60 colonies. In the fall not a trace of the disease was to be seen.

The spring of 1911 showed four of the sixty colonies of the fall before dead, and more than the average number of weak ones. Under the influence of settled warm weather they rapidly built up, and to all outward appearance were as healthy as any bees.

During the summer not more than six colonies showed any signs of disease. These were carefully treated, and later in the summer a careful examination showed only one colony diseased, which was a fine Italian, the queen of which I had purchased and introduced in July to a healthy nucleus, which showed that not all Italian bees are resistant to European brood disease.

This apiary was now short of brood combs, for many of them had been melted up the previous season in the process of treating the disease. Wishing to increase the number of these colonies, and to rear queens for my other yards, this apiary, during the season of 1911, was run for comb honey, queen-rearing, and increase. A carefully selected queen was used as a breeder (immunity to disease and good wintering being the main points considered). From this queen as a breeder every colony except eight was supplied with a young queen, the best of those substituted being used in other apiaries. The result of the season's work with this apiary was increase to 107 colonies, the rearing of a goodly number of queens for this and my other apiaries, and the production of 2500 sections of honey, some colonies finishing as high as six 32-section supers, or 192 sections. Only the stronger colonies were run for honey; the weaker ones were used for increase and queen-rearing. Considering the very unfavorable season, the showing of honey was very satisfactory.

The practicability of producing honey in diseased apiaries has *got to be* a foregone conclusion. It is the only thing to do for a goodly number of apiarists. There is no assurance to an absolute certainty that an apiary is without germs of disease, after it has once been infected; but that the honey from such apiary is wholesome for human food seems to be undeniable. There is just one simple direction to be followed in the production of honey from diseased apiaries: Use the queen-excluder on all colonies run for surplus honey, and extract no honey from brood combs. As an adjunct to this direction, let it be stated that the expert apiarist will not long have about his apiaries the brood diseases in noticeable amount, and but one or two seasons will suffice to make them free from disease to all intents and purposes.

There is surely a bright and hopeful side to this question of brood diseases. Has it not been in existence in Europe since the time "when the memory of man runneth not to the contrary"? And are not Europeans about as well supplied with bees as ever? It is not likely that the diseases will be more malignant here than in other countries. The brief manner in which some European writers of the past have referred to it and its treatment impresses us with the idea that it was not considered so very formidable. At any rate it has lost its terrors for me, and I regard it as a blessing in disguise. For me it has resulted in bees that are vastly superior in wintering, in handling, and in honey-gathering qualities.

What at first appeared to be a calamity is turning out to be a money-maker. As a result of it, the apiculturist of the future will be a bee *expert* instead of a mere beekeeper. From these view points it may truly be said, "Blessed be European brood disease."

Kenmore, N. Y.

MORE ABOUT TOBACCO HONEY

BY J. K. GOODRICH

Mr. E. H. Shattuck's article, "The Tobacco Industry in the Connecticut Valley," p. 162, March 15, was of much interest to me—first, because of the thousands of acres grown in this section; and the constantly increasing acreage from year to year. All opposition to tobacco as used by the human race seems to be of no avail, for the use has increased steadily up to the present time, and is still on the increase. But I have wondered how honey made from nectar gathered and stored from tobacco bloom could be wholesome for food. Not until the last few years has the tobacco plant been allowed to flower while in cultivation, so that tobacco honey is of quite recent production. The tobacco plant may be of interest to all beekeepers as being a new source of nectar for honey.

My boyhood days were spent in this locality, and the honey made by my father's bees was a necessary part of my lunch, which was composed of bread and butter and honey.

If I have been rightly informed, in my younger days the first tobacco grown in the town of Granby was a small plot on my father's farm in 1850. One of his employees suggested to him the raising of tobacco more as an experiment than otherwise, and the permission was granted; and from that time to the present the industry has developed to thousands of acres in a comparatively small area of Hartford County alone. New Tariffville, a few miles from Granby, is now the metropolis of the tobacco culture and business; eighty-four acres in one field alone is under canvas, and this field only one of many of the same kind on their plantation to-day.

When on a visit at Granby last summer, Mr. Shattuck very kindly gave me a large sample of tobacco honey for comparison with the honey stored by my bees in the fall season at Waterbury and Middlebury. I found it equal to the fall product gathered in my locality. I might say in passing, that I think there is no danger whatever of contracting the tobacco habit by eating the honey as one would by smoking or chewing the weed.

This plant belongs to the nightshade family (*Solanaceae*), the members of which resemble each other very much—as the potato, tomato, and egg-plant, all of which have a nauseous, disagreeable odor. The honey is dark, with a brownish cast in color, and there is an absence of a rank strong odor, so that it tastes and compares favorably with

the buckwheat product. Mr. Shattuck informed me that no disagreeable results follow the free use of this honey as an article of food by the members of his family.

I wish to say, however, that I was very much inclined to be skeptical as to its being more of what might be called a medical product than a food, like the honey from Brazil, some of which can be used as a medicine only, owing to the poisonous source from which it is gathered. But in this I am happily disappointed, as no bad qualities peculiar to this plant seem to be in the honey when ripened by the bees and placed under favorable surroundings after being removed from the hive. It would seem that this locality in the Connecticut Valley and adjacent territory with its broad acres of tobacco bloom between the buckwheat flow and the fall flowers would be what the buckwheat fields are to the Alexander apiary in New York, where hundreds of colonies are kept in one locality alone, with remarkable success in securing a honey harvest.

Waterbury, Ct., March 29.

PUTTING THE SWARM ON THE OLD STAND WITH THE PARENT COLONY BESIDE IT

BY DR. C. C. MILLER

A Canadian correspondent writes that in 1910 he fell upon a plan of management by which he got from a black colony 400 pounds extracted clover honey. The season was so poor in 1911 that he could not further test the plan, and he wants to know whether I think it will work. He thus describes the plan, which he says is a variation of the put-up plan given in "Fifty Years among the Bees."

A colony in a regular eight-frame Langstroth hive had an extracting-super over a queen-excluder, and this colony swarmed. To the swarm, which we will call A, were given foundation-starters, and it was set in place of B, the mother colony. B was set beside A. The next day I put an excluder over A, on which I put a super of empty extracting-combs, and over this the super from B. When the young queen began to lay in B, I put B in place of A, put an excluder on B; on this excluder a super of empty extracting-combs, and above this the supers that had been on A. A was put on a new stand with its old black queen, which is five years old this year.

The first question that arises is one regarding the safety of the young queen when B is put in place of A, as she is a stranger to all the field bees that enter the hive. But being surrounded by a household of her own bees, she ought to be safe except in a time of scarcity, and she possibly might be safe then.

Instead of a variation of the put-up plan, you have a variation of the excellent plan of putting the swarm on the old stand, the mother colony beside it, and moving the latter to a new stand in a week or so. Your waiting till the young queen lays before moving the old colony to a new stand will, in a large number of cases, result in one or more afterswarms. You don't want that. I don't see what you gain by swapping

hives and brood when you make your last move. You certainly lose two weeks or more of hatching brood, for you take from your honey-hive hatching brood, giving in place of it brood that will not begin to hatch out for something like three weeks. In the long run you will probably do better to stick to the old plan.

This correspondent says further, that, when he gives a ripe cell to a queenless colony, the queen hatches out, but is lost on her wedding-trip; but if the bees rear a queen from the egg there is no such loss. I think it only happened so, and that in general he will find as many losses from wedding-flights in one way as in the other.

BEES MAY KEEP EGGS FROM HATCHING.

A colony swarmed, its young queen was lost, and three weeks from the time the prime swarm issued cells were started with eggs that I am sure were laid by the old queen. How long will fresh eggs keep? Editor Root says fresh eggs keep, if warm, only three days. Not in this locality; they hatch.

I don't know enough about the egg business to speak with authority, but I think there may be no unreconcilable conflict in the case. You say that eggs, if kept warm, will hatch in three days. Surely in the case you cite they were kept warm, and they didn't hatch inside of three weeks. You have good backing in saying they will keep long, for no less an authority than Dzierzon reports eggs being kept by the bees. If I remember correctly it was two or three weeks. But when Editor Root says they keep only three days there is not necessarily any contradiction, for the probability is that he is talking about keeping eggs out of the hive, away from the bees. That's the only way in which we are much concerned about keeping eggs.

Without knowing very much about it I think it quite possible that this is what may be found to be true: That, unlike hen's eggs, bees' eggs will not hatch by heat alone without the presence of bees; that bees have the ability to keep them without hatching for a time, and then hatch them afterward. I don't know whether that's true or not; but I do know that in the fall I find in the hive eggs and sealed brood, but no unsealed brood. The queen continues laying, but the bees stop hatching the eggs—or at least the eggs stop hatching.

Marango, Ill.

GETTING ALONG WITHOUT QUEEN-EXCLUDERS

The Shape of the Brood-nest

BY GEO. SHIBER

On page 715, Dec. 1, 1911, is an article from Mr. Doolittle, on the use of queen-excluders. It is not often that my practical experience is much different from his—in fact, I nearly always agree with what he says on bee management. But I want to take an emphatic exception to what he says on the use of excluders in producing extracted honey.

He says, "And this brood which would easily go into one hive was scattered all through the combs of the two." Now, my queens never lay that way. I never knew of a case. The following is what I can expect from a colony in early spring: As soon as the bees have as many as four combs with brood, the shape of that brood-nest will be in the form of a sphere; and with a good queen, and plenty of pollen and honey coming in, that ball of brood keeps increasing in size until it reaches the outside combs.

We then put on another story of empty combs, and the queen will soon occupy this second story. And this is the way a queen will start in the upper story: First she will lay in the bottom part of the combs in this second story—in several of the central combs. The circle of egg-laying will be maintained, so that the center upper comb will have eggs extend higher than the combs on either side. After a few days this circle of brood will be higher in the second story, but sloping down as it goes toward the outside combs, preserving the spherical shape. I have never seen an exception to this.

About this time clover begins to yield. Another story is added, if needed; but the queen will never go into that unless she is a very exceptional layer. Of course this body is placed on top of the second story that the queen is partly occupying. A queen rarely needs more room than the two lower stories supply. (If this new story were put between the two stories which constitute the brood-nest it would make a bad mess, as then the queen and colony would be thrown completely out of balance, and abnormal consequences would almost surely follow, which would be decidedly unsatisfactory.)

By placing the body containing the empty combs on top it forms the third story. The honey which is coming in at a fair rate is placed first at the top and side of the circle of brood. After this space is occupied the bees will reach up into the third story with honey.

Where do the bees put this first honey in the third story? Never in the upper part of the combs, but in the bottom part first, and then gradually extended upward. (An exception to this, and it also applies to brood, is that, if there is a black comb in the center of the third story, and the rest of the combs are white, never having had brood in them, the black comb will be filled first.)

At this stage the queen and workers will ease up on brood expansion, and contraction will take place. The circle will gradually work down out of the second story into the first; so by the time the harvest is past there will be only a small amount in the second-story combs, and the bees will have filled the cells with honey as the brood has receded.

In view of the above I can not see how a queen could have brood "scattered all through the combs of the two" stories. Normally, bees do not scatter their brood or honey. It is always in a compact shape. At no time between spring and the end of

the basswood flow have I ever known a queen to desert the lower stories to go into the third when it was added. Later they will go up into the second or third story, however, and that time is toward the last of the buckwheat harvest.

If Mr. Doolittle had been talking about the flow from buckwheat I should have agreed, for at this time nine out of ten two-story colonies will have the brood-nest in the top story. If they have no excluder between, I suppose it is because it's warmer, at a time when the nights are cool.

This whole question, however, may be one of location; but my bees, when they have the maximum brood-nest, have it extended to the entrance. I have a pile of excluders in the shop, but I have not used them for several years. I like the present way much better; but one must manage rightly if he wants the best results.

Randolph, N. Y.

SWEET CLOVER IN CENTRAL ALABAMA

BY A. B. BROWN

I am prompted to say a few words in behalf of melilotus, or sweet clover, in view, if possible, of correcting some of the wrong impressions in regard to the plant. I wish to speak of it only as it is looked upon by the planter, the cattleman, and the beekeeper in this part of Alabama, where it grows luxuriantly on the lime soil.

The planter has used sweet clover for years as a land-redeemer, and to keep land (not in cultivation) from washing. Land that is practically worn out, after being seeded to sweet clover for three years, will produce good cotton again. Then, too, when land is poor and washed full of small ditches and gullies, if sweet clover is sown it will hold firm the washing banks, catching the wash of the soil, thereby filling up numerous depressions.

In this section nothing but unhulled seed is used. It is cheaper, and easier to get. For the best results the land is plowed and about two to three pecks of unhulled seed to the acre, sown broadcast. It is not necessary to harrow it in. The rain will wash sufficient soil over the seed. Sometimes a brush is run over the soil for the purpose of covering the seed slightly.

It is a peculiar fact that cattle not raised in the sweet-clover districts do not care for it at first; but they soon learn to like it, and afterward prefer the sweet tender bunches to the other vegetation of the pasture.

The sweet-clover soil (lime soil) of the South is not very extensive, consisting of a narrow strip across Mississippi and Alabama, with some sandy land mixed in, which has no sweet clover. In this section we find that it is a land-builder; excellent to sow in order to keep the soil from washing; fine for the pasture, besides a very good honey-producer, which in its favor have made it a friend and a benefactor.

Hayneville, Ala.

Apiary of Geo. H. Kirkpatrick, Rapid City, Mich., showing method of arranging the hives in pairs. Each hive stands on four cedar stakes.

HOW THE LOCATION AFFECTS THE HONEY-FLOW

Points to be Considered in Laying Out an Apiary

BY GEORGE H. KIRKPATRICK

Much depends upon the location of a beeyard. In the spring of 1909 I had an apiary located on a high altitude, a stretch of country known in this section as the "snow ridge." The bees of this apiary had been removed from the cellar April 14, at which time they were in first-class condition, the clusters occupying seven to eight spaces in ten-frame hives. The nearest water was one mile distant. By June 10 the colonies were reduced by one-half, and I received no surplus. The bees were left for two seasons in this location, and were reduced to a worthless condition. The location was the principal cause of the failure.

Note the difference: At the same date in 1909 I had an apiary 20 miles north, located on a stretch of land lying between Grand Traverse Bay and Torch Lake. The soil is a heavy clay, wet and springy, and there is water in every horse-track in early spring. Soft maples and pussy willow are plentiful. The bees at this apiary had wintered poorly, being reduced to very small colonies while in the cellar. I carried them out April 16; but with a sheltered location, plenty of

water, pollen, and honey-producing plants near by, they bred up to good colonies and gave me a net average of 110 pounds per colony, spring count. The bees in the two apiaries had the same care, each receiving the same number of visits.

LOCATING THE APIARY.

In locating an apiary there are several points to be considered. First is the pasture. We must seek a location where there are hundreds of acres of honey-producing plants. In this locality we seek to find raspberry and milkweed, for on these two plants we depend for our surplus honey. Then for early pollen and nectar we must have maple, elm, pussy willow, dandelion, and fruit blossom.

THE ADVANTAGE OF SHELTER.

The best locations are usually found in valleys a mile or more in width, for such places are warmer in early spring than the higher lands. A spot of ground should be chosen in a sheltered nook; a clump of timber, a thicket of second-growth timber, or a ridge of hills on the north and west of the apiary will prove valuable.

The ground should be nearly level, but a gentle slope to the south or east is preferable.

THE HIVE-STANDS.

I make my hive-stands of cedar timber sawed into 16-inch lengths, and split into

Annual convention of the Southern Idaho and Eastern Oregon Beekeepers' Association held at Caldwell, Idaho, Feb. 9, 1912.

stakes about 2 inches square, which should be pointed at one end. Four hundred stakes are required for an apiary of 100 colonies. To arrange the hive-stands I go to one corner of the yard; drive two stakes 20 inches apart. I then drive two similar stakes at the further end of the yard, and stretch two lines between them, 20 inches apart. Then beginning at one end I drive four stakes, forming a level square 16×20 inches. I now move forward two feet and drive a second group of four stakes. The next space is six feet, so that the hives in the row will be in pairs. See illustration.

When I have reached the further end of the yard I take up the lines and arrange for the second row of stands, leaving a space of 12 feet between the rows.

SPRING PROTECTION AND SECURING WORKERS FOR THE HARVEST.

It is possible to have a good flow of honey and yet secure no surplus. The only protection I give my bees in spring is a quilt and tarred felt placed over the brood-frames and under the cover. Soon after the bees have a flight I look each individual colony over and note its condition. The small colonies are contracted to six combs by the use of division-boards. I make sure that all colonies have sufficient sealed stores to carry them safely through until May 1, when I get busy. At that time I make it my business to see all yards once each week. Just as soon as the brood-chamber becomes crowded with brood and bees I place over all such colonies a full-depth super filled with worker combs. The queen will soon

enter this super, and in a few days it will be filled with brood. When the bees are hatching freely in this super, which will be about May 25, I begin to build up the smaller colonies by drawing combs of hatching bees, and giving them to the small colonies. If it happens the small colony is so weak as not to have at least three combs of hatching bees I then exchange a comb of such bees with them for a comb of eggs. The eggs can be given to a medium-size colony.

It is my practice to have all colonies filling a two-story eight-frame hive with brood and bees by June 10, for at that date our harvest from raspberry begins. I now confine the queens to the lower body of the hive. To do this I remove the cover, give the colony a few puffs of smoke, thus driving the bees and queen below. I remove the super and place a queen-excluder over the hive-body. Over this I set a super filled with extracting-combs. I now look over the set of combs I smoked and removed; and if I find the queen I catch her and run her in at the entrance; then I put these combs on top of the extracting-combs. The colony is now three-story. Should the flow be a moderate one, the colony may not require any more supers; but if it should be fair to good, a third super will be required. Should more storage space be required I give it either by adding a third super or by extracting. If by extracting, I extract only capped honey. It looks nice to see hives tiered up with four or five supers of honey; but I think the bees store best when the hives are not more than four stories high.

Rapid City, Mich.

SOUTHERN IDAHO AND EASTERN OREGON CONVENTION

Shaking Foundation out of the Paper in which it is Packed

BY E. F. ATWATER

The annual convention of the Southern Idaho and Eastern Oregon Beekeepers' Association was held at Caldwell, Idaho, Feb. 9, 1912. There was a very good attendance of representative beekeepers, owning, in the aggregate, many thousands of colonies.

Perhaps nothing particularly new or valuable was brought out in the discussions, although the need of thoroughness in the eradication of foul brood was particularly emphasized.

The officers of the association for the year 1912 are shown in front of the group, seated. President, W. H. Pennington, the second from the right, is as practical a producer of extracted honey as any man in the northwest. Vice-president J. E. Lyon, long-time comb-honey expert of Longmont, Col., now of Idaho, is seated at the left (his daughter next to him), while at the right is R. D. Bradshaw, who is, perhaps, not behind the late E. W. Alexander in the successful operation of huge apiaries of 500 colonies and upward, in a single yard.

REMOVING PAPER FROM PACKED FOUNDATION.

One of the most tedious tasks that fall to the beekeeper is removing paper from foundation. Personally I have never seen any reason for the sheet of paper that goes with each sheet of foundation, unless it may, perhaps, serve to prevent breakage by imparting a certain cushion-like quality to the pile of foundation within the box. Certain-

ly I have shipped and received several hundreds of pounds of foundation not so papered, without loss.

But as the makers of the improved process foundation will paper it, a quick method of removing the paper is greatly to be desired, and such a method the writer originated several years ago, and has used since then with much satisfaction and saving in time. Perhaps the cuts and description will render it clear.

A pile of the double-papered sheets of surplus foundation is taken in both hands, as shown in Fig. 1, and shaken lightly, when the sheets in the lower part fall out. Now the lower part of the paper (now free from foundation) is seized and the remainder of the foundation shaken out as shown in Fig. 2. The foundation, free from paper, is now lying on the table, with the paper remaining in the hands, as shown in Fig. 3. The foundation must be cool, but not so cold as to break or crack easily. I see no reason why a similar method could not be used with brood foundation, if the makers would only make the paper about nine inches wide, so as to provide a place where it could be held while shaking out the foundation.

It is only fair to admit that I find some foundation that can not be freed from paper in this way—perhaps due to the fact that it has been packed so tightly in the box, or while too warm, so that the paper adheres tightly to the wax. Surplus foundation should never be papered by wrapping or folding each alternate sheet in paper, as has been done by some makers; for if packed by that plan, then there is no way to remove the paper except by the slow and tedious hand process, one sheet at a time.

Meridian, Idaho.

Wholesale method of removing paper from foundation.

WHY CERTAIN SWARMS DO NOT CLUSTER

The Story of "Giantess," of Forty-five Years Ago

BY A. I. ROOT

On page 284, May 1, is an article entitled "A Swarm that did Not Cluster." By some oversight a footnote was not added, to the effect that, when a colony of bees select a home before swarming, they seldom if ever stop to cluster on a limb in the orthodox way. My first experience in this line may be remembered by some of our oldest readers. After getting that \$20.00 queen of L. L. Langstroth I reared a large number from her the following season. One in particular was so very large, and had such an extremely prosperous colony, that I called her "Giantess" as a bit of pleasantry. Well, when white clover opened, my Italian bees were going in great droves off toward a piece of timber in the northeast. They not only made a great ado in the morning when they started, but there was such a roaring overhead that people thought my bees were swarming; and one morning I started out to find what called them off in that particular direction. I think I had a hive on scales at the time that was showing large daily gains. Sure enough, there were great fields, with an unusual crop of red and white clover, and every thing was going on swimmingly and to my great delight, until one bright morning in June, when clover was just doing its best, a great swarm issued from the Giantess' hive, and made a beeline without any preliminaries, circling off to the northwest.

I was so vexed and put out by losing this great swarm and that valuable queen that I declared I would have her yet if it was a possible thing. Of course my friends and

acquaintances who had laughed at me before on account of my enthusiasm laughed harder still, and joked about chasing runaway bees. I hired an experienced bee-hunter, the one mentioned in our A B C book; and as soon as the honey-yield was partly over so he could get the bees to work on "bait" he located the colony in the top of a large oak-tree a mile away in my father-in-law's woods. The tree was soon cut down, and the Giantess put into a hive and brought back home. This whole matter was given in GLEANINGS at the time, and numerous letters were received to the effect that bees often select a locality before swarming. Quite a number of careful observers had seen them going out and in holes and hollow trees, quite busy for several days before the swarm actually took its departure, led by the queen. The case mentioned in the communication referred to was one of this kind. The bees had made all arrangements for migrating to the new domicile by repeated visits each day for several days before the swarm came out; therefore there was no need nor sense in their clustering anywhere.

ARE WE READY FOR IMPROVEMENT OF STOCK?

Does it Pay Now?

From time to time articles appear in the bee papers on the desirability of breeding bees, or suggestions as to methods whereby this may be done. There seems to be a practical unanimity of opinion that, if we could but control matings, the bees would be vastly improved, and that the beekeeping industry would be benefited beyond our fondest hopes. That bees could be changed

and improved may be accepted as certain in view of the marvelous changes that have been made in plants and other animals.

The present article is written anonymously, for the reason that the thoughts herein expressed are not the opinions of the writer, but are merely questionings that have come to his mind. It would be a terrible blow to be credited with believing every doubt that may arise in one's mind.

Let us suppose a case. Two men in the basswood section of Wisconsin are engaged in producing comb honey. One has 150 colonies of fine stock which he is constantly seeking to improve, and actually is improving, by selecting his best queens as breeders. The other has 250 colonies kept in good condition; but he spends no energy or time in breeding. Assuming that the two men are identically situated and similarly equipped in apparatus and experience, and that they spend the same time in the apiary, will the first get 66⅔ per cent more per colony, and harvest as large a crop as his neighbor with the same labor?

Another case of A and B may be supposed. A is a breeder of fine bees, and maintains an apiary in Southern Michigan. He runs 200 colonies for extracted honey, and values his colonies at \$10.00 each because they are of superior stock. They have actually cost him that in time. B has his \$2000 in cash (and as much ability as a beekeeper as A), and goes to Kentucky to buy cheap bees. Five hundred colonies ranging in price from \$1.00 to \$2.00 in box hives are shipped north into a locality exactly comparable to A's. Coming as they do from further south they are stronger at the beginning of the clover flow than those in A's apiary. At the end of the supposed good season, A has a nice crop of honey. B extracts all the honey in

his colonies, melts up the combs, and burns up the boxes and poor hives which were used as brood-chambers. The wax is worth at least \$500, and with that start does it seem likely that A can close the season with as much cash as B has, over and above his original capital? If A clears \$10.00 per colony, it is necessary for B to clear \$4.00 plus the cost of the colony, and minus what he gets for the wax. It is a safe bet that A will work as hard requeening his prize apiary and carefully manipulating his colonies as B will with his 500 wrecks.

I have (supposedly) a fine apiary in Central New York. I must leave at least 30 pounds per colony for outdoor wintering, which is worth, at a low estimate, \$3.00. I can buy bees in Pennsylvania, and move them north for \$3.00 per colony in the spring; and on account of the more advanced season in Pennsylvania they will arrive actually stronger than I can get my own. If I kill my colonies after the honey-flow I save at least \$3.00 per colony, and get the wax. I eliminate winter loss as well as expense, and have nothing to worry me in the winter except my bank account.

Being nomadic I also own a string of apiaries in California. These too are composed of supposition colonies. I must leave 40 or 50 pounds to get bees through from one flow to the next. All around me are men who do not know what bees are worth. Shall I melt up my combs and buy new colonies next year and sell that honey for \$2.50 or more, and the combs for \$1.50?

My Uncle Tobias has an apiary of 100 colonies in Northern Indiana. His location would support more colonies, or he can improve his stock so that the same number will cover the territory. He probably gets on an average 75 per cent of the nectar.

New York State convention, held in January, 1912, at Syracuse, N. Y. A partial report of this meeting was given by R. F. Holtermann, page 177, March 15.

Dr. L. A. Simmon and his swarm controller connecting the entrance of the colony being treated with the "annex."

Will it pay him to increase or to breed to get the other 25 per cent? Not Uncle Tob. He is starting another apiary of 100 colonies to get another 75 per cent with about the same labor.

The point of all this is, are we ready for improved stock? Is it practical in the present undeveloped condition of the beekeeping territory to spend time on intensive beekeeping? There is more to this than breeding, for the same suggestions apply to many of the "advanced" manipulations. Much of the above isn't true, but it may be worth thinking on some winter evening.

Moral.—Mow the grass in your apiary if you wish, but don't wear it out by walking on it.

HOW TO CONTROL THE SWARMING IMPULSE WHEN ONCE ESTABLISHED

A Continuation of the Discussion Started on Page 137, March 1

BY DR. L. A. SIMMON

Every practical beekeeper knows the difficulty in controlling the swarming fever when once developed. Whatever method we employ must have for its object the gratifying of that desire in order to eliminate it. To illustrate the strength of this impulse, and the tenacity with which they cling to the desire and determination to swarm, I will cite the following example:

I had one colony that was used as a check in experimental work, that was not provided with the swarm-controller, but had abundant super room. This colony developed the swarming impulse in July. I cut out all queen-cells and depleted the working

forces by removing part of the brood, replacing with full sheets of foundation; and yet, about every two weeks I would find a new crop of queen-cells in the hive. On Sept. 19 I swapped queens with a colony whose bees had never swarmed. To day, Oct. 28, there are nine ripe queen-cells in this hive with the swarming queen, while the other hive, where queen-cells had been the rule for three months, but now presided over by a

non-swarming queen, is breeding well and has ceased to build queen-cells. This experiment would indicate that in this case the swarming impulse lies with the queen. It is not probable, however, that the queen always takes the initiative, for there are a number of auxiliary contributing causes that have their share of influence at times; and in order to check those influences they must be gratified, or, as in the case above cited, they will continue.

In any case, where adequate controlling measures have not been installed in time, and queen-cells have made their appearance in the hive, adjust your hives as seen in the cut. The right-hand hive is the cell-building colony. The left is the annex, which is filled with full sheets of foundation. The swarm-controller, which is attached to the annex, must have the rear chamber of the controller closed between the two hives by means of the slides, and the shutter at the back. The bees now have access to the annex through the front vestibule. This arrangement should be made two or three days previous to further manipulations, so that the bees will become acquainted with the new entrance, and have time to investigate the annex. When the queen-cells are nearly ripe, open the hives about noon; and after removing two of the frames of foundation from the left side, transfer two combs of honey and sealed brood with the queen from the right side to the annex on the left. Now close the entrance of the old hive leading into the front vestibule of the controller, and at the same time open the entrance of the annex communicating with the front vestibule. Next open the regular entrance of the old hive, or the one at the opposite end from the controller. The bees will now

Sweet-clover hay cut with a mowing-machine, and raked into cocks for curing.

take their flight from this new entrance, and return to the common entrance of the swarm-controller, and enter the annex, or hive on the left, where they find their queen and the conditions that satisfy the swarming impulse; viz., a new hive, combs to build, and relief from a crowded house. The supers should now be replaced, one over each hive.

Two courses are now open in dealing with the queen-cells in the old hive. They may be cut out and destroyed, or placed in nursery cages to be utilized in making further increase; or one of the choice cells may be left to hatch and become fertilized. If the first plan of removing all queen-cells be adopted, cells will require to be cut out again in eight days. The old colony will then be without material from which to rear a queen, and the entrance to the swarm-controller on the side next to the old hive may now be opened, and the regular entrance, or the one at the back of the hive, closed, compelling the bees again to work through the controller. Both divisions are now working from one common entrance; and, being of the same family odor, they will very soon intermingle; and, finding their queen on the left side in the annex, most of the bees will return to her, and the original conditions of the hive will be re-established, minus the desire to swarm, which has been gratified and eliminated.

Having two sets of combs now instead of one, the select combs are placed with the queen, and all others stored in the annex, where enough bees will remain to care for any surplus thus stored. If it is desired to save one choice queen-cell in the old hive

the same process of division is employed as above; and when the young queen is fertilized, having taken her flight from the extreme right of the old hive, this entrance is now closed, and the entrance into the swarm-controller opened. The two colonies now work from one common entrance, the front vestibule of the controller. After a few days place a queen-excluder over the old queen in the annex, and on top of the excluder an empty hive body. Transfer all the frames with their adhering bees and young queen into this empty super, over the excluder. Fill the old hive with frames of foundation, and allow it to remain as annex, and place all supers over the queens. We now have a double-decker with two hive bodies, two queens, and two supers, as seen in the cut. If it is not desired to work the two queens in this way, one of the divisions may be moved to a new location. If this course is chosen, both colonies should be sufficiently strong, and equalized before separating.

It will be observed that the first process controls the swarming impulse without making increase. The second process doubles the breeding capacity of the hive; but all the bees work together in common, storing in the one set of supers. The third plan divides permanently the working force, and is one method of making increase. The bee-keeper will be governed by conditions present as to which course to pursue. If the swarming impulse comes on during a great honey flow the first plan is obviously the one to employ as this will give the least possible break in the working forces. By placing a super over each division for the eight

days required, the bees will store nearly the same amount of honey as when working together.

Auburndale, Fla.

To be continued.

SWEET CLOVER AS A HAY CROP

BY FRANK COVERDALE

When I first began to grow sweet clover I had little thought of ever using it for a hay crop; but as time passed I began to see that it would answer very well as a dry feed. We experimented with one patch, and, contrary to what I had expected, a fine hay crop of superior quality was secured. This first field that we tried had been sown about the first week in May, and had been pastured to hogs until August, when all hogs were taken off. By October 10 the sweet clover stood 22 inches high, and then the mower was started. Just as soon as the hay was well wilted (but not dry enough to put in barns) it was raked into winrows and shaped into well-formed small cocks. These cocks, by the way, were just large enough so that they could be thrown on the rack in one good fork-load all at one time. This avoided scattering the leaves, which are as valuable as so much wheat bran. From this the reader will see the importance of putting up the hay so that it is not too dry when handled. All the handling, in fact, should be done while it is green and tough, when it can be gotten into the cocks before any leaves will be scattered around. It should stand in cocks until it is sufficiently cured to keep in the mow. We have always found that this clover has kept well when managed in this way.

White sweet clover is the worst of any of the clovers that I know of, to scatter its leaves when overdry; and the leaves being thick and meaty are surpassed by those of no other legume. A dairyman is lucky who has a good winter supply of first-year sweet-clover hay for his cows.

The cocks referred to will stand many rains and still be very good feed. Sweet clover sheds water better than common clover, and it has a smooth stem. The common red clover, because of its hairy stem, holds moisture, and quickly turns black and becomes unfit for feed. I have been happily surprised to find that this first-year hay cures the nicest of any that I have ever made.

This coming fall we shall have fully forty acres of this kind of hay to make, and we intend to use a side-delivery mower; and, when it is sufficiently dry, to use a hay-loader. We think we shall not have much loss when we follow this plan; and when there are large fields this latter plan is much faster than any other. There should be two wagons, one loading and the other unloading at the barn.

I know of no other clover that can be depended upon to make a good hay crop the

same year as sown. It has often been tall enough to mow in July; but at this time it would be very dangerous to mow it unless care were taken; for as yet there are no crown sprouts started; and if one mows the clover close to the ground in July, much of it will be killed outright. On this account, if one wishes to mow the first clover in July, or before the crown sprouts start, the machine must be set so as to cut high enough to leave stubbles that have a few leaves to make a start for the next crop. When the crown sprouts are started, the mower may be run close to the ground with perfect safety. These crown sprouts on the first-year crop will be seen close to the roots after removing about an inch of dirt. This is the reason, by the way, why this clover will not winterkill. The crown sprouts are about an inch below the surface of the ground, so that a covering during the winter is a certainty—a point of vast importance to one who is depending upon this clover the coming season.

MAKING HAY FROM THE SECOND-YEAR GROWTH.

Handling the second-year growth is, perhaps, a more difficult problem, as the clover gets very rank early in the season before good curing weather arrives. In this respect it is just like alfalfa. We have never dared to try and cure the hay until along in June; but at the same time every effort that we have made has been successful; we have never yet made a forkful of poor sweet-clover hay. With the improved variety of white sweet clover that we now grow, I am not sure but that we might cure the hay even as early as the 1st of June. If we could do this, the problem of making hay from second-year's white clover would be solved, and two good cuttings could be easily made during the second year, and a seed crop secured late in the fall.

There are many ways in which this clover can be handled for hay. One plan, which is very successful and easily carried out, is to wait until the clover is in bloom, and just beginning to form seed. This is just before the leaves begin to show yellow. While the foliage is still on, go over the field with a self-binder and set in shock rows, two and two. These bundles will cure nice and green, and will dry very quickly. They should be hauled and stacked like oats until winter, when the bands may be cut and the bundles thrown in the mangers for any kind of stock. It will keep perfectly dry if well stacked, and will make very satisfactory feed. The binder should be run high enough to leave behind a stubble which contains a few leaves, otherwise it will die out. If the leaves are left on, a nice crop of seed of excellent quality can be cut later in the fall.

Another plan is to pasture the second-year clover with some kind of live stock until late in May or the first of June. The hay will then be just about right in good hay weather, and can be made just as though it were a first-year crop. The stubble should be left high, as shown in the illustration.

It will be seen that some of the clover in the picture has not been cut well. In explanation, I will say that, just before we started to cut this hay, a new pitman arm had been put on the mower, and it drew the sickle too far one way, and hardly cut at all on the return stroke. If this had not been the case, there would have been a smooth top.

The cocks of hay shown were out in two showers, but nothing was colored except the outside. The middle cured to perfection, and went to the barn as green as tea leaves. This field was mown when just coming into bloom, and the stubble grew up and made a seed crop.

The reader may be interested to know that clover of any kind in this part of Iowa was very rare last year, as severe drouth had killed all other clovers except a little alsike here and there. Sweet clover grew as though there had been no drouth.

Delmar, Iowa.

THE WHITE FLOWERS OF NORTH AMERICA

BY JOHN H. LOVELL

White flowers are most common in our flora as well as in that of Europe, and 955 species occur in northeastern America. They contain no pigments. Like the snow and powdered glass they owe their color to their optical properties—that is, to the reflection and refraction of the rays of light by the minute cells of which they are composed. To produce a vast number of blossoms must, of course, tax the energies of a plant, and the absence of pigments lessens this expenditure. Like white leaves, I believe that white flowers are the result of retrogression or degeneration. Any brightly-colored flower may occasionally revert to white. Whatever impairs the vigor and vitality of the plant, as cold, impoverished soil, injury to the roots, or continued self-fertilization, will cause the floral hues to become paler, or change to white. I once transplanted a scarlet poppy when in bud, and the flowers became much smaller, and changed to pure white. White flowers are most common in the cold days of May, and gradually become rarer toward autumn. In the arctic climate of Spitzbergen the flowers are chiefly white, and there are few yellow and red, while blue appears to fail entirely. In East Greenland the flowers are likewise chiefly white.

On the other hand, whatever stimulates the growth of a plant, as bright sunlight, strong manures, or crossing, increases the brilliancy of the flowers. When lowland white flowers have been cultivated in the intense light of alpine heights they have in some cases become red. An application of nitrate of soda will increase the brilliancy of a flower; and tulips, when treated with strong manure, flush and lose their variegated colors. The brightness of the floral hues is also increased by crossing.

From this point of view we can under-

stand why white flowers are most common in nature, and why they are truest to name under cultivation. Naturally florists find that they can develop any desired color variety from a white flower more easily than from one already containing pigments.

Nature is an excellent economist. Trees and shrubs whose fruits are edible by man or birds usually produce their blossoms in boundless profusion, and they are almost invariably white, or nearly so—the two most noteworthy exceptions being the peach and the huckleberry, which have red or reddish blossoms. Among trees are the apple, pear, plum, cherries in variety, the quince and the orange; while among shrubs are the blackberries, raspberries, blueberries, the hollies, cornels, viburnums, and thornbushes. All of these species contain nectar, and are visited by honey bees.

There is nothing more beautiful in the floral vegetation of the world than an apple orchard laden with expanding blossoms. The great masses of flowers form billowing banks of whiteness, tinged with rose and flecked with the vivid green of the unfolding leaf-buds, from which exhales the well-known sweet fragrance of the apple blossom.

Spring walks abroad in all the fields to-day;

Her touch has left the apple orchards white;

The baby buds that waited for the May

Have shaken out their petals overnight;

Against the rugged boughs they softly press.

Weaving in the mantle of their loveliness.

Spring walks abroad with songs of life and cheer:

A thousand gifts she joyfully bestows;

But all her fairest handiwork is here

Where orchards toss their drifts of scented snows.

Alfred Russel Wallace, who spent many years of his life in exploring the vast forests of the Amazon and the islands of the Malay Archipelago, declares, "I have never seen any thing more glorious than an old crab-tree in full blossom; and the horse-chestnut, lilac, and laburnum will vie with the choicest tropical trees and shrubs." The cornels and viburnums are justly ranked among our handsomest shrubs, for the great clusters of white flowers transform the whole shrub into a huge bouquet.

The largest tree flowers known belong to the magnolia. One southern species has a white flower with a purple center which measures ten inches across. "Their effect in early spring is grand beyond description, illuminating the whole landscape and filling the air with rich perfume." Of the five northern species, four are white and one is greenish yellow. Magnificent white flowers are likewise displayed by several species of pond lilies; but very frequently white flowers are of small size, and conspicuousness is gained by their aggregation in masses.

Small densely clustered white flowers standing in the same horizontal plane, and affording a convenient landing-place for insects, are very common in the mustard, saxifrage, carrot, cornel, honeysuckle, and aster families. This type of flower cluster is excellently illustrated by the carrot family or *Umbelliferae*. To this family belong the

caraway and carrot, the wild parsnip, the water hemlock, and water parsley—plants growing luxuriantly by the roadside, along the river, and in the meadow. The flowers differ very little in structure, and the species can be identified only by the aid of the mature fruit. The nectar is secreted in a thin layer by a fleshy disc surrounding the style. Insects of every kind are made welcome, and no other family of flowers has so large a number and variety of visitors. On some species more than 200 different kinds of insects have been collected. The anthers and stigmas mature at different times, so that self-fertilization is prevented. Admirable simplicity and perfection are here combined. This type of flower is not, however, well adapted to honeybees, partly because of the scarcity of the nectar, partly because of the great number of other guests, and partly because the nectar on a flat surface can not be easily collected by long-tongued insects.

In the heath and huckleberry families there are many small white cup-shaped or urn-shaped pendulous flowers which are very attractive to honeybees and bumblebees. In the orchid, pea, mint, and figwort families there occur many irregular white flowers which have been derived from yellow, red, or blue ancestors, partly as the result of retrogression and partly, perhaps, because of the advantage arising from a contrast of colors between closely allied species blooming at the same time. Asa Gray is reported to have said that any colored flower might revert to white, and this is undoubtedly true.

Finally there are many very small white flowers which are solitary, or at least not densely clustered, which are of little value to the beekeeper. Some fifty-six such species belong to the pink family; they are low-tufted weak herbs of a spreading or ascending habit represented by the chickweeds and sandworts. They are chiefly visited by flies, beetles, and the smaller bees.

White flowers probably exceed all others in importance to the beekeeper. Says the A B C of Bee Culture, "We could better spare any of the rest, and I might say all of the rest, than our white clover that grows so plentifully as to be almost unnoticed everywhere." Besides the white and sweet clovers there are the buckwheat, button-bush, locust, palmettos, and a great variety of fruit-trees and berry-bushes. Scholl states that in Texas the sweet clover (*Melilotus alba*) and the common hoarhound are both important honey plants.

Waldoboro, Me.

patent and well known. Thus the male has no wax-pockets, for obvious reasons. Everybody knows it has no sting—not even a rudimentary trace of one. Wax-glands would be a superfluity, and therefore, wisely, they do not exist. A drone with a fully developed honey-sac would be an anomaly, because it carries no load of sweet nectar into the hive, and regurgitates no honey into the cells; yet it has a rudimentary honey-sac fairly developed. A true stomach it has; but the parts in the worker yielding the chyle food for the young are absent, and the whole of the four systems of gland structure are either absent, degenerated, or show only a trace of their existence. He does no work in the hive, for the very good reason that he is incapable of performing any, the tools with which these various labors are carried out having been denied him. The button, or spoon, on the point of his tongue has been atrophied, so that he can sip no nectar from the flowers. The rod is invisible on his tongue, therefore he can not collect honey; while if he could, the absence of the appliances for regurgitating the true nectar into the cells shows us he could not store honey, even were he capable of collecting it. His hind legs lack pollen-baskets, and he has no currycombs or pincers. Not having to take part in the elaboration of wax, its transmission from the wax-pockets by means of the pincers is not required of him. The saliva for bestowing on the scales fluidity or ductility can not be prepared by drones, neither can they use wax to construct cells or cap them. Appliances for converting the cane sugar of nectar into the grape sugar of honey would be useless, consequently they are wanting. The production of brood food and royal jelly are things impossible for these males, therefore in all drones the gland structures have been aborted, or, from the effects of sex selection, eliminated.

The worker bee is one of the most intelligent insects in creation, and is provided with a brain quick, subtle, and so far seeing that it must excite our admiration. Not only relative to size, but actually, the brain of the drone is much smaller, and especially does this hold good in the pedunculated parts where intelligence is chiefly originated. Every one knows the drone is far from having the credit of any great intellectual possession. The brain, indeed, has been atrophied in order that the sexual organs may be highly developed, just as the queen's ovaries have been perfected to the detriment of her intellectual powers. Nature often thus compensates one member of the body by the sacrifice of some less important organ.

Glancing at the body of a drone, let us now note a few points wherein he has been more highly favored than either queen or worker. In the head we find his compound eyes marvelously developed, as we shall see later, for a wise and necessary cause. His antennæ have each an extra joint, the queens and workers being provided with only twelve

THE DRONE AS COMPARED TO THE QUEEN AND WORKER

BY D. M. MACDONALD

Some points wherein there is a distinct differentiation between the drone and the two other orders of the bees in the hive are

joints to the male's thirteen. These mysterious "feelers" are also more profusely provided with "smell hollows," no fewer than of these being found on the two antennæ. They are indeed crowded together so closely as to give little or no room for the tactile hairs. For the male which is to seek the female, this is exactly what might be looked for. He possesses sixteen spiracles instead of fourteen, and thus his air-sacs are enormously developed. He has a very large spread of wing compared with that of the queen or worker while the hooklets number 24. Various other organs are more profusely covered with hairs than those of either queen or worker, and this is particularly noticeable on the front of the face, the hairs on the jaws, the feathered hairs on the digiti, the first dorsal plates, and on various parts of the abdomen. His one duty requires that he be highly fed, for only concentrated food can fully develop the contents of his spermatophore; therefore he feasts like any gourmand and lives the life of a sybarite.

If we consider the one duty of the drone's life, that for which he has been called into being, we shall at once appreciate the reason for the special development of his wing powers, the extra perfection of his antennæ, the abnormal size of his compound eyes, and the enormous number of his smell-hollows.

The drone's powers of vision and of flight are magnificent. His splendid compound eyes are admirably fitted for carrying out the one duty and function of his existence. Occupying almost the entire space on both sides of his head and a great part of the front, they are excellently adapted to assist him in carrying out his great work to perfection. In his flights through the air their immense magnifying powers enable him to pierce with keen vision the liquid blue, and so he is enabled to detect any royal virgin out for her nuptial flight, while all three ocelli, or simple eyes, placed in a close cluster right in front of his forehead, closely observe her every motion, and follow minutely every movement in her quick aerial flight. Rapid as is her progress in the pure ether, his powers of flight excel, though only in this case one out of (it may be) a thousand. Swiftly and unerringly, therefore, he pursues her until he brings about the great consummation of his existence. Those who stupidly and erroneously designate him a lazy drone should see him then, when every muscle is strained to the fullest tension, when every nerve is strung to its utmost powers; when every thought and sentiment of his being is focused on one object—to outstrip all rivals and be the first to reach the goal of his and their longings.

The race is here to the swift! All puny, weak, or starveling males; all who are small, feeble, or delicate; those undeveloped, dainty, or luxurious; and all sickly and infirm, each according to the want of vitality, drops out of the race at an early stage until only the virile, vigorous, and manly remain.

At length only a tithe of the most powerful and best developed remain as royal suitors. At last only the fittest survives and becomes the means for perpetuating the race. Here is a scheme magnificent in its conception, exquisite in its development, and perfect in its fulfillment.

Tennyson tells us that out of a thousand seeds "Nature doth make but one to bear;" and so it is with the drones in our hives. Their great number is easily explained by the fact that the queen has to go abroad on her marital flight, and that only after a prolonged and risky journey in the air does the chosen suitor meet her. Nature thus secures by an almost invariable law the survival of the fittest.

As is well known, the drone takes 24 days to develop from the egg to the perfect insect. While the egg hatches, in the ordinary, in three days, he is fed as a larva for an extra day. He takes three times as long as the queen to spin his cocoon, and continues more than double the time in the nymph stage. His food almost from the first differs. His natal cradle is much larger than that of the worker. He is fed all his life, but on a food different from that fed the queen; yet the workers highly pamper him. His voice is different, and the deep sonorous sound of his flight can never be mistaken for that of either of the others. Having no sting he can not well defend himself, and is, therefore, at the mercy of the smaller females when they wish to evict him. These subtle ladies, however, get rid of him by simply withholding the chyle food, formerly lavishly supplied, when they considered the fate of the hive might hinge on his act. Small though they are, bulky though he is, they are the masters; and when the fit time arrives for sacrificing these now useless intruders they ruthlessly carry out the act without the least compunction.

The drone was a mystery to the ancients. Why, they pondered, should a class of idlers exist in a community where all others are workers? Why should they be consumers where the workers are all producers? Being the greater bee, why should he be in subjection to the smaller? Why should they be so ruthlessly evicted? Were they simply nurses? "They sit on the cells as a hen doth on her eggs," wrote Hill. Were they bees which had lost their stings? Were they captains acting under orders of the king? Were they really a redundancy of nature? Virgil asserted that they brought the seeds of the young from the flowers. Butler came near the truth; but 150 years after, Rusden thought their great work was "sitting on the eggs." Later, Huish held that every egg is visited by the drones in the hive, and dealt with. It was only about a century ago that the researches of Huber and succeeding investigators convinced beekeepers that the only reason for the drone's existence is to fertilize the queen—which conclusion will never be questioned.

Banff, Scotland.

Heads of Grain from Different Fields

Square Beeway Sections v. the 4 x 5 Plain

1. In comparison, all points considered, for comb honey, what advantage, if any, has the $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ over the $4 \times 5 \times 1\frac{1}{2}$ section?
2. Is there a preference on the part of the retailer of honey? Why?
3. Is there a preference on the part of the consumer? Why?
4. Which size stands shipping best? Why?
5. Do you consider it difficult to secure proper grading weight in $4 \times 5 \times 1\frac{1}{2}$ sections and not have honey project beyond the wood?
6. Is there any complaint that the average person handling honey bruises or sticks his finger into the 4×5 more than the $4\frac{1}{4}$?
7. Is there any difference in price of honey, one over the other?
8. What section do you advise one to start with? Why?
9. Does comb honey ship safely long distances when packed in carriers, eight cases each?
10. Is there any advantage in packing or placing each section in a carton and using the heavier shipping-case?
11. What effect will the National Association have in recommending the $4\frac{1}{4} \times 1\frac{1}{2}$ over or against the $4 \times 5 \times 1\frac{1}{2}$?

Hagerman, N. M., Jan. 30. HENRY C. BARRON.

[1. This involves the consideration of plain sections and sections with beeways. A $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ is a beeway section, while the $4 \times 5 \times 1\frac{1}{2}$ is a plain section. The plain sections are cheaper in first cost, a little easier to scrape and clean of dirt and bee-glue, take a little less room in the shipping-case, and, in the minds of a good many, present a little nicer appearance, because the comb itself comes out a little more nearly to the edge of the wood. On the other hand, there are those who object to plain sections because they are more difficult to get out of the shipping-case, more danger of abrading or damaging the surface of the comb in removing from the case, because fence separators for the plain sections are more expensive than the separators for beeway sections, and because, under some conditions during a heavy flow of honey, a small percentage of the honey will take on a washboard unevenness. This last objection is not a very important one, because only about two to five per cent of all the honey so produced will show this. There will be a larger percentage during a heavy flow of honey or in the case of extra fancy or well-filled sections.

The next question naturally revolves around the shape or size of the section. The $4\frac{1}{4}$ square is an old standard dimension. While the 4×5 or $3\frac{1}{2} \times 5$ is a newer style that was introduced in New York by Capt. J. E. Hetherington, it has come to be used quite largely now, because any article of food looks better. It is contended, that is taller than broad. The tall section is only an effort to cater toward making the package conform to all other packages holding food on the market. Pound for pound, a tall section looks larger than one that is square; and in the case of the 4×5 the section looks a great deal larger because it has a thinner comb than that in the $1\frac{1}{2}$. Again, it is argued that the bees will build out and finish a thin comb faster than they will a thick one. The experience of many buyers is that the combs in the 4×5 sections are more solidly attached than they are to the $4\frac{1}{4}$ square. Part of this is due to the thinner comb which the bees attach better, and part to the fact that there are longer vertical sides for attachment.

2. The answer to this question depends somewhat upon the locality. In many parts of the East the 4×5 section is preferred to the square one, while in the West the $4\frac{1}{4}$ square section is used almost exclusively. In many of the Eastern cities the dealers prefer the 4×5 sections. They claim that, when the square sections and tall sections are put side by side, the tall sections will outsell the square every time. On the other hand, there are some dealers who claim they notice no difference, and that customers will buy whatever is offered them.

3. This is partly answered in No. 2. As a general thing, we think we may say that, of two sections evenly filled, the customer will take the tall section because it looks larger for the same money. It is for this reason that the tall section brings a higher price in some markets than the square.

4. It is our experience that there is not a great

deal of difference; but the difference, if any, is a little in favor of the 4×5 section.

5. The answer to this question will depend somewhat upon what is the proper grading weight. The 4×5 section does not run a full pound as a rule, unless filled very full. In any case the comb should not project beyond the wood if the proper kind of fence separator is used.

6. Yes, the 4×5 section is liable to be damaged a little more than the $4\frac{1}{4}$ square; but there is no excuse for an employee or clerk punching his fingers into either section.

7. The 4×5 sections in some markets in the East bring more money than the $4\frac{1}{4}$. As a rule we think the prices run about even.

8. This will depend somewhat upon the locality and the market where the honey is to be sold. We would carefully ascertain what is the general demand in the nearest market, and adopt the section that seems to be called for the most.

9. Yes, providing plenty of straw is used under the cases.

10. Yes, the cartons have a tendency to cushion each individual section so that it does not receive the shock during shipment that it otherwise would. We also think it is an advantage to use a stronger and heavier shipping-case. For a further discussion of this general question, see GLEANINGS, page 361, of our June 15th issue, 1911.

11. It will probably have some effect with a few members; but in most cases the producers will be governed by what is called for in their markets, irrespective of any recommendations made by any bee journal or any beekeepers' association.—ED.]

Swarming a Natural Instinct of the Bee

To my mind the cause of swarming may be given in a very few words. It is the instinct which God gave the bees when he created them, in order that they might increase. If the bees had never swarmed they would not be scattered over all the face of the globe to-day.

Wm. Beucus, Aug. 1, 1911, says that the building of queen cells suggests the idea of swarming. For my part I would rather think that the idea of swarming should account for the building of queen cells. I do not believe that bees ever build a queen cell before they have the idea of swarming.

It is certain that if they never build a queen cell, and if man lets them alone, they will never cast a swarm. But when one sees queen cells started he knows at once that the bees are preparing to cast a swarm, so they must have the idea of swarming in order to cause them to start queen cells. Sometimes, of course, they build queen cells when they wish to supersede the old queen, but not at all with the idea of swarming.

Bees Slow to Enter Supers

My bees will not store any honey in the brood-nest, but want to go into the super all the time. If they fill the super next to the brood-nest, then they want to swarm unless more room is given; and at the end of the season, in order to make sure of plenty of stores, I have to leave the extracting-super on the hive. Then in the spring they begin brood-rearing in this shallow super. How can I make use of winter stores in the brood-nest?

Shelbyville, Mo.

C. H. HOLLYMAN.

[Your question is quite unusual, for most beekeepers find that their bees are slow about entering the supers, and persist in storing in the brood-combs, thus cramming the queen for room. We really believe that this tendency on the part of your bees is a fortunate one; for by keeping good prolific queens you can have your colonies up to the maximum strength by the time the main flow begins. By raising the nearly completed super and putting an empty one underneath, and also providing some upward ventilation, if necessary, during the hottest weather, we think you can overcome to a certain extent the swarming. Of course you can not prevent it all when running for comb honey.

At the end of the season remove the super; and then in the fall, if there has been no late honey-flow to provide winter stores, feed the necessary amount of sugar syrup, and the bees will be obliged to store in the brood-combs.—ED.]

How Hot is the Steam-heated Knife?

I am thinking of getting one of those steam-heated uncapping-knives, but am a little doubtful as to whether it is any thing better than what we have been using. Can the steam-heated knife be kept hot enough so that it will be too warm to lay the blade on one's hand? Does not the steam-tube get in the way much of the time?

We had bountiful rains through March and so far this month, and the prospects seem fair for more. I don't know much about my bees, having been in poor health all winter. The few stands I have here at the house are in good order.

Hemet, Cal.

B. H. HUDSON.

[We have tested steam-heated knives very carefully and thoroughly at Medina. As to whether this form of knife would be more satisfactory than knives that are constantly dipped in hot water will depend somewhat upon circumstances; but we would say very decidedly that in any case where a knife works better because it is hot, a steam-heated knife will be far better than one that is dipped in hot water every minute or two. A steam-heated knife will remain so hot that you can not bear the back of your hand to the blade at any time. It has the advantage that you can keep right on uncapping, and the cappings will fall off without any sticking to the knife itself.]

The objection to the steam-heated knife is that the tube interferes a little with the free handwork; but after one becomes accustomed to working the rubber tubing he does not find it any great inconvenience. Another objection is having the little oil-stove in the same room. Sometimes the room where the uncapping is carried on is very small and quite hot. This little stove has a tendency to heat up the room; but if you have an oil-stove for heating the water for your knives, this objection would not really be against the steam-heated uncapping-knife. In a word, we would say that, where it is an advantage to use a hot knife, you will find the steam method of heating the knife far superior to the method of constantly dipping in hot water.—ED.]

No Loss in Alabama Apiary Except Laying-worker Colony

In reading the reports from different States in regard to winter losses we see no report from Alabama. Our bees came through the winter in good order, and are moving right along rearing brood. We did not have a single loss, with the exception of our laying-worker hive which we treated with sulphur.

CONSUMPTION OF HONEY AVERAGES $7\frac{3}{4}$ POUNDS PER COLONY.

On p. 153 Mr. Crane refers to Mr. Mollett's saying that it takes from 50 to 75 pounds of honey to winter a colony of bees. We don't know what part of the South Mr. Mollett lives in; but it seems to us that that amount of honey is too large an estimate.

Here are a few figures from our book. We weighed our colonies Nov. 15 and again March 1, and no one colony consumed over 12 pounds, and the average consumption was $7\frac{3}{4}$ pounds during that time. Now, we fail to see where such a difference arises. Possibly it is on account of his "locality."

Cooling Hives in Extremely Hot Weather by Spraying with Water

I heartily indorse the method of shading hives with boards on hot days. The method was first suggested to me by an old bee man here. On one occasion, early in April, he lost several stands through negligence in using his customary shade-boards. The comb melted and destroyed the bees. Last summer, when it was somewhat dry, I sprinkled my hives all over with water. I used an ordinary sprinkling-pot holding about a gallon, and added a tablespoonful of salt to each gallon. The evaporation cooled the hives.

Suffolk, Va., Dec. 30.

W. T. BAILEY.

How to Avoid Killing a Large Number of Bees when Putting on Supers

I have studied the bee business for eight years, but never saw in print one particular trick of the trade; and that is, how to avoid killing a good many bees when putting on supers or other fixtures. It works well to put one end of the super

down an inch forward and one inch to the side of the desired position, and to let the other end down slowly, shaking it meanwhile to let the bees get out of the way. If the hands are then placed at opposite corners of the hive with the fingers on the lower story and the palms on the super, by levering between the fingers and the palms one can easily slide the super into place. By reducing the contact surface, fewer bees are killed.

Lakeside, Cal.

G. E. PHILBROOK.

When and How to Have Foundation Drawn Out

I shall have a large amount of foundation to draw out this season. Could you tell me the best steps to take to get it drawn out as early as possible, so as not to tamper too much with the clover crop?

Guelph, Ont., April 13.

FRANK E. MILLEN.

[The only way you can have foundation drawn out before the general honey-flow is to feed with sugar syrup, half a pint to a pint daily. You may have to use more than this. This will be a very good stunt for you, because you can get the combs drawn out and filled with sugar syrup; and then when the honey-flow actually comes on, every bit of the clover will go right into the sections or supers. This is the plan that was advocated by H. R. Boardman a few years ago.—ED.]

Death of Jesse W. Thornton

On April 9, Jesse W. Thornton, ex-president and vice-president of the Washington State Beekeepers' Association, died. He had been ill for some time, but seemed to be feeling better the day he died, and was putting on his coat to go to the city when death overtook him. He was 62 years of age, and leaves a wife, one daughter, and five sons to mourn his loss. He was a minister in the German Baptist Church. He was quite an extensive beekeeper, owning about 200 colonies, and working about as many more until quite recently. He was also a member of the National Beekeepers' Association.

North Yakima, Wash.

J. B. RAMAGE.

Controlling the Clustering-place of Swarms with a Kerosene-soaked Mop

I have read that has been said about carbolized cloths. As my yard is located at the edge of timber land I have used kerosene successfully when swarms have clustered high. I shake the cluster off and sprinkle kerosene oil with a paint-brush around the spot. I also keep a very long pole in the yard, to the top of which is fastened a mop-rag soaked in kerosene. If a swarm attempts to cluster high I raise my pole so that the rag is near them, and usually their next stopping-place is lower down.

Swanville, Minn.

JOHN S. LIND.

Cramps from Eating Honey

For years I did not eat honey, on account of its doubling me up with cramps, page 226, April 15, yet there was nothing so tempting as hot biscuit, butter, and honey for breakfast. After I got bees, and there was plenty of honey around, I could not keep from trying it, and now I eat honey when I want it. Many a healthful breakfast I have of honey, biscuit, and butter, with hot-water tea. It is simply getting used to it.

Galena, Kan., April 18.

J. P. BRUMFIELD.

Colonies Wintered Successfully on Honey-dew

A few years ago I made two winter cases after a pattern I saw in GLEANINGS, to be packed with leaves or sawdust, with a three-inch entrance and tin slide to exclude light. Last summer my bees gathered some honey-dew. Mr. A. C. Miller said they would winter well on honey-dew with plenty of air, so I set them in the empty cases, gave them the width of hive entrance, and the third wrapped in red building paper. Each had a super of dry leaves and 3 lbs. of granulated sugar, but little honey. March 29 they were in fine order.

Information Wanted in Regard to the Aspinwall Hive

I should be pleased to hear from those who used the Aspinwall hive the past season.

Easton, N. Y., April 19.

E. M. SLOCUM.

Our Homes

A. I. Root

Belshazzar the king made a great feast to a thousand of his lords, and drank wine before the thousand.—DANIEL 5:1.

In the same hour came forth fingers of a man's hand, and wrote over against the candlestick upon the plaster of the wall of the king's palace; and the king saw the part of the hand that wrote.—DANIEL 5:5.

Then the king's countenance was changed, and his thoughts troubled him, so that the joints of his loins were loosed, and his knees smote one against another.—DANIEL 5:6.

Thou art weighed in the balance, and art found wanting.—DANIEL 5:27.

In that night was Belshazzar the king of the Chaldeans slain.—DANIEL 5:30.

If you have not read the fifth chapter of Daniel recently I wish you would all take a Bible now, or the first opportunity, and read that chapter. Babylon was at that time besieged. If there ever was a time when the king and all his people needed all the wisdom and sense God had given them to protect their city, it was on that very night. If I am correctly informed, the enemy were at that very hour busy in changing the course of the Euphrates River, and they had just succeeded in making the river-bed dry so that the soldiery could march unhindered through it into the city. The first verse of our text tells us that this heathen king, at a time when he *should* have been wide awake, and on the alert, was conducting a great banquet or feast, surrounded by a thousand of his lords; and he drank wine—probably the most expensive kind that the world could furnish at that time. We are told many times in the Bible that, although the great Father suffers long and is kind, there comes a time when he punishes not only individuals but cities and nations; and his rebuke and punishment are often so severe that the whole wide world sits up and takes notice.* The king was awakened from his drunken orgy by a mysterious hand writing on the wall. No wonder his knees smote one against the other. Good faithful Daniel hesitated not to tell him what it meant—"Thou art weighed in the balances, and art found wanting. Thy kingdom is divided and given to the Medes and Persians." On that same night, probably before he had fully awakened from the effects of his drunken revelry, the city was taken and the ungodly king was slain.

Now, when I apply the above well-known incident to the tragic fate of the Titanic you may think my illustration is severe and unwarranted. Let us look at it a little. From the very first I decided that the terrible curse that is resting on our nation (and the whole wide world just now more or less) was responsible for the fact that that great vessel was plowing along among the icebergs at railroad speed. What else could account for such unwarranted and unheard-of course

of action? You have all read, perhaps, over and over, the accounts of the tragedy. It was after we had had several newspaper accounts of the event that I found in one corner of a daily an intimation that some of the officers had been *drinking*. Then it came out little by little. The only man on the lookout, when he was more needed, perhaps, than ever before in *his life*, was *asleep*. Another item some days later informed us that the lookout officer on that great steamer, costing toward ten millions, had not even a *field-glass*. The pilot or lookout had *lost* the glass belonging to his post; and when he applied to the proper authority I think that this "authority" must have been drinking also, for the pilot was told that "none would be furnished" him. Other vessels in that region were crawling along slowly, and taking every precaution to avoid accidents from icebergs. I know a little about the matter, for my youngest daughter was on a ship when it struck an iceberg; and, although the motion of the vessel was slowed down to almost nothing, it tipped the vessel over on its side, and made such a consternation that those on board will never forget it. Lest you think I am misinformed, permit me to give the following extract from the *American Advance* for April 27:

As the press showed indications of covering up the seemingly well-founded report that the Titanic went to her death because of drunkenness aboard, *American Advance* wired to Dr. A. S. Gregg, Field Superintendent of the International Reform Bureau, to find out the facts. He wires, as we go to press:

"Louis Klein, a Hungarian seaman of the Titanic crew, who came here in search of work, immediately after the landing of the survivors of the wreck, has made a statement to the Austro-Hungarian consulate and to the federal authorities, charging that some men were drunk and that the only man in the lookout of the Titanic was asleep at the time the ship struck. He says the stewards had given men champagne from partly empty bottles. Klein was taken to Washington last night by a deputy United States Marshal to testify before the Senate Committee which is investigating the Titanic disaster."

American Advance has taken steps to have a staff correspondent on the ground at Washington and in attendance at the Senate Committee's hearings. We intend to probe the matter to the bottom, uncover the full facts, and we will not stick them away in an obscure corner of the paper, either. We have no liquor advertising to lose.

"The night the ship went down," said Klein, according to dispatches from Cleveland, "I was doing patrol duty on the promenade deck, starboard side. I took the watch at 9:30 o'clock, and was to keep it for six hours."

STEWARDS SERVED WINE TO MEN.

"There was a ball following a banquet of some kind going on in the saloon, and the captain and

* We copy the following from the *Scientific American* for April 27 in regard to the disaster:

"How such an experienced commander as Captain Smith should have driven his ship at full speed, and in the night, when he knew that he was in the proximity of heavy ice-fields, is a mystery which may never be cleared up.

"That underwater blow, deadly in its nature, would scarcely have been fatal had the ship been put, as she should have been, under half speed."

* He will not always chide; neither will he keep his anger forever.—PSALM 103:9.

the officers were there with many of the passengers. I thought the White Star Company was connected with it somehow. After the party the stewards served to the crew the champagne and wines that were left. I knew that many of them were drunk."

Let us now investigate a little in regard to the "drink" they had on that occasion, and see what was going on. First and foremost, it was on God's holy sabbath day. I wonder how many even *tried* to "remember" that sabbath day "to keep it holy." There was a ball following a banquet of some kind, and the captain and officers were there with many passengers—probably the *millionaire* passengers, of whom there were several. Women were rescued who had on their ball-room costumes that Sunday night. They had the most expensive drinks. I do not suppose the readers of GLEANINGS even know what a bottle of the best and highest-priced champagne costs. I am glad to confess I have never tasted champagne. I once saw a miserable drunken sot, but whom I judged by his clothing and diamonds and senseless jewelry to be a millionaire. I ran on to this poor creature in the smoking-room of a Pullman car. I never even go through the "smoking-room" if I can help it. This man, with his bloated, livid, wrinkled face, which was in striking contrast to his flashing diamonds, had just opened a bottle of champagne; but his poor shaking hand would hardly permit him to pour the foaming stuff into the glass. With eager haste that made me think of a starving man he tried to get the foaming liquid to his lips; and when he did so he acted like a drunken man catching at a straw for safety or relief. I have seen the price of champagne on the bill-of-fare on Pullman cars. Thank God it is banished from the greater part of them now. I remember seeing it priced at several dollars a bottle. A friend tells me the price is usually five dollars *and up*. There are thousands of people starving at the present time, not only in foreign lands, but many who, in consequence of the recent floods, are probably suffering from a lack of food in our own nation. Now, what do you think of a man or woman who will drink champagne at such a price when people just as good and praiseworthy in every way, near by, perhaps, are suffering for food, or, say, for a drink of milk? No wonder there is war, especially in our great cities, between labor and capital. The *Advance* suggests that the daily papers suppress the matter of drink on account of the liquor advertising they carry. Let me digress enough to say right here that I am about ready to declare I will never vote for another candidate for President, Governor of the State, nor for a public official of any kind, who has not the manliness and courage to come out squarely against the liquor-traffic.

Just one thing more about champagne. We read between the lines that it flowed as freely as water. Indeed, these drunken millionaires, some of them probably like the wretch I have described, had all they could drink (of this *expensive* wine) and more too; and out of the kindness (?) of

their hearts they sent the partly emptied bottles down to the under officers, kindly remembering the good lookout at his post while they were coming into the region of icebergs.

But, thank God, there is something to be said in the way of praise for the men on board of that ill-fated ship as well as criticism. When they were thoroughly aroused from the effects of the drink they began to look up the lifeboats. It was supposed to be such an impossibility to sink *this* vessel that the customary equipment of life-savers was cut down very much. I presume few thought there was much danger of the vessel going to the bottom—*two miles* to the bottom. This was a British ship. The crew were supposed to be under British drill, and they were a manly set of fellows besides. For safety the women and children were put into the lifeboats, with the exception of a few women who would not leave their husbands. Dear reader, probably you have never been in such a predicament. I have tried to face the question myself. Would Mrs. Root consent to step into a lifeboat and leave *me* to go down? I have not asked her; but I know without asking. She would declare in an instant that she would stand by my side in the hour of trial. My conscience troubles me to think how poorly I have remembered the oath I took to love, cherish, and protect *her*, before God and man; but when she made the same promise before God, she has for over fifty years lived up to it to the very letter. I might try to persuade her that, for the sake of the children and grandchildren, she should save her life. I might tell her I could swim and keep afloat long enough to be able to be picked up; but I do not think she would listen an instant. Thank God for these devoted, loyal, Godlike women. Mere gratitude to them for what they have done is the smallest debt we owe them. And those men, something like 1600 of them, showed their manhood and courage by unflinchingly facing death. The band played, "Nearer, my God, to thee," and kept it up until the water was up to their knees. I think one report states that the final strains of that grand old hymn (written by a woman) were given from their instruments on bended knees. If I remember, the captain of the ship rescued a baby and got it on board of one of the life-savers. He refused to be pulled in himself, even though there was room. I suppose that he and the rest of them reasoned that, when the men should see them climbing into the boats, others would try to follow, and the boats would be swamped. Some who were saved on a sort of raft made of the broken collapsible boat tell us that there were *prayers*, not only from many who never thought of praying till then, and some who knew no other form of prayer, repeated the childish ones taught them by faithful Christian mothers at the mother's knee. Whatever we may say in criticising the carelessness and the unwarrantable speed at which the

vessel was running amid dangers of that kind, let us remember the heroism and manliness of over a thousand men who, having done every thing possible to save the helpless women and children, calmly and unflinchingly faced death.

I think the tragic events narrated in the fifth chapter of Daniel must have had a wholesome effect on the people of that day and generation. The Iroquois Theater disaster in Chicago in 1903 had the wholesome effect of stirring up the whole city and other cities to the importance of remodeling great auditoriums. The Slocum disaster, six months later, when about a thousand men, women, and children, were burned to death and many drowned near New York, caused a general housecleaning and overhauling of excursion boats. And, later still, when a school at Collinwood, near Cleveland, caught fire and burned up about 180 children, a wave of reform went all over our land and over all the world. Even down at Bradentown, Fla., a hurried consultation of school directors was held, and our two-story wooden schoolhouse was speedily alive with carpenters, on one side at least, and a wide outdoor stairway was built up to the second story, equipped with doors that swing outward, so the hundreds of little ones there gathered could get out speedily and safely in case the wooden structure should take fire. I mentally thanked God every time I passed that stairway on my daily trip with the automobile. Again, a year ago last March a large factory burned in New York, resulting in the death of about 127 people, mostly young women. All escape except at the windows was cut off, and again the world was horrified by what happened, and incensed to think how easily the trouble might have been averted. But it led to an overhauling of buildings in that great manufacturing center, which may be the means of saving more lives than were lost.

Last Thursday evening here in Medina my heart was rejoiced to see almost a hundred people at our weekly prayer-meeting. I told them that I had been praying for our prayer-meeting, and inviting people to come, *for nearly forty years*, and the answer to those prayers had come during my absence last winter. Well, I was greatly touched by the young man who led the meeting. There seemed to be such a feeling of sadness and sorrow in his countenance, together with his bright shining face as he unfolded the glorious promises of the lesson before us, that I thanked God. After I got home I was told that his only little girl perished in that Collinwood fire, and the look of sadness had never been noticed until after that terrible event. It seems necessary, sometimes, in order to bring about needed reforms, and to rouse up poor sluggish humanity, that many must die as martyrs to the good cause. May God help me to be ready to die, should the time ever come, when I am needed as a martyr to the cause of spreading temperance, righteousness, and the gospel of the Lord Jesus Christ.

WIRELESS TELEGRAPHY, ETC.

Without wireless telegraphy, which seems to be making such wonderful strides just now, probably not a soul would have been saved from the Titanic in that fearful tragedy I have just been describing. Almost constantly we are hearing news of rescue on the sea by means of this wonderful means of wireless communication; and a recent issue of the *Scientific American* informs us that wireless stations are now to be set up or are being set up so as to compass the whole globe on which we live, or at least such a part of it as constitutes traffic on the sea as well as on land. Dear friends, do you ever stop to consider what the outcome is going to be if great inventions keep on during the coming fifty or sixty years as they have in the past? I can almost remember the advent of railways, great steamships, telegraphs, etc., and many of us of middle age remember when there were no electric lights, no telephones, no photographs; and even the children remember the time when there were no moving-picture shows nor flying-machines. What is coming next? It is evident that God is *now* working out his plans for humanity—plans conceived, perhaps, ages ago. Has he been waiting for us to rouse up and wake up? You and I both have seen boys brought up on the farm, or in humble homes. There was nothing in their boyhood or childhood to indicate more than ordinary ability, and now they are scattered over all the world, *some* of them occupying great and important positions, and drawing salaries *unheard* of a few years ago. Again I ask, *what is coming next?* Are we going to explore the inhabited planets? and *finally* is the great Father in his mercy, love, and goodness, letting us get just a *little* glimpse of the great unknown, *beyond* the confines of *this* transient pilgrimage?

FLORIDA INVESTMENTS.

All winter long I have been getting letters, more or less, from all over the North, from people who wanted my opinion regarding purchasing real estate down here. These people often give me a list of bargains that have been offered them, and refer to or submit the circulars and descriptions, etc. Sometimes they ask which *one* they had better invest in. My advice has been right along, don't invest in *any* of them. Do not under any circumstances think of investing in anything down here in Florida or Texas, nor anywhere else in the way of real estate, until you go and look it up yourself. Don't depend on somebody else. Some time ago there was much said about St. Cloud, a home for the "old soldiers," etc. A brother-in-law of mine has just returned from there, and gave me some points. He could hardly find words to express his indignation at the people who had swindled old soldiers by getting them to go down there and make investments. It is true that, while the excitement is high, and while the "gamble"

is going on, there is sometimes a chance to invest money, and perhaps get it back and more too. As an illustration, a brother of his invested \$100 without seeing the property, several years ago. A year later he was offered \$400 for the particular lot he had purchased. As there seemed to be a prospect that it would go still higher he did not sell out. Now, however, he would be glad to get back the original \$100 he invested; but as there are hundreds in the same predicament there is no *possible* chance of selling out at any price. St. Cloud is only an illustration of many other speculations of this kind. The "syndicate," or whatever you call them, by buying large plots of land bought some of it as low as 80 cts. an acre. They divided it up and made their lots, did a lot of advertising, and sold it for thirty or forty *dollars* an acre. If they could sell all these lots at the prices they had planned, making a city something like New York, for instance, it *would* be a big thing. Bubbles like these are being started and exploded or burst all over Florida and other States. By shrewd advertising and investing considerable money they can keep the thing going for a little while; but the outcome of the biggest part of such speculations is an abandoned town. Another thing, buying and *selling* real estate is a trade of itself; and if you have not had any experience in it you had better let it alone. *Still* another thing, a good deal of it is really *gambling*. Frauds and swindles have been so frequent in connection with the "Everglades," which you probably all read about, that the Department of Agriculture at Washington has

taken the matter in hand. Quite a few beekeepers who call to see us confess that they have invested in Florida Everglades. A good many find that their investment of their hard-earned money is in land that is under water. The syndicate promises to have the water off in due time so the land can be used for farming and agriculture. May be they will get the water off, and may be they won't. Many people also write me and ask if they can get employment down here to spend their winters. When you look about you, you see certain people who *always* have something to do, and also other people who seem to be depending on somebody to get a job for them. If you have trouble in getting something to do up North or anywhere else, I think very likely you will have trouble here. If you always have more work ahead of you than you can possibly take care of, you will find it will be a good deal the same down here. *Capable* men are wanted everywhere; but men who are always having bad luck don't seem to be wanted *here* or anywhere. Here in Bradentown, where there has been so much building going on during the past winter, there has been an unfilled call for skilled carpenters. A young carpenter from Indiana happened to pass by my place one day and stopped to talk a little. He said he had been here only six weeks, and had earned enough at carpentering to send home \$100 already. In conclusion, if you want to know about these things you *must* come down here; and, once more, don't *think* of investing money until you see what you are buying.

POULTRY DEPARTMENT

A. I. Root

TWO EGGS IN ONE DAY FROM ONE DUCK, ETC.

This has happened three or more times during the winter; and I would have said more about it had it not been for the fact that this same duck averaged only one egg a day. As is well known, the Indian Runner ducks usually lay their eggs about daylight, sometimes a little before. Well, for months past I have been getting three eggs a day from three ducks. One of the three, however, instead of laying with the others as usual, very early in the morning, at three different times, and perhaps more, instead of laying in the morning she dropped a very soft-shelled egg about dusk the night before. This made four eggs from three ducks during daylight of a single day; but on every occasion she laid no egg the next morning. Now, these eggs that were dropped prematurely the night before were all soft-shelled—so soft that, if they did not break when resting on the ground, they would break unless very carefully handled. From this I infer that it takes twelve hours or more for a duck to complete the shell so that it will be hard enough and firm enough to be han-

dled. As the ducks were spending their time during the day in the canal, and there was an abundance of shells in the same canal, I thought it could not be that they lacked lime; but after I gave them a dish of crushed oyster shell, and also another dish of mica crystal grit, no more eggs were dropped the night before.

From the above I am inclined to think that most if not all the records of hens that have laid two eggs in a day were like the above. One egg is laid very early in the morning, and the other in the afternoon or at night. Some time ago my brother wrote about finding eggs under the roosts. The roost was so low down that the eggs as they dropped into the soft dry sand were seldom broken. But my experience has been that these eggs dropped in the night or very early in the morning are mostly soft-shelled. Many of them are broken when picked up. During several past winters I have found more or less eggs under the roosts in the morning; but for some reason which I can not explain, during this winter scarcely an egg has been dropped in the night in this locality. Perhaps it is because of late our

hens have been better supplied with crushed shell and grit than ever before. Soft-shell eggs are to be avoided as far as possible, because it is almost sure to get the hens into the habit of eating their eggs.

DUCK-HOUSES, DUCK-BROODERS, ETC.

Heretofore when my growing ducks got so large as to crowd their brooder, we have been in the habit of changing them to a larger-sized house or coop. Now, changing chickens or ducks from the home that they are accustomed to, to a different one, is always a bad plan. This has been frequently talked about in the poultry journals. In a recent *American Poultry Advocate* a lady advised giving ducks more room when the weather becomes warm, by attaching a dooryard made of poultry netting. This covered dooryard would permit them to go outdoors or inside according to the weather to suit themselves. Just now (April 10) we are having warm weather down here in Florida; and I notice that, when I try to get my ducks to go in at night, they greatly prefer sitting around in front of the door. I have learned by sad experience, however, there is no safety for ducks here until half grown or more *unless* they are securely fenced in by wire cloth or otherwise during the night time; and, in fact, I lost one duck during a moonlight night when it was fully eight weeks old. I don't know what became of it unless it was taken by the midnight owls. Since then I have had them securely "fenced in" by wire cloth every night, and no more have been lost. The same is true of our chickens, both little and big. At dark I shut them all in their enclosure, and let them out again by daylight next morning.

A SCREENED "PIAZZA" FOR THE GROWING DUCKS AND CHICKENS.

This afternoon I have just added a covered wire-cloth dooryard, just like a front porch or piazza for people. Since I have seen how nice it works I am sorry that I did not have this dooryard enclosure for my little ducks whenever the weather was so warm that they *prefer* to be outdoors instead of inside. When first taken out of the incubator I have several times given them to a sitting hen, giving a hen as many as twenty or thirty. Now, I notice that very soon the little ducks begin to prefer to sit down *beside* the hen instead of getting under her wing, especially when the weather is very warm. I feel sure that the best and proper way is to let the ducklings have their choice. Whenever they want to be outdoors, right under the stars, give them the privilege. This wire-cloth enclosure is made right over the front door where they are accustomed to go in. There is no difficulty at all in getting them to go in at night; whereas if you try to drive them in, especially when it is warm, and they are crowded inside, you will hear them uttering strong protests about being cooped up when they want to be outdoors. I tell you a flock of twenty-five Indian Runner ducks *can* make a protest if things are not to their liking.

The clipping below tells where I got my idea of "front porch" all of poultry netting:

We had coops in which to keep the hens and ducklings, but the babies soon grew too independent for their mothers. They flock together in a very few days, and for this reason ducklings of different ages should be penned separately. They dislike roosting in coops, but will readily go into a pen and roost on the dry litter which should always be kept for them to rest upon, at least until settled warm weather comes. As damp roosting quarters are very bad for them, keep a part of their sleeping quarters roofed over.

DANDELIONS AS A GREEN FOOD FOR POULTRY.

On page 637, Oct. 15, 1911, I spoke about a flock of Wyandottes picking out every bit of dandelion leaf in the orchard where it was grown. Well, just now dandelions are starting up in wonderful profusion almost everywhere. Our orchard of about a hundred trees is divided into three poultry-yards—a fence down through the middle, and then a fence dividing one of the halves of the orchard. A flock of about 25 Rhode Island Reds, and three-fourths or perhaps half as many White Wyandottes, have a fourth of the orchard. While the Rhode Island Reds do not seem to be able to pasture down the dandelions they have access to, the White Wyandottes snatch up every leaf about as soon as it comes in sight. Now the Wyandottes may have a special liking for dandelions, or perhaps they have an "acquired appetite." At any rate, it seems to be the very cheapest way of giving them green food, and they certainly are a healthy lot, and are giving a fine yield of eggs. By the way, I notice in the *Inland Poultry Journal* among their short items the following:

Best poultry tonic on earth is God's tonic—the common dandelion fed freely.

Just now I clip from the *Cleveland Plain Dealer* the following:

In the feeding of ducklings, dry grain is unsuitable. They will not eat enough sharp grit to digest it. Whole wheat and cracked corn, boiled together and let stand until cold, will give good results. But they should not be confined to this alone. They should not be fed upon highly concentrated food, because they will not thrive upon it. Some people will feed their ducklings a regular cornmeal ration, with beefmeal or something similar added, and then wonder why they can not raise ducks. Meat nor ground bone should not be given to ducklings while they are small. Cornmeal should always be mixed with something lighter, such as bran or vegetables, either cooked or raw.

Ducks are very fond of dandelions chopped and mixed with ground grain. Raw cabbage, green yre, and clover are also liked. When potatoes are used, they should be boiled, then mashed, and mixed with equal parts of bran and cornmeal. If the bran and cornmeal are well moistened before being mixed with the potatoes, the mixture will be less gummy than it would be if dry meal were used. A duck can not eat sticky feed.

Never let feed become soured or fermented. It should be fresh and wholesome. Fermented food will cause convulsions in young ducks. Therefore in warm weather feed mixtures should not be allowed to stand even from one meal to another.

Now, if you are inclined to call dandelions a pest on your premises, just try feeding them to the cow, as I have spoken of several times before. If you have no cow, you certainly can afford a few chickens;

and after they learn the trick, dandelions will get to be a great part of their diet.

EGG-TESTERS—SOMETHING NEW IN THE LINE.

In my hand is a circular describing a new invention for testing eggs. A whole trayful of eggs is taken out of the incubator and set over a box containing several tungsten electric globes. The strong light from these lamps coming up through the wire bottom of a tray of eggs illuminates them sufficiently so the unfertile eggs may be picked out from the fertile ones without handling the eggs separately at all. Now, this reminds me of something that I have neglected to mention before. A little over a year ago I sold my Buckeye incubator to a lady in Florida, who lived next door. When I asked her about testing, she informed me that she tested the whole trayful at once by setting them on the carpet before a small south window. The strong light of our Florida sun came through an otherwise darkened room, and struck that tray of eggs and illuminated them sufficiently so the fertile germs were all plainly visible on the fourth or fifth day without handling the eggs. I have never tested a trayful in that way; but I have accidentally laid eggs down in a ray of sunlight, where the fertile germ was plainly visible. But I must confess there is something about it I do not fully understand. You must have your eye in a certain position regarding the sunlight, and your eye must be in the shade. Several times in handling eggs from sitting hens, say after they have been incubated about a week, I by chance brought them into a ray of sunlight while the egg was in my hand, so that the spiderlike blood-veins were plainly visible. At the present time I am not using an incubator; but I ask the friends who are doing so to experiment a little and report, and see if it is not possible to test eggs by the trayful without handling them singly. Our friends who are hatching chickens by the thousand would find such an arrangement a great help. The Reflex egg-tester is furnished by the Eureka Mfg. Co., Pekin, Ill. It is made to be operated by electricity, or by lamplight where a current can not be obtained.

The circular referred to above threatened infringers who presumed to make use of his invention without buying a machine. Now, from the clipping below, from Green's *Fruit Grower*, it would appear that it is by no means a new discovery after all. I am sure that any poultryman is at perfect liberty to use such a machine if he chooses.

A million eggs a day are received at New York, and all must be tested. The eggs are unloaded from a big case into a machine tester and passed along in front of the operator who sits opposite a reflector. The only light that reaches this reflector must go through the eggs. They are then passed on by an automatic tray. By this machine 72,000 eggs have been tested in 4½ hours. By the old method it would have taken a week or more to do the same work. Several of these machines are in use on Market Street in this city for candling the eggs each day as they come from Kansas.

THE VOCABULARY OF THE POULTRY-YARD; OR, THE LANGUAGE OF FOWLS.

If you don't take it already, be sure to send five cents for the April number of the *American Poultry Journal* (Chicago); or, better still, send fifty cents for a whole year; for the opening article from our old friend H. H. Stoddard is well worth the price to any one who loves chickens and is anxious to understand their talk. Friend S. describes their language so far as to indicate 43 different words or expressions, and I can indorse the greater part of them, and I would add at least one more. When you catch a chick that is partly tamed it utters a most plaintive, pleasing note, half way between fright and half alarm. It is such a pleasing (or pleading) babyish appeal that I almost always restore it to the flock again. It seems to say in words, "Oh! please, please let me go; don't you notice how my little heart is beating with fright?" and when set down, there is the prettiest note of gratitude and thanks.

A few days ago I gave 28 chicks, right from the incubator, to a Leghorn hen that had been only one night on a nest of eggs. She looked at the bright little family for quite a while, apparently undecided, but finally ventured just one brief little note, almost under her breath. Let us pause a moment right here, I might almost say "with uncovered heads," as in the presence of the great Ruler of this stupendous universe.

These chicks never saw a mother hen until this moment, and it is not at all certain *she* ever saw a chick before. Notwithstanding, from that wonderful instinct in her makeup, she uttered a low brief "pass-word." In a second every one of the 28 comprehended the language that was a part of their very makeup *inside the eggshell*, and every chick of the 28 gave a quick and prompt answer. Just then I laughed out loud ("right in *school*"); and she, becoming frightened, uttered another word of warning and alarm; and every "mother's son" dropped in their tracks as if dead. At first I couldn't understand it until I recalled seeing a mother partridge in the woods of northern Michigan do the same trick. The young partridges were so much the color of the brown leaves in which they hid that you could hardly decide, as they lay still as death, that they were *not* leaves. In fact, these young buttercups looked almost exactly like the baby partridges. There they lay or skulked in the grass until she decided the danger was past, and gave a *third* command to "follow her lead." Since then she has been a model queen, and her 28 a set of most obedient and loyal subjects. They are now two weeks old, and every chick is as bright and lively as a cricket.

One more suggestion in closing. Please consider that this language has been the same for centuries, possibly; and as it seems to be the one particular language used by all the domestic fowls, from the bantam to

the great Brahma, does it not indicate that they all came originally from one common stock? Now, I know the partridges have a similar code or language for their young; but I am not sufficiently acquainted with turkeys to know whether they use the same

or a different system. From my acquaintance with the Indian Runner duck I feel sure their method of communication is different, but it is a good deal along the same line. I am going to make further investigations. Will you help me?

HIGH-PRESSURE GARDENING

A. I. Root

SWEET CLOVER AND OUR DEPARTMENT OF AGRICULTURE.

I am very glad indeed to note that our Department of Agriculture has not only seen fit to recognize, but has put out a bulletin, No. 485, dated March 12, 1912, in regard to sweet clover. It has straightened out and given us so much correct information in regard to the many eccentricities of sweet clover that, as I go over its pages, I feel as if I should like to quote from every one of them; and I hope that every one of you who have been interested, and have had opinions either for or against sweet clover in the past, will send for this valuable bulletin. Years ago Dr. Miller said it was beyond his comprehension that sweet clover should grow where and when he did not expect it nor want it, when it would almost *refuse* to grow on nicely prepared soil, and this bulletin tells us why. I extract below from page 12:

It also makes an excellent growth in gravel-pits and stone-quarries, but for some reason does not seem to do well on unsettled cultivated soil. It makes its best growth where the soil is compact, and not crowded with other vegetation.

See also below:

REQUIREMENTS FOR OBTAINING A STAND OF SWEET CLOVER.

A great many farmers have noted the luxuriant growth of sweet clover along roadsides and in other uncultivated places where it grows without any special attention, but have often been disappointed by obtaining a very inferior stand when seeding it upon cultivated land. For this reason it is necessary to look rather closely into the requirements for obtaining and maintaining a successful stand of this crop.

Also the following:

SOILS ADAPTED TO SWEET CLOVER.

Almost any reasonably well-drained soil will grow sweet clover. It is more tolerant of poor drainage, overflow, and seepage conditions than alfalfa or red clover. In irrigated sections, especially where the reservoir system is in use, large bodies of land are apt to become useless for ordinary crops on account of the rising of the water-table in the fields near by. On such areas sweet clover has been observed to make a very vigorous growth.

On page 15 a reason is given for this queer behavior as follows:

PREPARATION OF A SEED-BED FOR SWEET CLOVER.

Sweet clover requires a thoroughly compacted seed-bed with just enough loose soil on top to enable the seed to be covered. The lack of a solid seed-bed is probably the chief reason why sweet clover so often fails when seeded upon *cultivated* fields. The success of the crop on poor hills from which practically all the soil has been removed by erosion, and on newly exposed clay areas where the ground is extremely hard and compact, is thus explained. One field in northern Virginia, sown on a loose seed-bed, heaved out almost completely in the spring of 1911. When a field which has been in cultivation is to be seeded to sweet clover it

should be more thoroughly firmed and better settled than if intended for other crops. Plowing, if necessary, should be done several months before seeding; but it is usually best to seed on ground such as corn stubble that does not require plowing, and depend on a disk, a turning and slicing harrow, or a spike-tooth harrow to cover the seed.

FERTILIZERS FOR SWEET CLOVER.

It is not usually necessary to apply any sort of fertilizer to the ground upon which sweet clover is to be seeded. Its success on the limestone hills, in stone-quarries, etc., would seem to indicate the need of lime in the soil. Its successful growth, however, on soils that undoubtedly are deficient in lime shows that liming may not always be necessary. Sweet clover will probably respond favorably to the regular commercial fertilizers; but owing to the ability of this crop to succeed on many poor soils, especially those of limestone origin, it is probably the better practice to hold the fertilizer and apply it to the cultivated or money crops which follow the sweet clover. No information concerning the use of fertilizers on sweet clover in this country is available.

From the above quotations you will notice that sweet clover as a rule does not seem to be suited to a loose friable soil, such as other crops and other clovers require. Below is a clipping I just found in the *National Stockman and Farmer*:

From time to time I have read in the agricultural press articles on sweet clover. I will give my experience. In 1910 I sowed 15 pounds of the white variety to the acre on a seven-acre field that had been fall plowed and was limed in 1909, and was given a heavy coat of manure in 1908. It was harrowed several times until about the 25th of May, when the seed was sown, and covered with a spike-tooth harrow. Rain came in a few days, and the season was a fair growing one for grass. Well, about one tenth of the seed started; but the plants were small, and all died before winter; but where the seed fell around the edge of the field, and in fence corners, the sweet clover fairly outdid itself. Some of the plants grew four or five feet high. In 1911 a neighbor sowed 12 pounds of buckwheat, and used fertilizer. The sweet clover seemed to all start, and at harvest was half as high as the buckwheat; but after the grain was cut the sweet-clover roots all seemed to die, and before winter were all gone.

Schuyler Co. N., Y.

STEPHEN KELLOGG.

You will see by the above that it did not seem suited at all to the soil prepared for other crops; but when the seed lodged in the hard soil over in the fence-corners it was all right, and made an astonishing growth in a very short time. On our Medina clay soil we have much trouble in winter from plants being thrown out by the frost. Strawberries especially, unless heavily mulched, are likely to be clear up on top of the ground before freezing and thawing is finally over. Some years ago a visitor, an expert strawberry-grower, was going through our grounds in the fall when the boys were hoeing out the plants that had got over into the paths on hard ground where there had been much tramping. He suggested to me that the

plants over in that hard ground would winter all right without being thrown out by the frost; and as I was very much troubled on that ground in that way, I let those struggling plants in the paths remain. It was just as he said. They wintered all right, and were not disturbed by the frost at all. Of course, mulching is a remedy for this trouble, but the strawberry-beds do not always get it. I believe successful wheat-growers have found that packing the ground by repeated rollings in order to make a very firm and hard seed-bed has a similar result; and I think that somewhere in this bulletin there is a suggestion that sweet clover must have hard ground in which to push its roots, in order to crowd that vigorous tap-root away down into the soil two or three feet. To penetrate the hard impervious subsoil there has got to be some powerful pushing, and the plant can not do this unless it has a good firm solid foothold. Do you get the idea?

FAILURE OF THE SEEDS TO GERMINATE.

For twenty or thirty years past, during which we have sold sweet-clover seed, there have been complaints that it did not come up at all, or else only a small part of the seed germinated. And we have found out, also, that, like basswood seed for instance, what did not come up one year might come the next, and so on to the third year or even later. Well, on page 16 there is a remedy besides the well-known one of freezing and thawing during winter and spring. Read the following:

SEEDING SWEET CLOVER.

It usually requires 20 to 30 lbs. of hulled seed and at least 5 lbs. more of unhulled seed per acre. A lesser weight of seed would be sufficient were it not for the fact that often one-half of the seed has such hard seed-coats that it does not germinate the first season, and therefore is practically useless. This retarded germination of the hard seed can be overcome by soaking the seed in commercial concentrated sulphuric acid for half an hour. It should then be quickly washed, using running water if possible, as sulphuric acid becomes very hot when mixed with a small proportion of water. A great deal of water is therefore necessary in order to lessen the danger of burning. The seed should then be dried off quickly by spreading it out on a floor or canvas, and stirring at intervals. The acid corrodes or eats away the hard impermeable seed-coat sufficiently to enable the seed to absorb enough moisture to germinate. This method has been investigated by Prof. H. L. Bolley, of the North Dakota Agricultural Experiment Station, and by Dr. H. H. Love and C. E. Leighty, of the New York (Cornell) Experiment Station. Tests made in the Department of Agriculture gave an increase in germination of 40 to 45 per cent. Great care must be exercised when working with sulphuric acid, as it burns the flesh and any wooden objects badly, and is especially dangerous to have around in the presence of children. The vessels used for treating the seed should be of earthen or enameled ware to prevent corrosion by the acid. After the seed is treated it should preferably be sown promptly, as it has a tendency to dry out after the coat has been eaten off by the acid, but it can be held for two weeks or a month under favorable conditions without any considerable deterioration.

FERTILIZERS FOR SWEET CLOVER.

As a rule, sweet clover does seem to do better on ground where nothing else will grow—such ground as is thrown out in making canals or deep railway cuts, for instance;

but I have *occasionally* seen tremendous growths of sweet clover on ground made very rich with old well-rotted stable manure.

SWEET CLOVER FOR FEED; THE REASON WHY SOME HORSES AND CATTLE REFUSE TO EAT IT.

I was once riding with a beekeeper in Michigan. He said they had sweet clover all around them, but his horses and cattle would not touch it. While we were talking, and the team was naturally moving at a slow pace, all at once his two horses began cropping right and left at the sweet clover that grew by the roadside. Of course we had a big laugh. But he tried to explain it by saying they had a fashion of cropping at any weed or tree, especially when it was near their dinnertime. I do not remember just now, but I think this friend discovered later that his horses and cattle *would* eat sweet clover.

Preliminary experiments with leguminous crops, even at the hands of careful experimenters, can not always be taken as final. In this connection it may be mentioned that, when cowpeas were first tried in portions of this country, it was found so difficult at first to induce stock to eat the vines, either when cured or made into ensilage, that even at a certain State experiment station the opinion was expressed that cowpeas were of no local value as feed for live stock. Subsequent developments proved that this crop has great possibilities, even in the sections where the preliminary trials showed it to be very unpromising as a feed owing to the difficulty experienced in making stock eat the forage.

Much greater difficulty is usually experienced in inducing the stock to become accustomed to sweet clover than is the case with other legumes; but the fact that in at least half of the States in the Union stock have become accustomed to eat this plant indicates that the natural distaste which stock at first show can be successfully overcome.

SWEET CLOVER AND ITS VALUE TO CROPS THAT FOLLOW IT.

At the Ohio Experiment Station sweet-clover land gave a yield of 26.9 bushels of corn, as compared with 18.6 bushels on similar land not in sweet clover the previous year. An experiment performed at Tost, Germany, showed that sweet clover preceding oats increased the yield of oats 17 bushels per acre. Part of the field was devoted to potatoes, with the result that the yield was more than doubled when compared with an adjoining plot not previously seeded to sweet clover. Some idea as to the large amount of green material which sweet clover provides for soil improvement is shown by a report from the Ontario Experiment Station in the cutting of over 30 tons of green fodder per acre, as compared with 13½ tons of mammoth clover, which stood next in rank.

Its large roots, which develop the first year, facilitate drainage and do much to break up and improve the tilth of the soils which lie below the reach of the plow, as these roots rapidly decay when the plant dies, and their effect is therefore almost immediate.

In our book on sweet clover I tell about getting a fair crop of very nice potatoes on hard unpromising clay and gravel, thrown out of a deep railway cut, by plowing under a dense crop of sweet clover when it was about a foot high.

The above are only glimpses of the valuable points of the bulletin.

It is fully illustrated with some beautiful pictures of sweet clover and crops that have been grown afterward.

Address the Department of Agriculture, Washington, D. C., calling for Bulletin 485.

LOSS OF 600 COLONIES OF BEES BY SMELTER GAS.

WE have heard that there has been a loss of 600 colonies of bees within a radius of three or four miles of a silver-smelter located at Smithville, Ontario, Canada. There is some talk of bringing an action against the smelter company; but whether any thing of this kind will be done or not we are not advised.

OUR COVER PICTURE.

THE front cover of this issue represents a characteristic piece of raspberry bee pasturage in Northern Michigan. The photo was made by the late W. Z. Hutchinson. Raspberries do best away from cultivated land in territory that has been lumbered over, with a growth of small trees just high enough to shade the bushes. Such pasturage unfortunately is not permanent, because, as the trees grow taller, they choke out the bushes, and the first forest fire cleans them out entirely. For that reason, two years ago many beekeepers had to move their apiaries from the raspberry to other territory that had not been devastated by forest fires.

Raspberry honey, by the way, is regarded as one of the finest honeys in the world. Mr. W. Z. Hutchinson had no trouble in selling all he could produce of it at two or three cents above the market price.

BEES FOR SALE

IN view of the severe winter losses, and with a desire to help out those who wish to make a start again, we promised to give a list of those who have bees for sale. The following have sent in their names:

Geo. E. Smith, Hampstead, Md.; S. W. Taylor, Shickshinny, Pa.; H. E. Zech, Seven Valleys, Pa.; J. I. Elliot, Punxsutawney, Pa.; G. W. Strangways, Creek Bank, Ont.; R. J. Smith, Ticonderoga, N. Y.; J. H. Manchester, Preble, N. Y.; S. J. Alexander, Fisher, Ark.; Mrs. Almida Ellis, Fremont, Mo.; Frederick, Ill.; T. E. Hudson, Norfolk, Va.; Vern O. Derby, Wileyville, West Va.

The only caution we wish to enter is that the purchaser make sure that the bees are free from disease of any sort, and that he give instructions to have the hives before shipping screened at the top and bottom. No very strong colony should be sent by rail. The extra-strong ones should be divided and put into separate hives. Frames should be securely fastened, and combs, if

not wired, should be well attached to the top-bar and end-bars at least.

Those in need of bees would do well to write to the parties named; and do not forget that the express on small lots will be one and one half times the ordinary rate.

TROUBLE IN CALIFORNIA.

JUST as we go to press, information comes to us that Prof. A. J. Cook, State Horticultural Commissioner of California, is being severely censured by the fruit-growers because he summarily removed Chief Deputy Quarantine Officer Brenner, who has charge of keeping fruit pests from being imported into California.

And there seems to be also some trouble over car load shipments of bees from Utah and Nevada into California, on the ground that they would be overloading territory that is already overstocked, and of the danger of bringing bee disease. At this writing we have insufficient data upon which to base any judgment as to the merits of either case. Our California editor, Mr. P. C. Chadwick, will doubtless have something to say on the matter later on.

A REMARKABLY SUCCESSFUL SHIPMENT OF 500 THREE-FRAME NUCLEI FROM FLORIDA TO OHIO.

WE sent our apiarist, Mr. J. E. Marchant, early this spring down to his father's, in Sumatra, Fla., after a carload of bees. We had previously shipped down 500 three-frame nucleus hives in the flat. These were nailed up and filled with bees, and started northward May 6, arriving here on the 13th in splendid order in spite of the extremely hot weather at the time of starting, and very cold and rainy weather, ending in a snowstorm, just before they arrived at Medina. So successful was the shipment that Mr. Marchant has been sent down for another carload, and we expect him to arrive at Medina on the 3d of June. Full details, with illustrations, will be given in our next issue. In the mean time we feel that we have a fine lot of Italian bees from the territory where foul brood was never known to exist. In fact, so far as we know there is no foul brood—either European or American—in all Florida at the present time. Years ago a little was known on the east coast; but in the Appalachian region of

Northwest Florida foul brood has never been known.

The first car of bees arrived in time to catch the fruit-bloom flow, and a second shipment will arrive in ample time to catch clover and basswood. The bees did not leave Florida until they had gone through the heaviest of the tupelo flow. We are, therefore, making the same bees do service through two honey-flows.

MORE BEES KILLED FROM SPRAYING FRUIT TREES WHILE IN BLOOM.

EVERY year we get more or less of complaints about the time fruit trees are in bloom, showing losses of adult bees while the trees are being sprayed. The following is another sample of some of the letters we get:

Can any thing at all be done to secure legislation in Ohio relative to the spraying of fruit trees? The seriousness of the condition demands that some very stringent action be taken at once by beekeepers, and all interested in that pursuit, if beekeeping is ever again to be profitable in this State. A customer at Etna, Licking County, Ohio, writes me that he has lost ten hives of bees on account of spraying done by his neighbors. This is but one of many complaints of this kind. It seems that, in spite of all the information on this subject circulated by Government bulletins and agricultural and apicultural publications, a large proportion of the fruit-growers persist in doing their spraying while the trees are in full bloom. Is it ignorance or sheer devilishness? I am inclined to think it is a little of both.

If the weather for the last month or six weeks has been as favorable elsewhere as it has been in this immediate vicinity, the amount of spring dwindling ought not to be excessive, and I am inclined to believe that not a few of the cases of dwindling reported can be traced to this spraying nuisance.

Surely the apiarian interests of this State, if combined, are powerful enough to secure legislation that will afford some relief from a condition that is becoming intolerable.

Zanesville, O., May 17.

E. W. PEIRCE.

Now, we don't know whether an anti-spraying law could be secured in Ohio or not. One is in force in Michigan and in New York, and, if we are correct, two or three States in the West have similar legislation. Some believe (and they are men whose opinions are worth considering) that these losses are due rather to the presence of bee disease than to the spraying liquids. We hardly share this view, for the reason that these complaints come regularly just about the time that the trees are in bloom. As the bees are found dead in front of the entrances of the hives, and as foul brood and European foul brood attack only the larvæ, or bees in the brood stage, we can not get away from the belief that the bees die because they are sprayed at the wrong time. We should be pleased to get further reports.

A POSSIBLE LOOPHOLE IN THE RECENT POSTOFFICE RULING RESPECTING THE MAILING OF QUEEN BEES.

DOOLITTLE & CLARK draw our attention to the fact that the postal ruling concerning the mailing of queen bees, and given on page 292 of our last issue, does not make it obligatory on the part of the breeder to

boil the honey he uses in his queen-cage candy providing he can furnish a copy of a certificate to the effect that his apiary from which queens were taken was duly inspected by a State inspector, and found to be free from disease. It would thus be possible for a careless queen-breeder whose queen-rearing apiary has been inspected, to buy honey of unknown source, make queen-cage candy of it without previous boiling, and still keep within the postal ruling. Evidently here would be a loophole by which the disease could be carried in queen-cage candy. Messrs. Doolittle & Clark take the view (and we share the same opinion), that the Postoffice Department, in making this alternative ruling, had in mind those queen-breeders who would not be able to secure the services of a State or Government inspector except at a prohibitive price, that it made the alternative ruling so that such breeder could continue to send out queens, providing he boiled the honey which he used in making queen-cage candy. While technically it might be possible to send bee disease and not violate the ruling, yet we believe that all right-minded queen-breeders who are desirous of fostering and protecting the very industry from which they derive their own bread and butter will comply, wherever possible, with both regulations—that is to say, they will send out a copy of a certificate from their State inspector showing that their apiary has been inspected, and found free of disease, and likewise a statement that the honey used in making their queen-cage candy has been boiled. We are doing this with all queens we send out. All honest breeders we feel sure will unite in supporting our Postoffice Department in making such regulations as will prevent the spread of bee diseases through the mails; and yet no one of us desires to remove any competitor when, by reason of his locality, he is unable to secure the services of an inspector.

BABY NUCLEI FOR QUEEN REARING BEING ABANDONED AT MEDINA; QUEEN REARING SIMPLIFIED FOR THE HONEY PRODUCER.

A NUMBER of years ago the general plan for mating queens was to use one and two frame nuclei, using standard-sized frames. Later on, the late E. L. Pratt, of Swarthmore, Pa., claimed he made a success of using baby nuclei containing only from 100 to 200 bees in miniature frames. This same idea had been tried out before Mr. Pratt's time, but abandoned as being impracticable, for the simple reason that these "babies" would swarm out on the least provocation—very often when young queens went out to mate. But Mr. Pratt proved that these "babies" could be made to mate queens. We demonstrated that we *could* do it also, but finally concluded that the 100 or 200 bee baby nuclei were too small. Later on we adopted larger "babies" that contained something like 1000 bees, and two frames that would have the combined area of two-

thirds of a standard Langstroth frame. These nuclei worked much better—that is to say, they are more dependable. But even *they* showed a considerable tendency to deport themselves unseemly, much after the manner of their smaller prototypes.

During the last year or so we have been trying the full-sized two and three frame nuclei, and also the larger “babies.” While the small nuclei, we thought, would mate the queens more cheaply than nuclei using standard frames, yet the latter, because of their greater reliability, and because they can be developed into colonies of bees, will, in the end, produce queens more cheaply than or as cheap as the unreliable “babies.”

We can illustrate it more specifically by putting it this way: Suppose a “baby” will mate a queen for 25 cents, and a full-sized standard nucleus for 40 cents. At the end of the season, the full-size-frame nuclei will be fair colonies, or in shape to unite with full colonies, while the “babies” are practically good for nothing. The frames will not fit any thing, and the small bunches of bees growing smaller and smaller as the season advances are not worth fussing with. The veteran queen-breeder, the late Henry Alley, who used large-sized baby nuclei for many years, made it a practice at the close of the season to shake the bees all off the frames of his “babies” on to the ground. While they *could* be put together in one lot, such a heterogeneous mass of bees, he claimed, would never make a decent colony to winter.

And he was right. This queen-rearing proposition may not be interesting to a certain class of *honey*-producers except in this way: It will convince them that, with very little trouble on their part, they can make up queen-mating nuclei; and when they have all the queens they need for their own purpose they can unite these nuclei back into colonies, especially if they take these nuclei from an outyard and bring them to a home yard where they do their uniting. It takes a great deal of skill and fussing to make the “babies” behave themselves as babies should, and the average honey producer has neither the time nor the skill to make them “behave.”

ADVERTISING FIVE-BANDED BEES.

On page 126, March 1, we made the statement that we did not believe there were a dozen colonies showing *all* five-banded bees in all the United States. On previous occasions we have protested against the advertising that *claimed* to furnish five-banded bees, and *actually* furnishing three and four banded ones instead.

Mr. Geo. M. Steele, of Philadelphia, challenged our statement on page 126, that there were not a dozen colonies showing *all* five-banded bees. He said he had sixty colonies that would go one better than five bands in 95 per cent of the workers, and that he had some five colonies that would run gold to the tip in 100 per cent of the workers.

Two years ago a representative of ours called upon Mr. Steele, and found that he had very fine yellow stock, and hoped that, when a favorable opportunity came, we would editorially make mention of the fact. This we did in our April 15th issue. Since that time two of Mr. Steele's customers have come back at us, saying that the stock they had received did not come anywhere near the standard claimed. We referred this matter to our representative, who called upon Mr. Steele again last summer, and found that the bees, at the time of his visit, were not up to the former standard; but at the time we wrote the statement on page 126 we were not aware of his second visit.

It appears that Mr. Steele had been having an extraordinary run of orders for queens, and used up all his extra-yellow stock, and in endeavoring to fill his orders he had used other yellow stock, which apparently was not equal to his own original yellow blood. Mr. Steele has just written that he will make the matter good, and we have no doubt that he will, but it is due our subscribers to state the facts as they are.

In the meantime we still insist that advertisers of yellow bees should be very careful about making statements concerning their stocks. If they run out of the special grade of queens advertised, and have to secure other stock, they should notify their customers of the fact. When a breeder offers to furnish yellow-to-the-tip or five-banded bees, he should furnish precisely that stock. If unable to do so he should charge less or return the money. In our judgment it is a great deal better to advertise extra-yellow or four and five banded stock; then if the breeder is able to furnish better—that is to say, yellow all over, or strictly five-banded bees throughout, his customer is more than pleased, and in all probability he will send a duplicate order for more bees and queens. In most if not all cases, those who have advertised the five-banded stock have been perfectly willing to send additional queens that will meet the standard; but that does not avoid complaints in the first place, nor does it release us of our embarrassment in adjusting these differences.

In the meantime we have heard from several other advertisers of five-banded stock, claiming they have stock that will run *all* five-banded. While we do not question their word, we want *proof* that will be satisfactory to our *readers* who are beginning to doubt whether there are any queens that will furnish *all* five-banded.

Later.—Mr. Steele guarantees to prove that his “breeding queens will and do produce 95 per cent over four-banded bees,” and that his “drone mothers will produce drones, 99 per cent of which will be golden to the tip. This is a considerable recession from the first statement, where he said he had “60 colonies that would go one better than five bands in 95 per cent of the workers.” This we interpreted to mean that they would be *six-banded*, while now the guarantee is for 95 per cent over *four-banded* bees only,

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

BOTTOM STARTERS $\frac{1}{4}$ inch deep in sections are advised, *Australasian Beekeeper*, p. 85, and I've seen the same thing elsewhere. The bottom-starter was born "in this locality," and many years of experience have approved $\frac{3}{8}$ as a proper depth for thin foundation. For extra thin, $\frac{1}{2}$ would likely be better; but when too shallow the bees are likely to gnaw it down.

J. E. CRANE, p. 295, I think that "mixture of honey being darker than either kind separate" meant when mixed by bees. I don't know whether that would be different from your mixing or not. Moreover, I can imagine that a mixture of two shades nearly alike might be darker than either, while a mixture of very light and very dark would be lighter than the dark.

THE BEES needed feeding, and the whole family was on the sick list. So I took the laziest plan possible. I set a tub in a sunny place, dumped in sugar and water, stirred it up, and threw in some cork chips. Worked perfectly. It was open to neighboring bees, but I could afford that for the saving in labor. Of course the strongest colonies got the lion's share, but it was easy to take frames from them and give to others. [This is a good scheme; but you do not say how much sugar you used to the water. While that is not, perhaps, so very important, yet the beginner will wish to know. Ordinarily we think it is well to make any sugar mixture for outdoor feeding very weak. Anywhere from six to ten parts of water to one of sugar is about right.—ED.]

THE TITANIC disaster has caused much comment, and there is clamor that something should be done about it. That's because it's unusual. If it occurred weekly some people would say it is all right. "How do I know?" Please tell me what is the weekly loss of life from drink as compared with the Titanic loss. [Just so. One Titanic disaster caused by an iceberg creates commotion throughout the world. As you say, there are Titanic disasters occurring every week from drink; but we are so accustomed to them that they fail to stir us up. But the world does move, and Titanic disasters due to liquor will (in another generation at least) be a thing of the past. The liquor people are beginning to see the handwriting on the wall already.—ED.]

MR. EDITOR, that's a good comparison of square beeway and 4 x 5 plain sections, page 315, but in a few points some would disagree. You don't mention that the tall section tips over easily. The plain surface makes it easier to scrape, but the greater care required in handling overbalances that, so that on the whole it is harder to clean than a beeway section. It takes less room in a case, but one large dealer says that's

against it, for the smaller case looks of less value, and the grocer goes for the bigger case. "Any article of food looks better. . . that is taller than broad." For instance, a cookie, pie, or orange. The important place for the looks of a section is on the plate. On a square or round plate the square section looks better; on an oblong plate, the tall section. Are honey-plates mostly oblong? "There is no excuse for a clerk punching his fingers into either section." Does that in the least change the fact that clerks do punch plain more than beeway? [The statement that "any article of food looks better that is taller than broad" refers to packages and not to the article itself. Orange-boxes are oblong. Packages holding cookies, such as are put out by the National Biscuit Co., are taller than broad. A section holding comb honey is a package. When that section is put into a carton the shape of the carton is more in conformity with other packages of food stuffs.—ED.]

LOUIS SCHOLL, you're just right as to the importance of good tags for hive-numbers; and if you can wake up manufacturers to the importance of listing them you'll deserve well of your fellows. I've been on the hunt for years. If I found any thing good, the price was prohibitory. The Root Co. printed some on heavy manilla, but they don't last. Aluminum tags are advertised in German journals. I sent money for a sample, but never heard from it. Until you can buy them, you can make them like mine, which are entirely satisfactory, and good for 25 years or more. Cut tin 4 x 2 $\frac{1}{2}$ inches. Paint one side white, and then put on black figures 2 inches high. Fasten on hive with a single one-inch wire nail at the upper end, driving the nail in one-third length, so it can be easily drawn out with claw-hammer.

If they can find nothing better, I suggest the following for manufacturers: A metal tag 2 $\frac{1}{2}$ x 1 $\frac{1}{2}$ (possibly less than 1 $\frac{1}{2}$), with figures 2 inches high, a single figure on a tag. Of course there will be all the figures from 1 to 0; then if you want to tag No. 134 you will use the three separate tags, 1, 3, and 4. This will not be so convenient as the three figures on one tag; but I suppose it can be furnished cheaper. [The objection to the metal tags is the expense. If the demand were large enough, the numbers might be lithographed on the metal, making the cost merely nominal; but as a matter of fact the demand is very limited. But what is the matter with the manilla cardboard tags boiled in paraffine? We use them exclusively here at Medina, and have for the last four or five years. They are cheap enough so that, when they become soiled or faded, a new number can be put in their place.—ED.]

NOTES FROM CANADA

J. L. BYER, Mt. Joy, Ont.

I have just learned of the death of Mr. Checkley, one of the inspectors of apiaries in eastern Ontario. Only a few weeks ago friend Chalmers, another inspector, also passed away. Truly death is taking a heavy toll among Ontario beekeepers the present season, for in addition to these two named, Mr. Pettit, father of our Provincial apiarist, passed away in the early spring.

An article on tobacco-raising in GLEANINGS! Whew! I happened to open March 15th issue, just at the page where the article started. First the article was read, and then I turned over to find the explanation, which was sure to be there somewhere. Well, Mr. Editor, the explanation is satisfactory, even if our finer susceptibilities did receive a bit of a shock at the unexpected; and now who knows but that, in the near future, we may see honey advertised as being slightly mixed with tobacco? Let me say that such an advertisement will not entice this honey-eater, as some of my friends have given it a bad reputation, and I will not take any chances in the matter. Last fall these friends referred to attended a church conference down in Pennsylvania; and while visiting at a home there honey was served. On asking what kind it was, they were informed that it was "tobacco" honey. With considerable misgivings they started to eat the honey, but soon found that it wouldn't go, as they tell me it had the genuine tobacco taste. Of course it may be a matter of getting used to it, as these same friends of mine told me that they could not stay in the tobacco barns on account of the burning that would affect their eyes and nostrils, while to the "natives" no harm resulted.

"Things do move" in the work of bee-journal men, the same as in other occupations. While I had been given a hint relative to the fact that the *American Bee Journal* was changing hands, the May number of the *Review* gave me a genuine surprise when I learned that the latter was being taken over by the National Association. While I regret very much to see friend York retiring from the *Journal*, yet I feel that it could not very well have fallen into better hands; and with a host of others, I wish Mr. Dadant abundant success in his new sphere of labor. I say "new," but after all that is hardly the word to use, as Mr. Dadant has been a well-known writer for apicultural journals, both home and foreign, for a long time—in fact, for so long a time that some of us younger fellows can not remember seeing bee journals without some reference to him.

The change in the *Review's* management is indeed an experiment for this side of the world. As to my private opinion in the matter, so far as the National is concerned, perhaps it would be best to reserve

judgment for the time being; at any rate, being a Canuck I am somewhat of an outsider, and might be accused of patterning after "Butinsky" if I offered any comments. I believe the general impression is that friend Tyrrell is "making good."

No doubt many have heard of the story of the chronic grumbler who lived on a certain farm. On being congratulated because of the very heavy crop in his field he replied, "Yes, it is a good crop all right; but such heavy yields are awfully hard on the land." I was reminded of the story to-day as I was driving home from one of the out-yards, when I recalled that it was with mingled feelings that I found many of the colonies in the apiary so full of bees and brood that something will have to be done before fruit bloom to keep them from swarming, if weather conditions should be favorable for the next two weeks. This is a late spring, and to-day (May 10) the pussy willows are still in bloom in some places in the shade. As I drove to the yard, the first time for weeks, I was hoping that the bees would not be weak, but just strong enough so that they would not have to be supered for fruit bloom. The reason is that I am shipping a load of bees, and am so rushed with work that I do not know how soon I can go to this yard again. Instead of the "just right" condition I had been hoping for, as already stated, some of the colonies were clustered out at the entrance, although the brood-nests were equal to 12 Langstroth frames, and we have had only a few warm days so far this season. It is needless to say the culprits were not Italians, as the latter were not so precocious, and will not suffer for a week or two, although most of them are in fair condition.

Some have reported a heavy consumption of stores the past winter; but such has not been the case with our bees unless they were stronger than usual last fall. For some reason, although we have had an abnormally cold winter and a very late cold spring, the bees that came through the winter well are very strong for the time of year. I am sorry to say, however, that in our section a good deal of the little clover we had left last fall is killed by the late spring frosts. By the way, just a few days ago one of my friends chided me for giving such pessimistic views of the prospects in our section, and remarked, "Why, the most of the fellows over the line think that Canada is about as big as a postage stamp; and when they read your notes in GLEANINGS they will come to the conclusion that there will be no honey in Canada in 1912." For fear this might be true, let me say that, in many parts of our country, the prospects are good; yet, on the other hand, many localities have but very little clover, owing to the terrible drouth of last summer.

Beekeeping Among the Rockies

WESLEY FOSTER, Boulder, Colo.

PARCELS POST.

What advantage is it going to be to the beekeeper to have a parcels post with a limit of eleven pounds, and a charge of twelve cents a pound to send it, when he can send merchandise by express clear across the country for half that amount, and no limit as to weight? It looks as if our servants were listening to the express companies, and also perhaps accepting their franks. We shall not get relief until the postoffice competes with the express companies, which will mean that they will be forced out of business. Why are they allowed to operate in violation of the law, as they are doing? Perhaps we should not ask for parcels post at all but should demand an enforcement of the law.

WHAT MAKES BEEKEEPING WORTH WHILE.

The ideal home is one of many interests. But one point about this ideal home is that all the interests center in and radiate from the home. The children stay at home because they would rather be there. The girls help with the housework, and practice on the piano. Then there is the workbench, and the garden and horse and cow for the boy to help with. Games and children's magazines, and music in the evening, will easily make home most attractive to children. If home is bright and pleasant it will not hurt the children to get out once in a while either.

One of the happiest memories of my boyhood was the fact that my brothers and I had free access to all the tools on the place, and we used them at the workbench. We had a cigar-box telephone from the house to the barn, and we could hear the pigeons cooing in the barn; and when we were in the barn we could hear sister playing the organ in the house. Then we had a stone-derrick in our cellar, like the big one in the stone-quarry near by. We made it ourselves, and cars and track. Practically all our play-things we had to make, which was good for us. Then we had each a piece of garden and a hive of bees. Pa would sell any thing to us that was on the place, and let us pay for it out of the sales. Brother and I bought the chickens, and sold eggs and chickens at the college boarding-houses. Then I went into Belgian hares and raised over a hundred. I didn't make much, but it was lots of fun. But the pigeons! ah, they were the real pleasure, with their cooing and fighting, and mother protesting because they would alight on the roof, and that did not improve the rain water. But we kept the pigeons. We had commys, just common pigeons, you know; then we had fantails and tumblers. We could tell every one of our birds on the wing half a mile off. And what rejoicing when one of ours would coax

a mate from some other farm! and what a sense of loss when one of our fantails got coaxed to some other place!

Nothing is finer than a home with children all alive and interested in the work and pleasures to be found on a small plot of ground, and a roof with love permeating it all. I think father and mother enjoyed their children's enthusiasm, and bravely stood the care and worry the younger ones could not know.

Do not these things make the life of a beekeeper worth while? If you are a beekeeper, and do not have this community of interests in the home and its life, I assure you that you are missing some of the richest things in life.

SELLING HONEY FROM DISEASED COLONIES.

Do you know the law in regard to foul brood in Colorado? Perhaps you are violating it unwittingly.

How to produce honey in a foul-brood district, and at the same time be reasonably sure that no diseased honey is sold, is a problem. But it can be done, and there are a few who are doing it profitably. Inspection and treatment will, perhaps, be necessary three times during the season. Inspecting and treating every diseased colony early in May or June will prevent the storing of much diseased honey later in the season. During July or August, another inspection can be given, and all honey stored by diseased colonies should be treated the same as the honey in diseased brood-combs. All colonies found diseased during this inspection should be treated the same as during the first inspection in June.

A large amount of fine honey may be obtained from these colonies; but it should be extracted or rendered, and labeled as foul honey. It can then be boiled thoroughly and fed (a questionable practice), or it may be made into vinegar. Such honey can be used to good advantage by bakeries if the empty cans are cleansed with live steam and not thrown out on the garbage-pile. The laws of some States prohibit the sale of honey from diseased hives; but it is difficult if not impossible to prove the violation of the law in most cases, so honey is constantly sold in this way. It is useless to have a clause in a law that can not be enforced.

If honey from foul-brood hives is sold to bakeries it would be a good plan to instruct the bakery of the nature of the honey, and to require those in charge to report the treatment and disposition made of the cans. It might be well to have these cans shipped back to the producer of the honey, and require the producer to obtain a permit to sell diseased honey. A record could then be kept of the whole transaction.

Conversations with Doolittle

At Borodino, New York

SIGNS OF SWARMING.

None of the books say much that is of any service to the ordinary apiarist, about the reliable signs of swarming. How do you know that a colony is about to swarm?

I suppose the reason the books have little to say about "the reliable signs of swarming" is because these reliable signs are mostly missing in an outside diagnosis regarding the issuing of the first or prime swarm from any colony. Of course there are indications that point toward the time when the prime swarm may issue; but it frequently happens, after all, that the season for watching for swarms may pass away without the issuing of a single swarm. Again, some of these signs may not appear at all; yet a swarm will issue, and one can hardly believe his eyes in seeing the bees pouring forth from that colony which he supposed would be the last to swarm.

There is no need of watching for swarms before the fruit trees blossom, in any locality where such trees abound, as these are the first which give nectar enough to tempt swarming; and, as a rule, with colonies in normal condition, not one swarm issues during fruit bloom, even in large apiaries, more than one season out of five. To digress:

If a colony supersedes or loses its queen five or six days before fruit bloom opens, then one may expect swarms from that colony about the middle of fruit bloom, if the colony is strong in bees. But such a swarm could not be considered a prime swarm, although it might properly be called a first swarm. A prime swarm is one issuing with the old or mother queen which has lived in the colony over winter. To be a little more definite, any swarm with the accompanying queen being the mother of the bees composing the swarm, can be properly called a prime swarm. All other swarms, or those having virgin or unfertile queens, should be classed as after-swarms, even though they are the first swarms of the season. But no swarm need be expected during fruit bloom, except from very strong colonies, and such colonies are the exception at this time of the year in the greater part of the United States. Swarms during fruit bloom are hardly frequent enough to pay any one to neglect other work to keep watch.

We used to have a good flow of nectar from the black locust, which came long enough before the clover so that considerable swarming was done at the beginning of clover; but the most of these trees, being of value for fence-posts, have been cut down, so that source of supply is cut off. When clover appears, one may expect swarms from all colonies which have become strong enough so that the bees cluster out on sultry days; and by the time the clover bloom has yielded nectar for a week or ten days, swarms are likely to issue from any colonies which may be considered fairly good ones.

The above is about all that can be said from merely outside appearances. Some say that bees scraping the outside of the hive, many drones flying, or any strong colony that has been at work with vigor, and then appears listless, are sure signs that a swarm will issue within a day or two; but from over forty years of experience I fail to find these any thing more than a "happen so."

If one looks inside the hive he can get much closer to indications regarding the issuing of the prime swarm; but even this is not altogether satisfactory. If he finds queen-cells with drawn-out thin side walls, in any strong colony at the beginning of clover bloom, he naturally comes to the conclusion that eggs will soon be deposited in these, when, as a rule, the swarm will issue eight or ten days later. If eggs are in these cells, then he may figure that the swarm will issue from six to nine days later, according to the length of time these eggs have been deposited; for the rule is, three days in the egg and six days in the larval form, at which time the queen-cell is sealed up; and with the sealing of this first cell comes the issuing of the prime swarm, unless unfavorable weather interferes. But for the apiarist with from 100 to 500 colonies, this examination for queen-cells of different ages is a task seldom undertaken.

I said that, as a rule, the prime swarm issues with the sealing of the first queen-cell. But at times the exceptions will almost equal the rule. During a year when the bees seem to get the "swarming fever," little attention is paid to rule, swarms issuing with the laying of the first egg, or the hatching of the first larva, or at any point between the egg and the sealing of the first cell. Then bad weather may keep the swarm back until the young queens, which mature seven days after the sealing of the cell, may be cutting their way out of these cells.

Over forty years of experience have taught me that, four years out of five, nineteen out of every twenty swarms issue according to rule; and the smaller the apiary, the nearer to the rule do they issue; that when they do issue according to this rule, the first young queen emerges from her cell seven days after the prime swarm issues, begins to pipe on the evening of the eighth day, and the first after-swarm issues during the afternoon of the ninth or the forenoon of the tenth day after the issuing of the prime swarm. The second after-swarm issues two days later; and where more are tolerated, an after-swarm will issue every day till the colony becomes so weak that swarming is given up. After-swarming may be prevented easily by cutting off or destroying all queen-cells during the early morning of the next day after a piping queen has been heard the night before.

ISLE-OF-WIGHT DISEASE

Infectious Paralysis is Curable

BY SAMUEL SIMMINS

In your issue for Jan. 15, 1912, our friend Mr. D. Macdonald gives a very gloomy view of the above disease; but his conclusions are in some cases based on error. The disease is curable and can be prevented.

While Mr. Macdonald refers to only a tithe of the large apiaries that have been wiped out, your readers will be interested to know that, almost without exception, the bees thus suffering were mostly blacks or common hybrids; and in many cases no foreign blood had been introduced for many years.

In 1908 terrible havoc was caused among the bees over a large district in California by a plague of infectious paralysis. New South Wales was visited by a similar trouble in 1894 and other parts of Australia in 1906, when over a large area it was almost impossible to find an apiary without some trace of it.

The trouble has been referred to at various times by a number of American contributors to the journals—from Florida, Michigan, Ohio, Mississippi, etc., from 1890 onward. A notice in *GLEANINGS* for July 15, 1896, expressed the editor's fear that bee-paralysis was spreading over the whole of the United States; but such has not been the case, apparently, and never will be, for just here we come right to the true reason why such a dire event can not result in fact. Bee paralysis will never make headway where the majority of owners use only Italians. I am not saying that these bees are absolutely immune; but should they become infected they more readily recover. I believe the same partial immunity will be found in the case of Carniolans and Cyprians.

In my own apiary I keep no native bees, and I am exempt from the disease. I know of apiaries, in the center of the ruins of hundreds of native stocks; but the former, consisting of a high grade of Italians, remain, and do well all the time.

THE CAUSE OF BEE PARALYSIS.

This is patent to any observant beekeeper; and without troubling as to the actual origin, the practical beecowner will see how easily the malady may be overcome. Instead of being a more serious trouble than foul brood, as many panic-stricken beekeepers declare it to be, it is really one of the most simple of any bee disease to deal with. Fortunately neither the queen nor the brood is affected, so that there is a good foundation to work on.

The complaint can not be said to come as a thief in the night. Mr. Macdonald himself, as well as many others, introduced it to their apiaries by buying swarms from infected places. But where not actually con-

tracted by robbing, it is well known that the disease may exist, and has done so, in an apiary for a whole year, or even longer, before the beekeeper is awake to the reality of the visitation; and he finds he has been asleep for months while the thief has been with him all the time in broad daylight.

The only reason why the sick bees wander about on the ground, or climb on to the blades of grass, without being able to fly, is because the spiracles are practically closed, and the air sacs and trachæ are congested. This is the cause of the final trouble—constipation, or inability to evacuate.

We therefore need not concern ourselves much about the origin or the definite disease germ causing the first symptoms. We have simply to remove the obstruction by enabling the bee to fill again its air sacs and trachæ, while at the same time applying a suitable medicinal agent.

MOIST HEAT OR GENTLE STEAMING

has been found to be the basis of recovery, while adding the necessary curative agent. In the *British Bee Journal* for Oct. 5, 1911, I assured my readers that a paralyzed and bloated bee picked up from the ground, as it crawled helplessly about (in the hot sun at a temperature of 100°) would fly after being held in the closed moist hand for a few seconds. This is a most simple fact; for, though the dry heat could not help the sick bee, the warm moisture immediately acts upon the air-vessels, which are at once filled with life-giving oxygen, and the bee is off on the wing before relieving its overloaded bowel—an event afterward accomplished because of the normal pressure then exercised by the intake of air.

I have offered my numerous unfortunate correspondents a method of effectually steaming the whole contents of the hive with most satisfactory results; and after my letter to the *British Bee Journal*, as above, the moist-heat basis of cure was repeatedly proved to be a fact in truth and deed.

Readers found that, after the application of warm moisture, as I had directed, those hitherto helpless bees were enabled to fly again as well they ever did; while in other cases, where my definite treatment of saturating the bees (short of drowning them), with a warm curative solution, has proved eminently satisfactory.

In my own opinion it is sheer folly to destroy any thing unless it be old quilts or possibly soiled combs—the latter seldom occurring with genuine Isle-of-Wight disease or infectious paralysis. Where soiling has been noticed, it can be only a case of severe dysentery, or this trouble overtaking the sick and degenerate bees. Otherwise the paralysis is often evident with no sign either of accumulations in the intestines nor any unusually distended state of the abdomen.

Even in summer the paralyzed bees are

more numerous after they have been confined by dull weather for a few days, many workers dropping to the ground as soon as a general flight is attempted. The very simple plan of spraying these affected stocks with nothing more than warm water daily, while they are thus confined, would alone save the whole of these otherwise condemned bees; but this does not imply that they would be permanently cured without a suitable medicinal agent. The want of water alone is a very serious detriment to the sick bees, not only when the weather does not permit of flying, but from the first state of infection the bee requires that moisture, although it is becoming too lethargic to make any attempt to secure it.

I had a serious experience with bee paralysis in 1878, and had no difficulty in overcoming it without loss of stock; consequently I do not share that feeling of panic and the hopeless outlook exhibited by the majority of English writers to-day.

CHANGE OF QUEENS.

In my early experience referred to I found great benefit result from the removal of the queen, giving a vigorous young one just laying. This plan must always be considered a great factor in the cure of any bee disease, as I have always pointed out from the issue of my earlier works.

The addition of fresh healthy brood and young bees is almost equally important. Black bees, and also any but young queens of any race, must be condemned where there is any fear of this malady. Some contributors to *GLEANINGS*, perhaps ten years or more back, declared that they disposed of the trouble by collecting and destroying the crawling bees daily, and until they did so there appeared to be no abatement of the disease. This would probably be a sufficient remedy in some localities where Italians were used; but it is one that should be rigorously carried out in all cases of paralysis.

I do not consider that the honey is affected. Combs transferred from diseased hives have been known to transmit the disease, but that does not prove that the honey contains germs of the disease; neither is there any reason for supposing robbers carry home the germs in the stolen sweets rather than by contact with the general contents of the hive they may visit.

As a matter of fact, both hives and combs are readily disinfected without removing or unsealing the honey; and I certainly would not advise any unfortunate owner to expect permanent recovery from any treatment unless he also thoroughly cleanses his hives and fumigates the combs with sulphur, or otherwise disinfects them, as they may be removed free from brood.

Heathfield, England.

[Our correspondent seems to imply that the Isle-of-Wight disease, so called, is nothing more nor less than our old friend the enemy, bee paralysis. When we went over the Macdonald article in our Jan. 15th issue, it was our purpose to attach a footnote

calling attention to the fact that the symptoms of the Isle-of-Wight disease were almost the same as those given for bee paralysis; but the form containing it went to press while we were absent, and consequently the footnote did not appear; but since this article has come in from Mr. Simmins, we are more than ever convinced that the Isle-of-Wight disease is our old friend, bee paralysis. We do not know much about the moisture scheme of cure; but we suggest that some of our friends in this country who have the disease try it out and report.

In this connection it may be interesting to know that the Bureau of Entomology, by the direction of Dr. E. F. Phillips, in Charge of Apiculture, has sent one of its men, Mr. Demuth, to Florida, to study bee paralysis. We are glad to know that Uncle Sam is going to study this hitherto unknown disease. While we do not believe, as we formerly did, that bee paralysis is going to prove serious over the whole country, yet if we could know its real cause we would be in a much better position to handle it.—Ed.]

EUROPEAN FOUL BROOD

Is it Necessary to Kill the Queen or to Melt the Diseased Combs? Shaking Bees on Clean Combs, and Placing Diseased Combs Above an Excluder

BY PERCY ORTON

Mr. V. V. Dexter, North Yakima, Washington, March 1, p. 145, asks for articles on producing extracted honey and keeping bees healthy in yards where foul brood exists. If he means European foul brood or black brood I am willing to give my experience. I wish those California (and all other) beekeepers would give this a trial, and not worry so much. I used to worry; but since discovering how easy it is to rid combs of the disease, and to secure large crops of extracted honey without destroying any combs or killing any queens, I have taken real pleasure in the work.

When foul brood first appeared in my yard I was told to melt up all combs, which I did, including some from colonies which were perfectly healthy. Among them was one colony of Carniolans with an extra amount of healthy brood. I questioned the advisability of doing so; but my informant said it would be safer, for it would be only a short time before all of the others would be diseased. I repeated this same wasteful and useless method until I could not raise money to buy any more foundation to fill the frames.

One day I took 50 Hoffman frames of diseased brood and stacked them over a colony with an excluding zinc between, and left them for a month for what healthy brood there was in them to hatch out before melting. Upon examining them at the end of 30 days I found that they were all cleaned out nicely, the cells being polished like

glass. Unbeknown to our good inspector, I concluded to try to use them again for brood-rearing, and I am happy to say these combs and hundreds of others can be seen in my yard this summer, that were very badly diseased in 1906.

Next I wish to say that European foul brood or black brood does not always injure a queen. Hive No. 37 had a Caucasian queen of the 1908 rearing, which was clipped in 1909. This colony showed black brood developing. The combs were removed, and drawn ones were put in their place. An excluder and hive body were placed on top, the bees and queen from the diseased combs, shaken and run into the lower hive body on the empty drawn combs, and the diseased combs put in the top story. The way I manipulate combs to effect a cure, the queen can not deposit eggs in the combs on account of being unable to pass through the zinc, and the bees have ample time to clean them up in 30 days. If the combs are not wanted elsewhere, they may be left for extracting. In 1910 this same colony, No. 37, was the first one to show any signs of the disease. The queen was found; and, being clipped, I knew she was the one in the hive in 1908. The combs were manipulated in the same way again, and this queen produced bees that gathered over 175 pounds of extracted honey, not allowing for any that went with the cappings.

I have used this plan for the last five years without killing any queens, and have taken as high as 261 pounds from a single colony thus treated. What more can be desired? Why the cruel killing of good queens? Do you think I fear black brood? I would not care if a beekeeper located a lot of bees with European foul brood just over the fence from mine if overstocking did not rob me of the nectar that my bees should gather.

I once saw a picture in GLEANINGS of a group of men who, the editor said, were college-bred men inspecting for disease. I wondered what help they would be to some poor beekeeper who had European foul brood in his hives. Those college-bred inspectors would say, "Mr. Jones, we find your colonies have European foul brood. Now, you shake every one of them on to starters to-night." (The next day about half of them would swarm out from the sudden change from combs of honey to starters, according to my experience.) "And at the end of two days shake them on full sheets of foundation. If it reappears, repeat the same operation until a cure is effected."

Now, is that very encouraging to the man who has about 100 colonies to treat? He can figure on spending \$100 for comb foundation, and have no honey to sell, and his old trouble may break out again. If he should have any extracting combs on hand at the time, the chances are these inspectors would recommend melting them for fear there might be disease in them.

If the Alexander method of treatment, which is the killing of the queen and requeening in 28 days, or mine, by the use of

another set of combs, not killing the queen, but keeping her laying, and the bees gathering a crop of honey, had been urged upon the beekeepers of the land by the bee journals, this European foul brood would not have caused the expense it has to the beekeepers and to the government. This treatment does not tend to increase the sale of queens or comb foundation. Both are good when used at the proper time, but not for the sure cure of European foul brood.

Northampton, N. Y., March 20.

[A sharp distinction should be drawn between European and American foul brood. While it is probably true that under some conditions we can save combs that have been affected with the *European* type of the disease, it is not possible to save those which have been affected with the other type; namely, the American.]

The Orton treatment in some respects is similar to the Alexander method that was exploited so much some three or four years ago. Mr. Orton, in his treatment, uses the same basic idea; namely, keeping the queen away from the combs for a period of thirty days. During this time, the bees clean up the combs, polish out the cells and apparently render them fit for use again. We remember looking through Mr. S. D. House's combs at Camillus, New York, which he said had been rotten with European foul brood some years ago, but at the time of our visit were perfectly clean and contained healthy brood.

We were not aware that either American or European foul brood in any way affected the queen bee. Our correspondent seems to take the view that some authorities hold that the queens themselves are "injured." We have so far seen no proof to that effect. —Ed.]

A CAUTION IN REGARD TO THE AFTER-TREATMENT OF FOUL BROOD

Disease Carried by Combs Reserved from a Previous Year, Although no Suspicious Brood had been Found that Season

BY G. C. GREINER

For the last two or three years, being surrounded by foul brood within a few miles of my place, and expecting a call from the dreaded visitor at any time, I have taken extra pains to read every thing I could find on this subject, to prepare myself for a successful combat whenever occasion should force it upon me.

Well, the disease appeared early last spring; and by the time the white-clover flow opened, the whole apiary, with the exception of a few scattering Italians, was fairly rotten with the disease. During the clover flow, every diseased colony was shaken off on starters, Italian queens were introduced, and the contents of all infected hives burned up.

When the spring had nicely opened, I found myself the possessor of a large lot of

empty hives; and, for reasons that I can not explain, all the last colonies had died from queenlessness. There was not a sign of brood of any kind to be found in any of the combs; and as all of them had been built on full sheets of foundation they were what we would call perfect combs in every respect. Later on in the season, as I had not seen the first suspicious sign of foul brood in 1910, I had no fear of using these combs. I knew well enough that nearly all the new combs built on starters by the shaken-off colonies would be more or less irregular, and I intended to use these good (?) combs to exchange with them and fill out the hives later on. All, or nearly all, the *new* colonies I had reduced to five or six frame capacity, according to the strength of the colony at the time of shaking off, and I considered these combs, in addition to the full sheets of foundation, just the thing to fill out the hives.

With the advancing season, which brought us a fairly good honey-flow or flows (we had clover, buckwheat, and fall flows), the progress in the hives was all that could be expected. The starters were rapidly drawn out, and stocked up with brood by the introduced Italian queens, and nowhere could the reappearance of the disease be noticed. As combs grew larger and brood began to hatch, I deemed it advisable to begin sorting out undesirable combs, especially those that were nearly all drone comb, replacing them either with full sheets of foundation or with some of these reserved combs mentioned above. Whenever the conditions of the different colonies would admit I inserted foundation or combs in the middle of the brood nest or began to remove the division-boards I had used for reducing the hive space, and filled out in the same way.

I hardly need to say that I kept close watch on all growing brood; and just when I began to flatter myself of my achieved victory I received a setback that caused me no little anxiety. Many of those inserted combs showed again signs of disease. To be sure, only a few scattering cells were visible; but the disease was there just the same. However, later in the season all affected brood disappeared again of its own accord. What the outcome will be, whether the trouble will reappear this year or not, is a matter of conjecture. Time will tell.

The foregoing experience shows very forcibly that we can not be too careful in battling with the disease. Although I had a little fear of using these old combs, this was removed by the opinion of our foul-brood inspector. When the latter called at my place last spring we examined these combs very closely; and after I had given him the history of them he did not think it would be dangerous in the least to use them again as I proposed.

I can not say positively that those old combs were infected. The disease might have appeared on perfectly sound combs any way; but as no signs of infection were

noticed on combs the bees had built themselves from starters, nor on any they had drawn out from inserted full sheets of foundation, the appearance leans a little in that direction. If I had to repeat the whole program I would rather err on the right side. I would consign all combs, sound as they may seem, to the furnace, or, as in this case, to the wax-press, and use full sheets of foundation instead. The actual loss, outside of the trouble of making the wax, would not be of sufficient consequence to run the risk of making a failure of the treatment, for the wax so obtained would nearly if not quite pay for the foundation used.

We are advised to render all diseased combs into wax, and thus save at least a little from the destruction. From a financial point of view this may seem plausible; but to handle this rotten mess is a most disagreeable job, to say nothing of the danger connected with the work. All our tools and appliances used in making the wax would necessarily be infected with the germ of the disease; and instead of putting a stop to its ravages we would assist, or be liable to, in spreading the disease. The best, safest, and (in the end) the cheapest way of disposing of all the diseased combs and other contaminated traps is to annihilate them in the quickest and shortest way that will accomplish it. This, from experience, would be my advice.

La Salle, N. Y.

[If there are only a few diseased combs it undoubtedly would be cheaper in the end to burn them; but if there are a good many the loss of the wax amounts to considerable. If the old combs are boiled in plenty of water—not simply brought to a boil, but boiled and stirred, and boiled some more, there is no danger. Such work, if not done in a screened building, should be done at night, and all cans or utensils that came in contact with the comb before it was boiled, or with the honey dripping from them, should be thoroughly cleaned and boiled out. All old boxes, sacks, or baskets holding the comb should be burned.—ED.]

HOW PROPOLIS IS COLLECTED

Some Further Notes on Pollen-collecting

BY F. W. L. SLADEN

Thinking it would be impossible for the bee to pass a gummy substance like propolis through the leg to the corbicula, as it does the pollen (March 15, p. 172), I removed a cover from one of my hives and exposed it in the apiary to the warm sunshine to see what would happen. A bee soon alighted, and, after making several futile attempts, succeeded in detaching with its mandibles a little bit of propolis. Seizing the fragment in its fore legs it dashed it on the left corbicula with the left middle leg, patting it on the corbicula with the metatarsi of this leg. Further fragments were detached, and passed on in

the same way, some being transferred by the left middle leg to the left corbicula, and others by the right middle leg to the right corbicula. It is possible—though the motion was too quick for me to see it—that the fragments were caught by the middle leg on the angle between the tibia and metatarsus, and held by the spur on the tibia.

Thus the bee loads its corbicula with pollen in one way, and with propolis in another way, the former substance being combed into a receiver below the corbicula from the metatarsus of the opposite hind leg, and squeezed out on to the corbicula by the straightening of the leg, and the latter being plastered direct on to the corbicula by the middle leg of the same side. It is possible that the latter process is sometimes used in the case of pollen, and I have seen honeybees patting the pollen that is on the corbicula with the metatarsus of the middle leg. This patting is evidently an essential part of the process of loading the pollen on the corbicula; for when I load a dead bumble-bee's corbicula artificially I find that the pollen stands out and needs to be patted down in order to make it lie on the corbicula as it does in nature.

Hoffer, in *Die Hummeln Steiermarks*, Vol. I., p. 37, states that the bumble-bee brushes the pollen out of the body hairs with the two first pairs of feet into the mouth, and there chews and kneads it with honey and saliva into a sticky paste which is conveyed back again with the feet, and pressed with the help of the middle legs, on to the corbicula of the hind legs; and Crawshaw has lately drawn attention to the fact (which may be easily verified by watching bees working on the many flowers that are now out) that the honeybee often gathers pollen direct from the anthers with the mandibles, which are used to knead it. This kneading of the pollen in the mouth explains the source of the honey in the pollen, and makes it unnecessary to assume that the legs are moistened with honey to make the pollen adhere to them. Nevertheless, from observations I have made I believe that the legs are moistened in some flowers.

Ripplecourt, England.

FORMING NUCLEI OVER STRONG COLONIES FOR QUEEN-REARING

BY ISAAC F. TILLINGHAST

By the modern methods of commercial queen-rearing, fully described in the books on the subject, it is comparatively easy to produce a large number of first-class virgin queens from selected mothers; but it is more of a trick to carry them forward past the period of impregnation and into fully developed motherhood. To accomplish this in quantities greater than is required for home use, some form of nuclei is required.

The system of baby mating-boxes in general use by many breeders has never ap-

pealed strongly to me, mainly on account of the expense and trouble required in getting them started. I much prefer confining myself to the use of standard-size frames which may at any time be transferred to and from my full colonies; and then when through queen-rearing for the season, may either be built up to a size suitable for safe wintering or united and reduced in number as circumstances seem to require.

The best way of making these nuclei that I have ever tried is, first, to tier up as when planning for extracting or for increase by the Alexander plan. If the colony contains a queen which one wishes to breed from, and cells are desired, a complete cutoff of wire cloth or paper is put on the queen-excluder, and left from 24 to 48 hours, when it may be removed. The advantage of a sheet of paper is that the bees themselves will attend to the removal by eating or tearing it away so that they may pass readily from one compartment to the other; but in all cases the queen-excluder must remain in order to confine the old queen below; and if cells are once started they will not be abandoned on account of the removal of the complete barrier.

The colony is then left until the tenth day from the time of division or tiering, when the upper portion is divided into as many two or three frame nuclei as desired, giving each a cell ready to hatch, replacing the wire-cloth cutoff, and after three or four days' confinement giving each an independent entrance and exit, which is usually a $\frac{3}{4}$ -inch hole placed on different sides. These bodies should be carefully prepared with tight division-boards, thus forming separate compartments. Each should contain two frames of brood and one frame of honey. At any time after ten days, when all the brood is sealed, any or all of these nuclei may be transferred each to a full-sized hive body and removed to a new stand, where, by feeding and confining them for a few days, nearly all will remain, and there will be no loss of brood by chilling or lack of nursing, which is sure to take place where removal of unsealed brood is made direct from the parent hive.

Our preference, however, is to leave them on the parent hive, or remove a portion of them to the tops of other strong colonies where they may be benefited by the warmth arising from the bees below. We have but little difficulty in securing fertilization of queens in this way, but find that the wire cloth as well as queen-excluder is necessary in order to make a complete separation.

Factoryville, Pa.

Proof of the Value of a Bait Section

I put one full-comb section with perhaps a dozen cells of honey in the center of the super late in the season. When I took that super off, that bait section was filled full and capped white, a fancy filled section, and scarcely another section in that super had been touched.

Lincolnton, Me.

FRED BREWSTER.

T super containing two extracting-frames with wide end-bars, so that they take the same amount of room as a section-holder.

COMB AND EXTRACTED HONEY PRODUCED IN THE SAME SUPER

Is the Production of Comb Honey without Separators Advisable?

BY E. D. TOWNSEND

Mr. E. D. Townsend:—There is one thing in regard to the production of comb and extracted honey in the same super that is not quite clear to me. You have referred to the regular dovetailed super with $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ two-beeway sections and plain separators. Now, then, my supers are all of the above-described style, ten-frame size, with slotted separators. Can I use these in with the shallow frames, or must I have the plain separators?

Again, would it be safe for me to leave out the separators and follower and springs, and space the section-holders and shallow frames equally?

The reason I mention this is that some of my customers complain that the 1 $\frac{1}{2}$ section is too small; i. e., too much box for the honey it contains. What would please me (if I could use it in the regular super) would be the two-inch section; then I could make them hold 1 lb. of honey, or very near it. As before stated, my supers are all regular, of ten-frame size, and, with the separators and follower, hold 28 1 $\frac{1}{2}$ sections. Mr. Mondeng, of Minneapolis, tells me he produces nice marketable sections without separators, and has no difficulty in getting the bees to go into them; but I want the shallow frames.

Elroy, Wis.

CHAS. SHELDON.

I can see no reason why a shallow extracting-frame will not interchange with any section-holder in your ten-frame super. The end-bars of the extracting-frame should be made the same size as the end-bar of the section-holder, and the top and bottom bar but $\frac{3}{8}$ inch wide, so that the comb may be uncapped more easily. The slotted separator ought to work well with this combination.

Good comb honey *can* be produced with-

out separators, but it is not advisable in your case. It is a fine art to produce nice comb honey without separators, and it would take you years to acquire the "knack" of producing honey that would come anywhere near up to the standard of that produced between separators. I have seen a few beekeepers who have acquired this knack, but these were some of the older ones who began before there was much done along the line of separators.

In arranging the super where no separators are used, sections that are partly full of comb from the previous season's use should be grouped together, according to the amount of work that has been done in them. The sections that are nearly full of comb should be put by themselves, and a super filled with them. Those sections that are only partly full or comb should be arranged in supers containing combs of about the same thickness. New sections containing only foundation starters or full sheets, as the case may be, should also be put in supers by themselves. If one were to alternate sections of drawn comb with those having but foundation, the sections containing drawn combs would be drawn out into great thick combs, while those having nothing but foundation would be very thin, some being hardly touched, and therefore not marketable. By keeping each kind of section by itself, as explained above, very good work can be expected without separators.

One of the more important reasons for using separators at the present time is that the finished sections must all be about the same size and finish, as they sell by the

piece, in most cases. Some 15 or 20 years ago grocers weighed out nearly every thing they sold. Sugar, coffee, rice, and spices of all kinds were bought in the bulk and weighed up in any amount that was wanted. The grocer now hands out a fourth or a half pound, all done up in a nice package. With this method of handling goods there is no shrinkage, and the grocers like it, and will handle nothing but package goods, in many cases, on this account. This is the way that comb honey will be handled in the future; and to make this possible, separators must be used in the production of the honey.

As only two springs can be used to advantage with this combined arrangement of the super, the separators between the extracting-comb and the first row of sections ought to be made as thick as possible so as to hold the sections in place near the center.

With two extracting-frames to the super, one at each outside, any one can get the bees to enter the supers readily, if he will follow the very simple rule of putting the supers on at the first opening of the clover, not waiting until it begins to yield honey, as that would be too late.

I admire your desire to please your customers; but I am very sure you have undertaken a hopeless task. No one can please every one, and the better way is to keep near the beaten trail and produce your comb honey in the orthodox section. Your customer who complains of your selling him too much wood with his 14 ounces of honey would likely complain were you to produce sections of honey weighing 16 ounces and charge him a nickel more for it. The thing that would really please this customer would be for you to produce full pounds of honey, then sell it to him, charging him for only the 14 ounces as usual.

I would advise that you continue to use the $4\frac{1}{4} \times 4\frac{1}{4} \times 1\frac{1}{2}$ -inch two-beeway section, and separators. Use two extracting-combs in each super, one at each outside. When your honey is ready, crate it in the double-tier or Colorado shipping-case. When ready for the market, quote your price by the case, not by the pound.

Remus, Mich.

WHY IT PAYS TO PAINT HIVES

BY FRANK F. FRANCE

In traveling over the country I have run across whole apiaries of unpainted hives, often close to apiaries owned by adjoining beekeepers in which every hive was painted, and I have not failed to notice the great contrast, both in durability and appearance, between the two. Here in the North, if the hives are not painted, at least occasionally, the moisture that soaks into the wood will cause trouble when freezing and thawing takes place. The illustration shows a hive that has never been painted. The nails are pulled out about an eighth of an inch, and the lumber has sprung apart at the corners.

This would not have happened if the wood had been thoroughly painted in the first place, so that the moisture could not be absorbed. A hive left unpainted in this way for four or five years will require more paint to get it in shape than it is worth; and on this account a little paint well applied at the beginning is worth a whole lot in the end. Neglecting a matter of this kind is to spare the cent and lose the dollar; in other words, it means a new hive just a little quicker. This is a serious matter, for the quality of lumber is slowly deteriorating and the quantity diminishing, so that the price is steadily going higher.

WHAT PAINT TO USE.

By all means use pure paint. Pure linseed oil and pure pigments properly united are always the cheapest in the end. Some department stores sell paint by the mail-order plan; but I have found it is best to deal with the very best standard companies who make paint a business alone, for then one is much more likely to get pure material.

FRANK F. FRANCE, SON OF N. E. FRANCE, PLATTEVILLE, WISCONSIN.

Mr. France spent a year in California to get some experience with the producers of the far West, and now he has returned to his native State to take up beekeeping in earnest. May he have as much success as his father and grandfather!

The most durable pigments are oxide of zinc, white lead, lampblack, yellow ocher, and venetian red. There are many others that are good, but I have found these the most suitable for hives in this locality. I have had opportunity of testing many colors in sign-painting, and in old signs I have found that letters painted with lampblack or white lead show the longest.

The paint most recommended for durability is one coat of pure linseed oil thickened with pure yellow ocher well brushed in, and one coat of oxide of zinc or white lead ground in linseed oil to a good body and well brushed in. What I mean by brushing in is rubbing the paint well into the wood and applying the second coat only when the preceding one is thoroughly dry. Two coats of paint thus applied will last two or three years. Many complain of white lead "chalking." This difficulty would be overcome if more linseed oil were used. Lead beautifies and fills the surface, and the oil holds it there.

Many have asked whether it is practicable to paint the hives while the bees are in them. There is no objection to this; but it is well to add a little drier, such as japan and turpentine, so that, if the paint is put on in the afternoon, it will be dry by the next morning.

Any one who has done any buying of late years can understand why the price of linseed oil, pigments, etc., has advanced. The question of the supply and the purity of the product make these high prices. In many of the States I believe there is a law specifying the purity of linseed oil and turpentine, so that those who sell them dare not label them pure unless they are. I am informed that in one State some of the merchants are selling their oil and turpentine as adulterated, though purchased and sold in good faith as being of the highest quality, simply to protect themselves in case of a possibility of adulteration.

But even at the present prices, good paint is to-day the cheapest commodity we have to buy. Paint is a form of insurance that prevents the slow type of burning known as decay. Painters claim that only 25 per cent of the perishable property of this country is protected by this efficient form of insurance. Shall we not insure our hives?

Platteville, Wis.

FRAMES WITH BOTTOM-BARS HALF AN INCH THICK

Are Not the Standard Bottom-bars too Thin?

BY FRITZ BOHNE

Some six or seven years ago I made all my brood and extracting frames myself (by hand), and made all the bottom-bars in both brood and extracting frames half an inch thick, and the bottom-bar with an offset or rabbeted end, so that I could nail it both ways by driving a nail through the bottom-bar into the end-bar and one through end-bar into the end of the bottom-bar. This gave the frames more strength. It is almost impossible to break or pull the bottom-bar from a frame made in such a manner.

The main reason I made the bottom-bar half an inch thick was to start the bees to building the comb lower down in the frame—especially in those extracting-frames which were almost entirely filled with comb, and the comb fastened in most instances to both the bottom-bar and the top-bar.

Then with frames having half-inch bottom-bars I did not run the risk of tearing the comb loose from the bottom-bar nor of splitting it in the middle, as would sometimes happen when taking out a frame with a quarter-inch bottom-bar having the comb fastened to bottom-bar.

The half-inch bar does not bend as the quarter-inch bar does when the bees fasten the extracting-frames to the brood frame

Undecided whether to use smoke at the entrance.

with propolis. In the part of Texas in which I live the bees gather a large amount of propolis.

I have all my bees in one apiary, but I can examine them now and find that the hives containing frames of my own make, with half-inch bottom-bars, are almost all filled out with comb which is fastened securely to the bottom-bar, while the hives containing factory-made frames with quarter-inch bottom-bars have the comb coming within half or quarter of an inch of the bottom-bar, and in some instances fastened to it. I do not mention this in a boasting way, but simply in connection with my experience with bees and frame hives.

Has any one made similar observation? If so, I wish to hear about it. I stopped making my own frames, although I know how to handle tools, because I think I can buy frames much more cheaply than I can make them by hand. If frames with half-inch bottom-bars were manufactured I would have no other.

Washington, Texas.

BEEKEEPING IN CINCINNATI, A MILE FROM THE HEART OF THE CITY

BY ALBIN PLATZ

Believing that it may be of interest to the readers of GLEANINGS to learn of the feasibility of keeping bees profitably and without the slightest danger or annoyance to neighbors or passersby in large cities, I venture to write a few lines on the subject, and enclose a couple of photos of my little apiary. My work confining me indoors eight hours and more every day (I am a letter distributor in the Cincinnati postoffice), I looked about for some means of recreation in the open air and sunlight. In beekeeping I found every thing and more that I could have wished for. It is, without doubt, one

of the most fascinating and healthful of recreations. I keep my colonies (seven Italians and one Banat) in the rear of my yard, which measures but 34×126 feet. My home is situated on Mt. Auburn, a thickly populated suburb of Cincinnati, and within one mile of the heart of the city itself.

I have often been asked whether bees are not a nuisance to my neighbors and others. Decidedly they are not, and I have yet to hear of any one being stung by my bees, or annoyed in any way. My little boy, of three years, often plays among the

hives, and even climbs on top of them, and still the bees do not molest him. I have never heard a complaint—in reality, most people are interested in the little creatures, and it often keeps me busy answering questions regarding them.

As regards the amount of honey secured, despite the limited pasturage, my bees do pretty well. Last year was a complete failure, and, moreover, American foul brood was very prevalent in this locality; but in 1910 I started the season with four colonies; increased to 6; secured 300 lbs. of fine extracted honey, and about 25 lbs. more in sealed combs, which I held over the winter. My honey sells readily for 20 cts. per lb., and the demand exceeds by far the supply; so it is very evident that bees are profitable as well as a pleasure.

I am sure the gentle art of apiculture is steadily growing in popularity in this city; for in the last few years quite a few recruits

Apiary of Albin Platz, in the back of a city lot, Cincinnati, Ohio.

Mr. and Mrs. J. B. Mason, of Mechanic Falls, Me.

have been added to the ranks, and I know of several more who are going to start this spring. With the aid of the several good text-books on this subject, and *GLEANINGS*, the heretofore mystery of beekeeping becomes so simple and clear that the most timid and uninformed beginner can soon become adept in the business, and find new pleasures in it year after year.

Cincinnati, Ohio.

BEEKEEPING FOR WOMEN

The Advantage of Being Skilled in the Use of Tools

BY INEZ A. BEALS

Perhaps many who patronize Mr. J. B. Mason, of Mechanic Falls, Me., may not know that Mrs. Mason is so closely associated with her husband's business. I hardly see how he could do without her assistance, since she knows every detail of the work. I am an infant in the bee business myself; but last spring I was in need of some hives and supplies, so I went over to Mechanic Falls. I had heard of the supply house, and wanted to see the different things kept for the bee business. I found Mr. and Mrs. Mason like friends I had known for years. She invited me into her cozy home. Women who are interested in bees are not as plentiful in the East as in the Western States, so I presume she thought I would not care to visit the supply rooms; but I told her at once that this was just what I had come for. So we went out into an open room, the first of which was Mr. Mason's office; thence into a large high room piled high on either side with hives and furnishings (in the flat) of every description. I wondered how a beginner would know which one to choose.

I was much interested as Mrs. Mason sat

down to nail up a double-walled hive. I think it is fine for a woman to be a carpenter; and surely if she is in the bee business she can apply her skill to very profitable advantage. I bought two L. hives complete, and did all the work of nailing them, wiring frames, etc., and I thought it fun. If I had had a good many it would have been just that much more enjoyable.

Mrs. Mason does a great deal of work of this kind, and Mr. Mason knows well her worth. She showed us a stack of hives she had just painted.

We passed on into another room where we saw beeswax, fine and

yellow; also all kinds of tools used by beekeepers. Another room was for the jars.

Two years ago I purchased a fine swarm, as an investment. It paid me well that year. The first thing I did was to hunt up and clip the queen. The hive was boiling over with bees, as it was quite late; but she was superseded, so they came out later only to be put back, for the honey flow was at its height, and I wanted honey instead of bees at that time. A swarm issued later, so I had two colonies to winter. Last spring I purchased another.

I am always very glad when I can read something written by a woman beekeeper, for so few women are in the business. Let us hear from them.

Lewiston, Me.

TRANSFERRING BY MEANS OF THE SIMMONS SWARM-CONTROLLER

BY DR. L. A. SIMMONS

The task of transferring bees from a box hive, nail-keg, or any old substitute generally employed by those who keep a few bees in the country, is one not to be desired when done by old methods in general use. It often becomes necessary for the beekeeper to purchase bees in hives of every description, of neighbors, in order to get them out of the way. Transferring by the use of the swarm-controller converts this unpleasant task into play. The swarm-controller is adjusted to an empty hive body, as seen in Fig. 3, page 139, March 1, on left side. This hive is provided with frames with full sheets of foundation. The hive on the right is supposed to be the box hive containing the bees to be transferred. This hive is to be adjusted to the swarm-controller, so that the bees are compelled to work out through

FIG. 6.—Another view of the switching-device by itself.

it, as seen in the cut. The entrance to the hive on the left, containing the foundation, is left open. The rear openings of the controller between the two hives are closed, and the feeder end closed with a shutter. The bees now have access to both hives across the front vestibule of the controller.

Thus arranged they may be left to work and investigate the new combination, and become established in using the new entrance. Transferring should be done when the bees are flying well, but may be done at any time if circumstances demand. If there is a honey-flow, and the bees are well afield, about noon, push in the slide on the right side, seen on top of the swarm-controller, provided with a Porter bee-escape, closing the entrance to the box hive containing the bees. The bees can now leave this hive, but can not return. Returning to the common entrance in the controller they enter the new hive on the left. There will be some commotion for a time on account of the absence of the queen. Two combs of honey and brood can be given in the beginning from some colony that can spare them, and this will very greatly aid in satisfying their discontent. If, however, they are black bees, as they generally are, a laying Italian queen is given in the evening of the first day. When the bee-escape is adjusted, closing the entrance to the old hive, the bees having become established in using the controller entrance, the box hive may now have an entrance or exit made on the side opposite the controller entrance; and all bees leaving this exit will return to the controller entrance

and enter the new hive. A sufficient number of bees should be left in the box hive, however, to nurse the brood. In fourteen days the escape is removed, and in its place a slide of perforated zinc is fixed; then smoke the remaining bees from the top of the box hive, and they will go over to the annex. All the entrances between the two hives, front and rear, should now be open except the perforated zinc, so that the bees may readily retreat from the smoke. The call of their

comrades will draw them over, and the trouble of clearing the old hive of the remnant of young bees is thus greatly facilitated. Do not forget to place a slide of perforated zinc over both openings of the box hive to prevent the old queen from entering the new hive with the young bees. The old queen can now be killed by fumigating. As the box hive is not joined to the controller (simply set against it), it may be set aside some distance while fumigating. It is now returned to its original position against the controller, all slides removed, giving the bees free access to the hive, front and rear. Mutilate the combs by pushing a stick through them, breaking the honey-cells. This will induce the bees in the new hive to transfer the honey in a short time.

The box hive now contains nothing but the empty combs, which should be removed, torn down, and the wax rendered before the worms get into it. After the old queen in the box hive ceases laying, and has been deprived of her bees for a time, she shrinks, becoming smaller in the abdomen; and there is then danger, by the above process, that she may slip through the perforated zinc along with the bees when smoked out, and thus endanger the safety of the valuable queen in the new hive. To obviate this risk, the old queen in the box

FIG. 7.—Storing empty extracting-combs in extra bodies over the "annex."

Sweet clover harvested for seed by a self-binder.

hive may be drummed out in the beginning, with as many bees as convenient, and then killed. The hives are adjusted as above described, and as seen in the illustration on page 309, last issue, and the bees drummed out and dumped at the entrance. All subsequent steps are the same as above described and illustrated.

STORING EMPTY COMBS.

Mention was made of storing frames of honey in the annex, taken from the brood-chamber during a good honey-flow. I would here emphasize the importance of this measure as a means of relieving the congestion of the hive at a time when it aids in controlling the swarming impulse. These combs are not taken from the bees, but they at once divide their forces to care for them in their new location. This division of work depletes the hive of a class of workers that naturally retire to a place of least resistance as they grow old and less fitted for the arduous duties of field work, thus adding another element in swarm control. Fig. 7 illustrates my method of storing empty extracting combs over the annexes after the season is over. The few combs with a little honey in, at the last extracting should be left, and also some partly filled sections, as food for the guards while taking care of these empty combs. These should be scattered through the stacks of supers. So long as the weather is warm enough for the bees to leave the cluster they will be found scattered through the piles of combs, and the combs will be kept free from worms and mold, and perfectly sweet.

In closing these three articles I wish to add that, if this discussion had been written for the veteran beekeeper alone, very

much might have been omitted. In fact, it is only necessary for the veteran to see the cuts and illustrations, and get the principle of the method, to see at once the large field of the device. But these articles were intended to explain fully in plain language merely the chief uses of the controller for the beginner and veteran, and therefore it was necessary to give a detailed description of the various manipulations mentioned.

Auburndale, Fla.

THE HARVESTING OF SWEET CLOVER FOR SEED

The Best Time for Cutting; How to Save All the Seed

BY FRANK COVERDALE

The accompanying illustration shows a field of white sweet clover shocked and dry. We stacked this later, and did not hull it until it had gone through "the sweat;" then it hulled out very nice and clean. If hulled when tough and damp much seed would be left in the straw, and a good deal would also be left unhulled.

The harvesting of sweet-clover seed is very easy, as the self-binder ties it up perfectly and without strain. A big field can be tied and shocked in one day; and when in shock it is safe from all elements that might scatter the seed. If the field is harvested when still somewhat green the straw makes considerable roughage for the cattle and horses; but the seed crop will be lighter and of poorer quality. For this reason we now believe that it is best to let the field stand until well ripened—in fact, just as ripe as

possible without having it shell out. If a field stands well filled with ripe seed, a thunderstorm with a high wind ahead of it may blow much seed to the ground; so it is easy to see that the operator should be on the lookout and get the binder in before such a thing happens. The time to bind it is when the field looks well loaded with black seed with but little green seed showing.

If a field has been cut twice for hay, and then is to be cut for seed, a mower with a buncher will be the best to use. If it can be gathered next morning, while dew is on it, into small cocks that can be handled at one forkful, it will be in shape to haul in to the stack or huller at any time. When dry a canvas should be spread over the rack to catch the scattering seed, and this canvas can be emptied into the stack or huller once in a while. Much fine seed will thus be saved, and the canvas will pay for itself very soon. No one should attempt to haul the seed without a canvas over the rack.

The straw turns water splendidly; and if at all well stacked it will be found nice and dry for winter use for bedding or for live stock to pick over. We formerly cut our seed so green that the straw made fair hay, but have since found out that it pays far better to let the seed ripen more, for the yield will be easily doubled by so doing.

One acre of the field shown in the picture was measured off and hulled alone, and produced 11½ bushels. This, by many bushels, broke all records that I have ever known of as a yield of clover seed, and it was in a season when no one else had any clover on his farm, either for hay or seed. This fact makes the sweet-clover business look good to me.

I have used a Birdsell huller, and it does first-class work with this clover. I have also used a common thrashing-machine, and prefer it to any other outfit, as it gets it out very rapidly, and does the work well. An extra set of concave teeth is put in for this purpose, and these are often used for hulling clover. Our machine men arranged the choppers so as to carry off nearly all the finer choppings behind the machine. This made the work go much faster. It is not difficult to run out 150 to 200 bushels of this seed in one day, and this can easily be hulled for 50 cts. per bushel, and even less if sufficient is grown to keep a machine in the field for a one or two weeks' run.

The thrashing-machine has no recleaner attachment, so the seed has to be recleaned from the machine. We count on having our machinist attach a recleaner, then all will be in first-class shape when done.

We cut our stubble ten inches from the ground, and the stalks sprout and bloom all the fall, and ripen more seed, which falls to the ground to reseed if one wishes to let the field grow up to sweet clover the coming year. We have such fields, and will just let them reseed themselves for hog pastures next summer. The bees are very busy on these fall stubbles until frost. In a few days

the stubble shown in the picture was nearly white with bloom, and indeed it was a pleasant sight to see one great row of bees flying to and from this field all the fall.

Delmar, Iowa.

COURSES IN APICULTURE AT OUR COLLEGES AND UNIVERSITIES

BY E. R. ROOT

More and more our colleges and universities are beginning to recognize bee culture, either by establishing regular courses for the study of bees or by establishing a small apiary where students of entomology and botany may, on the side, study not only the domestic economy of the hive, but learn something about the intimate relations that exist between bees and fruit. The Ohio State University at Columbus, for example, has been having, for a number of years back, lectures on bee culture for the benefit of the students in the short winter agricultural courses. The University has also had practical live-bee demonstrations and field work during the summer.

DR. G. C. CREELMAN.

A college President who is enthusiastic over the Apicultural Department at his institution.

The Massachusetts Agricultural School, as announced in our last issue, on page 21, has regular courses in apiculture under the direction and management of Dr. Burton N. Gates, formerly of the Bureau of Entomology, Washington, D. C. Splendid work has already been done, not only in teaching methods of management but in equipping students so that they become efficient foul-

brood inspectors. What Massachusetts is doing is also being accomplished by the Ontario Agricultural College at Guelph, Can. The apicultural courses are under the direction of Mr. Morley Pettit, lecturer and provincial apiarist. We had the very great pleasure of visiting both schools in apiculture, the one in Massachusetts and the other in Canada. The faculty of both institutions, including their presidents, are much pleased with the work done; and it now looks as if apiculture would become a permanent part of the college work.

But this time we wish to speak particularly of the work done at the Ontario Agricultural College. We asked Mr. Morley Pettit, lecturer and provincial apiarist, to tell something about his apicultural school—not only of the work accomplished, but of the plans for the future. In a letter just received he writes:

We have not an apicultural school as such. Our work is in the direct line of the other work at this college. Roughly speaking, there are three classes or courses at this college—the two-year course, which leads to an associate diploma, the four-year course, which leads to a B. S. A. degree, and a number of short courses on special subjects, lasting a few weeks or months each. Students entering for the two-year and four-year courses all take the same subjects for the first three years; then in the fourth year they choose one of three or four options which are provided by the curriculum.

The work in apiculture consists of twenty-five practical lectures and demonstrations to the first-year students; also a short course was held in May, 1911, and the second shortest course in apiculture ever held here was the one which you attended. A few of the students have shown a preference for this subject, and have asked that an apiculture option be provided in the fourth year; but this provision has not been made as yet. It is probable, however, that the subject will be made a major in one of the other options next year.

The students who are specially interested in apiculture have organized a club which has been quite largely attended. It has been addressed by such practical and scientific men as Messrs. Sibbald, Byer, Miller, of London, Dr. Hewitt, of Ottawa, and others.

My work consists in directing this department, also the inspection work of the province and the co-operative experiments in connection with the Experimental Union. The membership of the Experimental Union is made up of students and ex-students of the C. A. C., and the list of experimenters extends over any who are interested in conducting the experiments sent out, such as testing seeds, grains, vegetables, and the like. In apiculture we send out instructions for testing special methods. The last two years we tested methods for the prevention of natural swarming. This will be continued next year. Remarkably good results have been secured.

In addition to this work I have done a lot of organizing in counties and attending local conventions to encourage beekeeping in the different parts of the province. In fact, my traveling is upward of 10,000 miles a year in Ontario alone.

I consider one of the most important lines to be the special course which we give to students preparing for inspection work. Those who do well in the subject in their first year, and wish to specialize, are placed with practical beekeepers for the summer as assistants, where they secure plenty of experience; then during the next term they are given some special preparation on diseases of bees, and their second and third year vacations are spent inspecting apiaries.

Guelph, Can., March 5.

MORLEY PETTIT.

Any reference to the apicultural school at the Ontario Agricultural College would be incomplete without a mention of its president, Dr. G. C. Creelman, one of the ablest and strongest men we have ever met in any

institution, and we have seen a large number of them in the United States. Dr. Creelman is particularly enthusiastic over the work done in the apicultural school. Indeed, he takes pride in it, as he does in every department of the institution; and during his administration the college has made a most rapid growth. In the year just closed there were in actual attendance in all its courses 1557 students, representing 22 different countries, including several States of the American Union. The staff is composed of more than forty professors, lecturers, and administrators. One of Dr. Creelman's assistants said of him that "he directs the work with a happy manner and ready smile, and with absolute impartiality. It is a pleasure to see him at work, for one feels that he has a grasp of the whole situation, and knows just what is going on everywhere, all the time." This is true, every word of it.

Dr. Creelman is right in the prime of life. The students, individually and collectively, love him, and well they may, for his personality is magnetic and inspiring. What struck us particularly was that there are very few presidents of our agricultural colleges who know more of bee culture and its important relations to general agriculture than Dr. Creelman. In fact, we doubt if there is a college president on the continent who can give a better address on bees. The one we heard was sparkling, entertaining, and instructive—so much so that the students who heard him must either have resolved to keep bees for the honey they produce or to pollinate the fruit trees and clovers; for, be it said, Dr. Creelman is an enthusiastic believer in the value of bees in helping to produce more and better crops on the farm and in the orchard.

Later.—After the foregoing was written we received the following regarding the Massachusetts apicultural school:

The Massachusetts Agricultural College has instituted, in its regular curriculum, instruction in beekeeping. We note with particular interest, marking the beginning of an epoch when beekeeping shall be more generally taught in the United States, that they have erected what we presume to be the first building in the country to be devoted exclusively to apicultural instruction. The beekeeping work is under the direction of Dr. Burton N. Gates, of the Department of Entomology. On the 7th and 8th of February Dr. Gates held a convention of inspectors of apiaries of the eastern United States and Canada. We hope to present in the near future more details of this new movement for advancing apiculture which is centered in Amherst, as well as an account of the inspectors' meeting.

With respect to the admission of students to the college for regular enrollment, beginning with next fall the tuition is free to residents of Massachusetts; yet students coming from without the State will be obliged to pay.

A spring course in apiculture, lasting two weeks, and beginning May 24, will be given. A detailed announcement and program may be obtained from the Director of the extension service, Massachusetts Agricultural College. This is essentially a "cram course" for the laymen; and, while its membership is necessarily limited, any beekeeper from any State is eligible.

And here is still another from Wisconsin:

Following a resolution adopted at the Feb., 1912, convention of the Wisconsin Beekeepers' Associa-

tion, requesting the Wisconsin College of Agriculture to introduce work with bees with an offer of a donation of bees and supplies if such resolution were accepted, the Wisconsin University Board of Regents, about the last week in April, 1912, decided to introduce an elective course in beekeeping. This course will be given by Prof. J. G. Sanders, probably the last half of next year—that is, from about Feb. 15, 1913, to about June 15, 1913. An apiary of about ten or twelve colonies will be owned by the college, and be used by students and for experimental use.

From my acquaintance and work with Prof. Sanders I can state that he is interested in beekeeping, and is especially well fitted for giving work in it.

I drop you this little notice as a bit of news, which, perhaps, you may associate with data concerning college recognition of beekeeping.

Madison, Wis., May 4.

L. V. FRANCE.

THE YELLOW FLOWERS OF NORTH AMERICA

BY JOHN H. LOVELL

Owing to the great abundance of buttercups, goldenrods, and sunflowers, yellow is more predominant in the floral landscape of North America than any other color. Yellow may well be our national color, and the goldenrod our national flower. It is the most bright and cheerful of colors, since it reflects the largest quantity of light, and it is doubtless for this reason that yellow flowers enjoy so great a popularity.

Yellow flowers owe their hue to a solid pigment called carotin, familiar to every one in the root of the carrot. It usually occurs in petals in small round granules called plastids. It is insoluble in water, but readily soluble in ether. It invariably accompanies chlorophyll in leaves, and is widely distributed in seaweeds, fungi, lichens, mosses, and ferns, in autumn leaves, and in fruits and seeds. The yellow plastids of flowers are not always round, but are sometimes angular, as in the garden nasturtium. In the tomato, asparagus, thornbush, and in some species of rose, the plastids of the fruit are spindle-shaped, or irregularly shaped, and are fire-red, orange-red, or yellowish red. In yellow leaves the plastids are round; but in autumnal leaves they occur in irregular masses.

The scarlet poppy, tulip, and fire-red canna owe their colors to a mixture of yellow plastids and red cell sap. On the other hand, dingy or dull colors result from a combination of violet sap with yellow granules. In a few flowers and fruits, as the yellow snapdragon, dahlia, and the peel of the lemon, the color is due, not to carotin, but to another yellow pigment (called leaf yellow) dissolved in the cell sap.

Yellow is an old and primitive color, which in its natural state does not vary readily. This may be shown by the following experiment. If the carotin contained in a few slices of the root of the carrot be dissolved out in ether, the yellow solution will not lose its color under ten days, while the green hue of a solution of chlorophyll will disappear in twenty-four hours. But under cultivation sudden variations from yellow to white have been observed. A double yellow hollyhock turned one year into a

single white kind, and a chrysanthemum has been seen to bear both yellow and white flowers. The bright-yellow flowers of the golden currant and the bush honeysuckle in fading change to rose or red; and a species of forget-me-not is at first pale yellow, and changes to sky-blue.

There are 790 yellow flowers in northeastern America which vary greatly in size and form. Usually they are wheel-shaped as in the buttercups and five-fingers; but not infrequently they are very irregular in form, as in the pea and figwort families, where the corolla bears a more or less fancied resemblance to butterflies and the heads of reptiles. As a whole, however, they are much less specialized than red or blue flowers. Irregular yellow flowers probably owe their hue largely to the great persistency of the yellow pigment, carotin.

Both yellow and white flowers are common in primitive families. For instance, in the buttercup family there are 38 yellow and 26 white flowers; in the mustard family, 46 yellow and 54 white; and in the rose family, 39 yellow and 35 white. Since carotin is very widely distributed in the foliage of plants, and petals are only modified leaves, it is not difficult to imagine how the first yellow flowers were developed.

While trees and shrubs with white flowers abound everywhere, as has already been pointed out, trees and shrubs with yellow flowers are comparatively rare. A number of common trees have small yellowish or greenish-yellow flowers, as the rock-maple, striped maple, chestnut, and basswood; while among shrubs there are the barberry, fly honeysuckle, jessamine, and bush honeysuckle; while under cultivation the *For-sythia*, golden currant, and yellow rose are familiar examples. The willows owe their yellow hue to their stamens (they have no perianth), and are, like the basswood and rock-maple, most valuable honey-plants.

Most plants with yellow flowers are herbaceous. When the blossoms are of small size they are usually like small white flowers, grouped with level-topped clusters, as in the mustard, saxifrage, carrot, and thistle families. The most important sources of nectar in this group are the mustard, wild pansy, and goldenrods.

In the pink family, though there are 56 white flowers, there are no indigenous yellow species; and in the aquatic water plants the entire 19 species are white; but, on the other hand, in the St. John's-worts there are 22 yellow and 2 red flowers, while white fails entirely. Yellow is very common among the primroses and night-shades, but rare among the heaths and gentians. Yellow blossoms vary greatly in size, from the large campanulate cups of the squash to the small flowers of the creeping buttercup.

In the aster or thistle family (*Compositæ*) there are 262 yellow flowers and 134 white. Though this is the highest of plant families, the central florets of each head are very small, and the floral leaves have been very

little modified; consequently they retain their primitive hues. In the common field daisy the disc florets number about 500; but in the goldenrod each head consists of from 6 to 15 florets, and conspicuousness is gained by massing immense numbers of them into dense panicles. The goldenrods form a genus of beautiful and stately plants which bloom from midsummer to late fall. Several kinds secrete nectar freely, and are great favorites with the honey-bee. On the Canadian goldenrod 146 different kinds of insects have been observed in search of pollen or nectar. The bright-yellow color of the flowers renders them conspicuous, both by day and evening; and as the temperature of the inflorescence at night is several degrees above the surrounding air, they sometimes serve as a refuge for insects.

And in the evening, everywhere,
Along the roadside, up and down,
I see the golden torches flare,
Like lighted street-lamps in the town.

I think the butterfly and bee,
From distant meadows coming back,
Are quite contented when they see
These lamps along the homeward track.

Among the plants with yellow flowers which are of most value to the beekeeper are the willows, dandelion, basswood (greenish-yellow), barberry, cucumbers, squashes, cotton, mustard, wild sunflowers, and goldenrods. The sensitive pea (*Cassia Chamæcrista*), or partridge pea, Mr. Baldwin says, is abundant in the high pine lands of northern Florida. "In summer the woods are yellow for miles with it, as far as the eye can see."

Waldoboro, Me.

IS THE LANGSTROTH FRAME TOO SHALLOW FOR SUCCESSFUL WINTERING?

BY SAMUEL SIMMINS

Mr. F. P. Clare appears to lay more stress upon the size than the depth of this brood-frame, March 15, p. 179. If it can be proved that the Langstroth is too shallow, then it will be considered that it is too small for the most profitable work. Many frames may contain the same equivalent in square inches, and yet all are not suitable for the best methods of management.

The depth of the puny British standard frame was largely a matter of working with nine-inch lumber. A similar consideration (apart from encouraging bees into badly furnished supers) appears to have ruled the construction and large adoption of the Langstroth frame.

Editor Root seems to have tried for something deeper than the Langstroth; but he states that he was nonplussed by a difficulty in procuring lumber of a suitable width. Thus, again, greater permanent efficiency was sacrificed to mere initial convenience in construction. Mr. Clare also falls back upon this same lumber difficulty.

Why did Dadant discard the Langstroth frame? Think of it! The very man who

extolled and revised Langstroth's book saw that he was losing dollars daily because the Langstroth frame was too shallow. He used them for twenty years, side by side with deeper, larger frames, and finally discarded the Langstroth for the sufficient reason that he wanted to lose no more dollars.

To use Mr. Clare's own expression, "laughable, is it not?" One can imagine Mr. Dadant smiling all over his face when he had finally destroyed those shallow brood-frames, and realized at last that he was going to lose no more dollars over those shallow frames.

Why did another very able beekeeper, Mr. Eddowes, of Jamaica, prefer to use the 16×10 frame rather than the Langstroth? Here are his own words: "My son tried the British standard in the Argentine and the Langstroth in Jamaica, alongside the Conqueror with 16×10 frames, and found them (standard and Langstroth) *nowhere*." The 16×10 frames gave him 330 lbs. per colony, while the shallow frames yielded 150 lbs., and, as he says, "with more trouble to look after the latter." "Laughable, is it not?" that a man should prefer not to lose 100 per cent by working with a frame too shallow.

Mr. Clare appears to have got a bit mixed as regards the population of a double 16×10 brood-chamber, resulting in the production of many useless bees too late to be any good. He is right off the track when he reasons that way. Certainly the double chambers should be filled with brood in the early part of the season.

Thereafter, the workers from such queens will see that there is never a surplus of useless consumers at the finish; and if they are worked for comb honey it will be the owner's fault if more than one brood-chamber is left when supering. The method he employs in utilizing the second chamber for plumping the working stock will gauge his own ingenuity.

Do I know of queens that will fill two 16×10 brood-chambers at the fore part of the season? Yes, friend Clare. I produce no others. Of course no practical beekeeper denies that one of the first essentials for ensuring successful wintering is an abundance of good food. But surely Mr. Clare knows that there are some half-dozen other very necessary conditions equally, if not more, essential.

Editor Root thinks if the writer were more acquainted with general conditions he would not consider the Langstroth frame out of date. Was Mr. Dadant unacquainted with general conditions of apiculture in the United States when he discarded the Langstroth frame, because he was losing hard cash by it daily? Was Mr. Eddowes acquainted with general conditions, with experience in the Argentine and Jamaica, when he found the Langstroth frame could be beaten hollow by another of scarcely more square inches, but so constructed as to give decidedly better results?

Was our mutual friend Editor Root acquainted with general conditions when he

tried to persuade beekeepers to use a deeper and larger frame than the Langstroth, or was there not at the back of his busy brain a practical development that assured him all was not right with the Langstroth frame?

Ultimate and permanent utility has been sacrificed to initial convenience through the supposed difficulty in procuring wider lumber than ten inches. Is this not a delusion? The writer has used only eleven-inch lumber for more than 30 years, and this has come almost wholly from North America, principally from Canada? Of course, it is a mere toss, pitching those logs over here; but it is strange that my friends can not catch a few of them. "A little extra cost!" Oh, yes! but compare that with 20 years greater efficiency.

Heathfield, England.

[The point at issue, apparently, between Mr. Simmins and ourself is that he believes that a large frame is more efficient than a small one, while we contend that efficiency lies in a large colony with the right proportion of fielders and nurse bees. We have tested both large and small frames, have compared hundreds of reports, have traveled all over the United States, and our conclusion is that there is no particular merit in a large frame, but there is merit in large powerful colonies, whether on large or small frames. Mr. R. F. Holtermann, one of the best beekeepers in Canada, has decided there is no advantage in the ten-frame Quinby over the twelve-frame Langstroth—a hive that has practically the same cubic capacity; and while we do not advocate twelve-frame Langstroth hives nor the ten-frame Quinby, we do believe that in the production of extracted honey there are times when neither the Quinby nor the twelve-frame Langstroth will be large enough. Therefore it follows, sometimes, that a good queen will utilize two ten-frame hive bodies of Langstroth depth. When the season closes, the single hive is quite large enough.]

For the production of *comb* honey the ten-frame Quinby or a twelve-frame Langstroth is too large for this country. Our authorities are practically a unit on this proposition. And right here, friend Simmins, do not forget that we said if you were more familiar with general conditions in *this country* you might change your mind. We did not say general conditions the world over, as you quote us. You ask, "Was Editor Root acquainted with general conditions when he tried to persuade beekeepers to use a deeper and larger frame than the Langstroth?" Here, again, you misquote us. We shall appreciate it very much if you will tell us *where* we ever advocated the big frames to the exclusion of all others. As editors of a publication that is going to people of all shades of opinion and diverse conditions so far as locality is concerned, we have put the Quinby frame and the divisible-brood-chamber hive with their shallow frames before the public, and have tried to let the

public decide on their merits. We have never advised the shallow frames to the exclusion of *all other* frames. As we have said of all frames, each has its own special advantages in certain localities. See our catalogs for a statement of the comparative merits of each size and style of frames. As a matter of fact, our experience teaches us, and reports confirm it, that a divisible-brood-chamber hive, on account of the horizontal passageway between two sets of frames, will winter bees better than any other form of brood-chamber; but the everlasting nuisance of handling a lot of little frames has practically driven the divisible brood-chamber out of the market—not because Editor Root advocated or condemned it, but because the beekeeping public has found it wanting. As we said before, the Langstroth frame has held its own everywhere in the United States. We are not contradicting the experiences of the Dadants; but we do believe that an equal capacity of hives and smaller frames would give just as good results.

It would be well to bear in mind that the Dadants are producers of *extracted* honey, or at least were at the time they introduced the Quinby frame into their apiaries. If we are correct, their large following in Europe are largely extracted-honey producers or producers of chunk comb honey. There is no question that the Quinby gives excellent results for the production of such honey; but we doubt very much whether the ten-frame Quinby would do any better than a twelve-frame Langstroth. Indeed, we believe that a sixteen or twenty frame Langstroth hive in two stories, in the production of extracted honey, would excel either.—ED.]

Will it Pay to Cut Down Maples and Plant Basswoods?

Dr. C. C. Miller:—Alongside the roadside of my place I have 40 rods of very large trees of hard maple, soft maple, and catalpa, which I am thinking of cutting out and replacing with basswood. Would you consider the basswood better for bees than any of the above which I now have? I could make good firewood of them, and plant something better for bees. Any information you could give me would be very thankfully received. Do you know where I could buy linden trees? When is the best time to sow white clover?

La Fayette, Ind.

W. H. ROBINSON.

[Dr. Miller replies:]

No other tree that will grow in your region compares with linden (or basswood) as a honey-yielder. However, it depends upon circumstances whether you will lose or gain by substituting lindens for your large maples. I never tasted a sample of maple honey, and probably never will. Yet I count maples of much value to me, since they come early and greatly help brood-rearing. Here's about the size of it: If there are plenty of other maples within a mile or so, and lindens not very plentiful, then you will gain greatly by making the change. If no other maples are in reach of your bees, then you would likely lose by the change. If no other maples are in reach of your bees, then you would likely lose by the change; for when early pasturage is scarce, a pound of honey in April may be worth more than ten in July.

You can get lindens from the American Forestry Co., South Framington, Mass.

White clover may be sown almost any time, as good a time as any being in the spring when farmers in your vicinity sow red clover.

Heads of Grain from Different Fields

Cause of European Foul Brood Unknown.

There was a time when I thought we knew that foul brood was caused by a certain bacillus (*alvei*). Then later *Bacillus milhi* and *Bacillus brandenburgensis* came in for a share, and were accused of being the mischief-makers, and possibly some other bacilli were talked of. I lost track of just what culprit was blamed most. It is a little surprising to me to note that Dr. Phillips, on page 88, Feb. 1, admits we are so at sea as to the bacillus that causes us so much trouble. Of course I realize that there must be several different causes for different diseases, such as European and American foul brood; but it seems to me that those who are familiar with microscope work and making cultures ought to be able to locate the chap and to ascertain the facts.

In the instance given on page 88, the prime swarm of Geo. Stephens may have issued with a virgin queen. There would be nothing strange about it, and I can see no evidence that this did not happen. I can not conceive of weather so unfavorable that a prime swarm could be held back six or eight successive days. It is just as true now as it was years ago, that the prime swarms appear after the first queen-cells are sealed. In practicing the Heddon method of preventing after-swarms, we depend on this.

Naples, N. Y.

F. GREINER.

[Referring to the cause of disease as mentioned by Dr. Phillips, page 88, I may say that the cause of American foul brood has been definitely determined as *Bacillus larvae*; but the cause of European foul brood is not known. While it is difficult to locate the organism, as Dr. Phillips says, of American foul brood, there is no trouble on the part of a bacteriologist or one who knows how to make pure cultures.—ED.]

Reflections on Beekeeping, Past and Present.

The writer remembers with what naive confidence he started in, as a boy, to manufacture honey in a couple of A. I. R.'s chaff hives—the kind he made along in the '80's. The only difficulty he encountered was that the bees refused to enter the section boxes of the upper story with business intent. Well, other work called him, and he was absent for ten years. When he returned, there was a surprising amount of honey stored, and, needless to say, he enjoyed it, notwithstanding the inconvenience of tearing the hives up to get the sweets. So our venture into the realms of apiculture ended in something like disaster, and we have concluded that beekeeping is a rather perilous calling, not to be entered into without considerable prayerful thought, and the genius of common sense.

After a lapse of 25 years we were prepared to find that giant strides had taken place in the art; but what, in reality, has occurred? Merely this: the fraternity had changed to the eight-frame hive, and then changed back again, like the king of France and his ten thousand men. Is there a lack of imagination somewhere?

Well, the erosion of the ages wears away the tooth of time, or something like that. Let us study the virtues of the bee in connection with the faults of mankind; and if humanity must go to the wall, let no guilty man escape. One thing is certain—men will eat honey in whatever form, if they can get it. If Mr. Bee objects to working in section boxes, it is evidently a case of a round peg in a square hole, and we should try hard to give him a square deal or a round hole as the case may be.

Medora, Ind., Oct. 23.

H. B. TURRELL.

Honey Butter; What it is and How it is Sold.

There has been some discussion about honey butter and candied honey in cakes often called by this name. However, as we understand it, honey butter is made from granulated honey and pure butter mixed in the proportion of one pound of butter to three of honey. If thoroughly mixed together, a spread is produced that many like, children especially. The best white-clover honey and the best grade of creamery butter should be used.

This product can be put on the market in a carton the same as butter, or in a wide-mouth glass jar, and sold at the same price as butter. There is

good money in it, for the three pounds of honey at ten cents and the one pound of butter at thirty cents cost only sixty cents, and yet the four pounds of the mixture will bring \$1.20. The price can remain fixed, or it can be varied like the price of butter.

Although honey is a preservative, the mixture will have to be handled as carefully as butter, as it is likely to become rancid and strong just as butter does if neglected.

One good feature about honey butter in winter is that it is always easy to spread. If desired, it can be labeled "Pancake Butter;" but the exact proportion of each ingredient must be stated on the label in order to conform to the pure-food laws.

Owosso, Mich.

NORMAN F. GUTE.

Do Not Apply the Stings to the Particular Joint Affected by Rheumatism.

Will you allow me to caution G. Prentice Carson (and perhaps others who may wish to try stings for rheumatism) against applying the stings upon the parts directly affected, as he suggests on p. 82, Feb. 1. My own experience has taught me that it is better to apply the stings to some other part of the body, and to let the virus work through the system gradually.

Rheumatism attacks me, at intervals several years apart, in the back and legs, and I then take "a course of treatment," applying a sting to each wrist every day for about ten days, after which I am free several years again. I learned of the cure by accident, through handling bees, after having been unsuccessfully treated for several months by a good physician.

In one of my attacks I tried applying the stings to the joint of my right knee, which was giving me a great deal of pain. As a result of that direct application I lay in bed for five weeks, unable to turn over without help. I am a firm believer in the good results to be obtained from the stings, but have never again tried the application to the spot affected. My experience of about 35 years also inclines me to the belief that the effect of a course of treatment disappears in about seven years, the time in which doctors tell us our bodies are renewed.

Frankfort, Kan., Feb. 8.

REV. L. P. HOLMES.

An Experience in Introducing by the Direct Method.

On Oct. 12, 1911, the writer dequeened a colony, and by the direct method ran in a queen which was about six weeks old. She had been kept in a small nucleus, and had been caged for three days prior to the above-mentioned introduction. When looking up the old queen, a queen-cell was found from which a queen had emerged within a few weeks. The queen, when found, proved to be a young one, and laying. The bees were dark hybrids, and very irritable. Robbing started whenever a hive was opened.

The following morning a dark queen—old but apparently not very aged—was thrown out from this colony. The newly introduced queen was found to be quietly at work. What would have happened to her had she been put in by the cage plan?

Providence, R. I.

ARTHUR C. MILLER.

Ten and Eighteen Frame Hives.

We notice that an eight-frame hive is in favor in your country. That size would be of no use here, because it would arouse the swarming propensity, which in out-aparies is such a nuisance. Hives holding from ten to eighteen standard frames are generally used, but the ten-frame hive with a couple of division-boards is really the most useful type of hive. It is usually doubled-walled, back and front, and the dummy boards make it double-walled at the sides. With plinths, and painted three coats, and the roof covered with thin flat galvanized iron over a thick layer of paper, this hive is warm, and absolutely waterproof. We have our own non-swarming system, and rarely have more than one swarm from a hundred colonies. We envy you your succession of honey crops, as you appear to have several harvests of honey in one season. C. CALVERT (Certificated Expert).

Cheltenham, Eng., Feb. 23.

The Beekeeper and his Hired Help.

I have never read any thing in GLEANINGS about hired help; so it may be of interest to some to give my experience. When advertisements appear in the bee journals they often contain a restricting clause something like this: "Users of liquor and tobacco need not apply." This I am pleased to note, for I always did and always shall oppose the use of liquor and tobacco. But to return to the beekeeper who employs an assistant. What does he do? Well, he tries to get out of his help all that he possibly can for the least money, with work every day, on Sundays, and even on the most important holidays. Then he engages some local help, which is easily done when the busy season is not yet at hand, and the work is not so hard and rushing, but when it is very much more interesting.

The employer seems to care little or nothing about the local man's using tobacco, for he puts him to work with the bees, and keeps his regular help at shop work, when he ought to be (according to the agreement) working with the bees and not all shop work. Shop work is all right. It is very nice and pleasant when there is nothing else to do; but working with the bees is by far more enjoyable.

Now about the salary proposition. We agreed on certain wages, including board and room. I had to travel 2000 miles to reach my destination, and all was lovely and well at the start. After the first month or so the employer found that the landlady at whose place his assistants got their daily bread charged too much for board, and accordingly informed his humble servants that they must change to another boarding-place, which we were willing to do. I say *we*, for there were two of us—myself and a fellow worker for the season, both treated alike. Upon finding bedbugs in the new place we both frankly refused to change, as there were enough of the vermin in the former place. Our first landlady was already making war and a desperate battle on the bugs, and succeeded in getting them pretty well exterminated. Bedbugs may be all right for the class of people who never knew what it is to be without them, having been brought up and raised with them, but we didn't happen to have been brought up that way.

Being unwilling to stay at the new place we had to pay the difference in the price of board. Right here I want to say that all beekeepers contemplating engaging future and necessary help had better make preparations before their employees arrive, and thus avoid hard feelings, or else keep their advertisements out of the papers, for some of them don't intend to live up to their agreement in the first place.

Then the likes of two bosses on one bee-ranch sooner or later prove irksome and menacing, and causes continual trouble. Throughout the whole season the boss is tearing hives apart, and his assistants are to take care of them and put them together again. By so doing some severe cases of painful stinging are encountered, which could have been dispensed with by each individual taking care of certain hives alone. In working alone at certain hives one takes more pleasure and interest in the work, and also accomplishes much more in the end.

I am not an amateur at beekeeping, neither am I boasting of myself as a professional in the ever-instructive art of the apiary. I am only giving a brief article on my last year's experience in working on an extensive bee-ranch on a large scale, with about 1000 colonies.

Lake City, Minn.

E. A. KRINKE.

Splicing in Pieces of Worker Comb where Drone Comb is Cut Out.

I am cutting out all the drone comb I can find. Where there are corners or where the lower half is drone, I am cutting that out and taking other worker comb, cutting pieces to fit where the larger cells came out, and filling in with it. It has been my experience that bees will rebuild drone comb if not replaced.

Crestline, Ohio.

M. F. SOULE.

[It has been our experience that if the combs contain any great number of drone cells, they had better be rendered for wax; for even if worker comb is substituted in the space made vacant by the drone comb removed, it will always be a patched up affair and there will be a good many drone cells along the line of intersection of the two pieces. However, if there is only a small amount of the drone comb in the corner say, it undoubtedly pays

to cut it out and put a piece of worker comb in its place. As you say, if you put in no worker comb, the bees are likely to fill in with drone cells.—ED.]

More About the Census Figures in Regard to Beekeeping.

I note what is said, p. 259, May 1, concerning the United States census and bees. I was a census enumerator in 1910; and, while we had no instructions to gather statistics of bees not kept on farms, we were to take statistics of every colony kept on farms. By the census rules, three acres constituted a farm. I think Mr. Coburn is slightly wrong about the necessity of the product amounting to \$400 before the apiary would be considered in statistics.

I agree that the statistics of the bee industry are not reliable, inasmuch as no count was made of bees in towns. However, the same condition holds true of the poultry industry.

Allenville, Mich., May 4,

W. K. PALMER.

Another Reason Why the Census Figures were not Accurate.

I have read the editorial, May 1st, about the last census of bees. Let me tell you how it was taken here, or, rather, *not* taken. My mother, a widow, was at a neighbor's when the census man called there. He asked her to give in her list then, and she told him that she could not give him an accurate list, as we boys ran the farm and he would have to see us about the stock, etc. He never called, and some of us were at home all the time. He told my brother in town it did not matter much, as he always put down what he thought was right. I don't know he knew what was right. At that time I had 110 colonies of bees. He did not know that I kept bees, so none of these were listed. I know of several other small beekeepers who are farmers, who were not asked about their bees. I feel sure that not over 25 per cent of the bees in this (Bath) county were numbered. Is there any wonder why beekeeping has declined (in figures) so long as census-taking is only another pie-counter for the politician.

Sharpburg, Ky.

RAYMOND SMATHER.

Swarm, Swarm, Swarm.

I think I can beat Mr. E. A. Day, page 280, May 1. I had a colony of bees in a log gum which cast a prime swarm April 22. I hived them on one-inch foundation starters, and they began to draw out the cells, but swarmed out and left the next day. A second swarm issued from the parent hive on May 2, but returned without clustering. They issued again May 3 and clustered, but returned before I could hive them. At 8 A.M., May 4, they came out again and clustered. This time I succeeded in getting them into a new hive, but they returned to the old one in less than half an hour. At 11:30, the same morning, they came out again and clustered. I hived them again, and they have been working nicely ever since.

On May 5 a third swarm issued from the parent colony and clustered, but returned in about 20 minutes. May 6 they swarmed out again about 8:30 A.M. and clustered. I was working about a mile and a half from home, so they had to hang on the bush until I came home to dinner. Just as I was preparing to hive them they let go the limb on which they had been all the morning, and left for parts unknown.

Huntsville, Ala.

H. M. WEBSTER.

That Swarm that Did Not Cluster.

In my experience with bees of over sixty years, I have never known a swarm to issue and leave without clustering unless they had previously issued and returned to their parent hive, p. 284, May 1. In this case, sometimes the queen will be unable to fly; and, not returning with the swarm, the bees will issue later with a virgin queen. Such swarms are always very large, as hatching bees are added until the swarm is ready to reissue with a virgin queen. In this case of Mr. Grams the bees no doubt had previously swarmed and returned to the hive, and in the interval had sent out scouts and located that tree.

South Bethlehem, N. Y.

G. J. FLANSBURGH.

[See what A. I. Root has to say on this subject, p. 306, May 15.—ED.]

Our Homes

A. I. ROOT

Charity suffereth long and is kind; . . . doth not behave itself unseemly; . . . seeketh not its own; . . . thinketh no evil; . . . beareth all things; . . . endureth all things.—1. COR. 13 : 4, 5, 7.

You will notice, friends, that our text is right along the line of that extract I made from the *Sunday School Times*, page 287, May 1, in regard to avoiding criticism. Love was the central thought of that extract, and divine love is the central thought of our text. Now the question has come up, and has been discussed, as to how far this great charity or love could be applied to the events of every-day life. There is one thing that should be considered, both in the clipping from the *Sunday School Times* and in the text I have chosen. Where we personally are concerned, and nobody else, the chapter is all right; but where the wrong-doer is injuring somebody else, or community at large, it is our duty to step forward and make trouble—yes, if need be make *war* and *encourage* war. The man who is making counterfeit money should be stopped at once, no matter what trouble it makes to do so, even to the extent of the loss of life; and I hope you will not quarrel with me if I say the liquor-traffic should be regarded in the same light. But for the present I wish to apply the beautiful text to a trip of 48 hours from Bradentown, Fla., to my home here in Medina. Mrs. Root could not stand the hot weather in Florida until May 1 as I had planned. She was so anxious to get back home among the children and grandchildren that she urged me to start as early as April 16.

As we had previously had trouble in securing lower berths for travel, I went to our agent two weeks ahead, and asked him to make application for a berth in the sleeper. He said three or four days ahead of the time would be ample to make sure; but as he had once before disappointed us I urged him to make application about a week ahead of the time. The great bulk of travel back to the North is during April, as you may be aware; and a great many times there is difficulty in securing a berth. I gave him my ticket and told him I would like some document to show that the berth was secured. As we got on the train I went to him for my reservation, when he gave me a copy of a telegram, which, although I did not understand, I supposed to be all right. When we arrived at Jacksonville, however, the agent said my telegram referred to another road, and asked if the agent at Bradentown had my *ticket* when he made application. I assured him he had my ticket in his hand, and looked it over carefully. There was barely a chance to secure an *upper* berth on the train that was almost ready to start. Let me explain here that, although much has been said about going to Florida to escape the grip, they *do* have it in Florida as well as here in the North—sometimes in a

very aggravated form; and this was the case during the past winter. It seemed to be a sort of epidemic that went all through neighborhoods and perhaps towns. Mrs. Root was just recovering from a severe attack; and she said she did not see how she *could* climb away up into the "loft," for we had tried it before under the same or similar circumstances.

Our sleeper was crowded, and nearly if not quite every upper berth was occupied as well as every lower one. As it came time to retire, Mrs. Root said again she did not see how she could get away up there "under the eaves." The porter said there was not any help for it. All the lower berths were secured a long way ahead. Although it is comparatively common, I hesitated about going to an entire stranger and trying to get somebody to consent to make an exchange. I can not remember exactly, but I think my little prayer, "Lord, help," must have welled up as it almost invariably does when I am in trouble.

Let us pause a minute right here. Was it *my* duty to inform the Seaboard Air Line that their agent at Bradentown had *twice* gotten us into that predicament? In accordance with the spirit of our beautiful text, should I have remonstrated, or just let the matter drop? Charitably considered, it is almost impossible to travel without having more or less of these perplexities. While I was meditating a beautiful bright woman (and, by the way, what is there in this world of ours so bright and inspiring as a handsome woman in the full bloom of life and health, showing forth the spirit of the good Samaritan?) came to us and said, "My good friends, the berth below your own was to be occupied by our two little girls. Now, they are young and spry, and can easily get up into the upper berth, and they will not mind making an exchange, especially as you are elderly people."

Two handsome children seconded their mother's offer, and said they would just like the fun of climbing "upstairs;" and pretty soon their father, one of God's noblemen, like his wife, lifted them up into their sleeping compartment with much fun and frolic. We not only thanked our new kind friends, but I, at least, thanked God mentally for such quick and swift deliverance. Now let me explain.

Just as soon as the train started, the porter commenced at one end of the car to make up the berths. As we are elderly people I asked him if he could not skip along to ours, inasmuch as many of the passengers were in no hurry to go to bed. He said he could not. They had got to be taken in their turn. By the way, this porter, although he was a great stout muscular fellow, looked to me as if he was tired out when we started. Perhaps half a dollar would have enabled

him to change his mind; but I am most emphatically opposed to that kind of discrimination. Not only millionaires but men of moderate wealth are accustomed to being put ahead of common people by the aid of their money. I am glad to know there is a strong movement of late to do away with this whole "tipping" business. Well, the porter did not get to our berth until pretty well toward midnight, and Mrs. Root was very tired. Finally, when our berth was ready and the little girls sleeping soundly in the berth above, we were ready to retire. We were down in the region of hot weather, mind you, and the porter objected to more ventilation because the most of them did not want it. You know how Mrs. Root and I sleep—doors and windows wide open, no matter where we are. Just as soon as Mrs. Root got into her berth she said she could not *live* in that hot place—there would *have* to be a window open. After exhausting my strength without avail I applied to the porter. He replied he could not open the window and put in a screen for *anybody* until the berths were all made up. Should I have given him half a dollar, as in the case before? I was undecided, and I was urging Mrs. Root to put up with the bad air until the porter had got the rest "put to bed." She said she would much rather sit up all night than to stay in that hot place without any fresh air. I think my little prayer rang out again (like an alarm clock, as I have told you), "Lord, help!" and help came so swift that I was really startled (as I have been so many times before) at the prompt answer to my prayer for deliverance. A baby's cry diverted the attention of the crowd that was hustling to get to bed and to sleep. If there is any thing in this world that will rouse up Mrs. Root, and bring forward her best qualities, it is a baby's cry. She soon found out that it belonged to a young mother. The young mother was car-sick, and she, like ourselves, had been assigned to an upper berth, as there was no other. Now just listen. I had been trying to *persuade* Mrs. Root, ever since we had been assigned an upper berth, that the air was better, and I could manipulate the ventilators myself, etc. But she stoutly objected. When, however, she found out about the baby belonging to the sick mother, to be put upstairs, when she was already vomiting, our own lower berth was placed at their disposal in an instant; and Mrs. Root smilingly assured the mother she did not mind climbing up at all; in fact, that she was *glad* to make the exchange, which was true. Sometimes a little of that "love" for humanity we have been considering enables us to change our minds and "opinions" very quickly. Our new berth upstairs was about the last one to be made up. We did not get to bed until about midnight. I noticed the passengers had been climbing up without the usual step-ladders. When I asked the porter if there was not a step-ladder to enable Mrs. Root to get above he replied, "Sure; it is

back at the other end of the car. If you want it just go and get it." You see the "half-dollar" came into view *again* just here. I started to go for the step-ladder, but a bright young woman (dear me! what glimpses of sunshine these *handsome* women do occasionally bring to this world of ours!) got past me, tripped to the back end of the car, got hold of the big step-ladder, and came rushing with it up to Mrs. Root, laughing in a roguish way as she did so, because she had "turned *porter*" for the time being. As I noticed her beaming smile, with a little heightened color from the exertion, I thought she was about the handsomest woman I ever saw—*except* Mrs. Root when she was a girl of about the same age. Now lest you criticise too severely that particular porter, listen to what Ernest said when I told him about it:

"Father, don't be too severe on these porters. During the height of travel they are overworked. This fellow had probably been working night and day, and he was tired out to start with, and with that car crammed full of sick babies and sick women he probably had had no chance to sleep much, for several nights past."

When I got into that upper berth I opened the ventilators—I think there were four of them; and everybody else seemed to be too tired and sleepy to object; so Mrs. Root had a very comfortable night's rest after all.

Just as we approached Cincinnati our engine, on account of its great load of passengers, gave out; and instead of making connections so as to reach Medina next morning we were obliged to stay in Cincinnati over night. As the locomotive kept bothering, it was again about midnight before we got into the depot. As a rule I avoid patronizing any hotel that keeps a bar. Two difficulties stood in the way just then, however—the lateness of the hour, and the difficulty *at any hour* of finding a hotel in *Cincinnati* without a bar. As we came out into the street several asked us if we wanted lodging. One of the most gentlemanly-appearing men of the lot took us into a hotel near by—75 cents each for a comfortable room. As we passed through a neat dining-room I asked him how much more for breakfast. He said, "The dining-room is a separate affair. But you can have a lovely breakfast here, as early as you wish, for only 25 cents."*

A little after our usual time we sat down at a very neat table for breakfast. I noticed at once that there were full-sized plate-glass mirrors on each side of the room. The mirrors, being exactly opposite each other, produced the effect of a series of din-

*As we passed into the good-sized bedroom I caught hold of a large window the first thing to raise the sash. As it had evidently been undisturbed for a long time I failed to make it start, and appealed to our host. "Why" said he, "do you want the window open? Is there not a great plenty of air in a big room like this?" I submit this as a sample of the contracted ideas of a great part of the world. No wonder people are dying at such a rate that they keep the doctors busy in studying up names for "new-fangled" diseases.

ing-rooms as far as the eye could see on either side of this room. While Mrs. Root was joking about the "lovely" breakfast for 25 cents, the nice-looking fellow of the night before came and asked what we would have. I replied, "What have you for breakfast?"

He answered, "Any thing you want."

I replied that I would have a beefsteak, and Mrs. Root said that, as she was not very hungry, she would just have some bacon, with potatoes and bread that go with it as a matter of course. I remarked that my steak was rather better than one would expect for 25 cents; and Mrs. Root had some eggs with her bacon, which she did not order. When I came to pay the bill our host said, "Pay at the bar." And then I knew that this fine expensive dining-room belonged to a gilded up-to-date Cincinnati saloon that was just between us and the street. While I was watching the bartender and his assistant pour out drinks, the man of the "lovely breakfast" came up behind us and informed the bartender that our breakfast was \$1.20! Of course, I paid it, but I turned on him, and said, "My dear sir, didn't you say that your 'lovely' breakfast was only 25 cents?"

"That is true, sir; but instead of ordering the regular breakfast you ordered special things, and we served them at the regular price."

Moral.—When you go into a saloon for any purpose whatever, remember the proprietor does not obey either man's laws nor God's, and that you are *sure* to get swindled in some way or other before you get out.

Now, in my hurried narration of the above I have made but little reference to our beautiful text. Let us go back a little. What was my duty, as a Christian man—one who is striving to win souls to Christ every day of his life? Of course, the above is not true when applied to myself; but we will, for the time being, *suppose* it to be true. Should such a person complain of the agent because he attended to his duty so carelessly? Should he complain at headquarters of the porter*—that is, to obey the spirit of this text? And, finally, should he object to the unfair method of the saloon-keeper to get twice the price of a breakfast? In looking back at the matter I believe I did *about* the proper thing; but it may be, after all, I have erred; because if these persons who are remiss in their duties at their important posts receive no reproof nor rebuke, they will probably keep on doing the same thing over and over again. May God help us to choose the golden mean which will include all humanity as our neighbors, and to strive to love our neighbor as ourself.

*In justice to the porters of our various railways, let me say that I have never before found one so uncivil as this one. He was certainly an exception to the general run of his class. I noticed that, as we approached Cincinnati, when he took his brush-broom and went to the passengers one after another, only one man in that car saw fit to accept his services. He did not get the half-dollars he might have had if he had studied our text—"Suffereth long, and is kind."

I for one want to live in such a way that I can pleasantly shake hands with everybody I meet.

Some time ago I heard of a friend who had been educated for the ministry. He was a child of prayer—at least he *said* he was, and his parents spent much time and means in fitting him for his sacred calling. Well, when I saw an advertisement with his name appended, to the effect that *he* was agent for a gold-mine speculation, I wrote to him, remonstrating severely. I protested against the extravagant offers and promises (which he could not *possibly* keep) on his printed gold-mine circular. He thought I was rather severe. Some time afterward I suddenly came across him. I think he was present at a religious conference. I put out my hand to him, and, while looking him pleasantly in the face, said, "Mr. H., I am glad to see you; but I shall be gladder still if you can inform me that you are no longer urging people to invest in gold-mining schemes."

His countenance fell somewhat when he said he was still pushing that questionable work—questionable certainly for a professing Christian. But when he attempted to explain that Christianity and the circular he had been putting out were not antagonistic, I decided I could not give him any more of my time. I had done my duty. "Charity thinketh no evil." If I have been in times past too ready to "think evil" of persons or things, may the Holy Spirit rebuke and enlighten me.

CONSECRATED MILLIONAIRES; DR. CHAPMAN'S EVANGELISTIC WORK ON THE OTHER SIDE OF THE WORLD.

The following letter explains itself:

Mr. A. I. Root:—I am sending by this mail three copies of the *Outlook* containing reports of a mission that is being conducted on this side of the world by some of your countrymen. As you will see, great numbers are being led to Christ. Among them are our own three children. I feel sure, from reading your Home notes, that what is being accomplished here will interest you.

Green Island, N. Z., April 8. ROBT. H. NEILSON.

From the pages of the *Outlook* (published in Dunedin, N. Z.), as explanatory of this great revival I make two clippings. A reporter interviews Dr. Chapman as follows:

What relation had the John H. Converse bequest to the enlarged sphere of your work?

"Mr. John H. Converse, of the Baldwin Locomotive Works, of Philadelphia, was a wealthy Presbyterian layman worth ten million dollars, five millions of which he spent in religious and philanthropic work during his lifetime, and five millions of which he bequeathed to similar objects after his death. The bequest which I am entrusted to administer is to enable me to carry on evangelistic work in different parts of the world, and also to train up and send out suitable evangelists to carry on the same work that I am sent out to do."

Do you believe that, in the preaching of the gospel, is to be found the solvent for all social troubles? "Certainly." Every thing else has been tried and has failed. The preaching of the old-fashioned gospel and the teachings of Jesus Christ will be found sufficient for all the different problems that face us to-day."

May God be praised for such devoted men as John H. Converse. I have long wished

and prayed that some of the millions that often do harm instead of good might be used to spread the gospel. As nearly as I can make out from a hasty review of the copies of the *Outlook*, the conversions run away up into the thousands. Yes, let me say it most emphatically, the preaching of the gospel *will* be found the solvent of all of our political troubles, and it is also (most emphatically) the *only* remedy. While I

dictate, ex-president Roosevelt and President Taft, two men who have enjoyed the highest gift our nation has to bestow, are now engaged in filthy mud-slinging. God grant that our people may awaken from their mistaken lethargy, and decide that (if this continues) *neither* one of these men is wanted as President of a people who are proud to style this the "land of the free and the home of the brave."

POULTRY DEPARTMENT

A. I. ROOT

"LOCKING THE STABLE AFTER THE HORSE IS STOLEN."

On page 322, May 15, I made mention of 28 smart chicks, and said that not one of them had been lost up to the time they were two weeks old. Well, fully half of those 28 were three-fourths-blooded Buttercups. The way it came about, I selected from my flock a dozen laying hens, half Buttercups and half Leghorns, and gave them to my old full-blooded Buttercup rooster; and the 28 chicks were hatched from eggs from these selected half Buttercups. At least half of the 28 were finely marked Buttercups. As their wing feathers grew and showed the spots and the delicate pencillings, I thought that they were handsomer than the most gorgeously painted butterflies. In fact, I thought so much of them that I began to wonder if something would not happen to them while I was off to my northern home. I arranged with a near neighbor to look after the hen and the 28 chicks. They were put into a poultry-house where all openings were covered with poultry-netting; and the chicks were getting to be so lively with their wings that I expected them very soon to occupy little roosts about two feet from the ground. When I left, the chicks with the hen occupied a brooder box that had been out in the weather until some of the boards were getting to be pretty rotten. The day before I left Florida I planned to put inch netting a foot or more in the ground below the sills of this poultry-house, but I did not get at it. Now read the following letter:

Dear Friend Root:—Your letter came Saturday, and I was very glad to hear from you. Miss you? Well, I should say so! The ducks seem to be getting along nicely. They lay three eggs almost every day; two or three days we have gotten only two. Something got after the chicks. I did not know what; but they were so frightened that they did not want to go into the coop at night. I had to pick them up and put them in. Friday morning I found *four dead ones*. One was almost all eaten up, and one was hurt so it could not use one leg. Wife took it into the house and nursed it so it is almost well now. After that I shut them in, as I thought, securely in the little coop. This morning I went out to find them, and *every one was dead*. Almost all had their heads eaten off. Mr. Morgan thinks it is rats. He killed one rat among the ducks.

I shall put out some poison to-night, and see what the result will be. I feel very badly over it—more than if they were my own.

The watermelons are doing nicely, and I will hoe them out in the morning.

Bradentown, Fla., April 28. C. L. HARRISON.

Monday morning.—I got the culprit last night—a skunk. I "locked the barn door after the horse was stolen."

Oh dear me! I wonder if I shall ever learn to protect my chickens so there absolutely can *not* be any such mishap as the above. They had been having bread and milk and boiled eggs, and every thing that could conduce to their thrift. And just think of the time I spent, to get them past the danger period, and then went off and left them so a skunk could dig in the soft sandy ground and get under the sills, and then tear out the boards and mutilate and kill *every last one* of the 28! I have been feeling so sore and conscience-stricken ever since the above letter came to hand that I am seeking relief, and finally it occurred to me that I could get some satisfaction by warning others whose chickens were as yet safe and sound. What a piece of folly it is, any way, to waste feed and time and money, and then let some miserable "rodent" ruin it all! By the way, I was not aware that a skunk would kill a whole flock in that way. Is it not possible that it was the work of a weasel and not that of the skunk that *happened* to get poisoned? Of course no blame at all is to be attached to my good neighbor Mr. Harrison and his wife.

Do you want to know about the ducks I left? Well, here is a letter from Dr. Morgan's boy, scarcely twelve years old:

Mr. A. I. Root:—I thought I would write to you how the ducks are getting along. I get three eggs every day, but once in a while one of them skips a day. The ducks are almost all full grown, except the one small one in the bunch of the fifteen.

Papa got Mr. Raub's incubator and put fifty-two duck eggs in it. The ducks are real tame. Nobody has stolen them. There are still 30 of them.

I have five little ducks. I expect to have more before long.

Bradentown, Fla., May 7. REGINALD MORGAN.

By the way, it is, to me, astonishing that three ducks have kept on, winter and summer, giving three eggs almost every day. Will a flock of 25 or 30 do any thing like it? If nothing serious happens, I propose to answer the question next winter.

While I am about it I want to tell you of another lesson that I learned. I planned to carry 48 laying hens of a cross between Buttercups and Leghorns over to neighbor Abbott's; and as the weather was warm I had a wire-cloth cage made large enough to

take the whole 48. Now, this cage was ample in size, and well ventilated; but I forgot that it was to hold about 200 lbs. weight; and just as four men were lifting it on the wagon the bottom pulled loose. The chickens were all in a heap, tangled in the wire cloth, and some of them were near smothering. I can not quite remember; but I am sure my little prayer, "Lord, help," came up of itself. I managed to get hold of the break, or partly under it, and held it up until it could be slid over on to the wagon-bed. Then we reached down through the top and pulled the chickens one by one out of the snarl. Not one was hurt, and only two got out. When I sent them away, the 48 laying hens were giving close to 40 eggs a day, and I am anxiously waiting for reports from them after they have been carried a couple of miles in the shape I have mentioned.

Now, instead of a moral I think we will have two of them something like this: One-inch-mesh netting costs only two or three cents a square foot. If you want to have "fun and profit" in poultry-keeping, make your precious little chicks *absolutely* safe from midnight prowlers so you can go to sleep at night with a clear conscience. The second moral is, when you wish to put forty or fifty grown-up fowls in one cage, bear in mind that the cage must be strong enough to hold 200 or 300 lbs. weight.

Mrs. Root has just received a letter from Mrs. Harrison in which she says the little chick mentioned by Mr. Harrison has recovered all right; it is one of those beautifully marked Buttercups that I mentioned, so there is *one* left of the flock of 28, after all. She says it is growing finely, and is very tame and docile, and comes up every night of its own accord to be shut up securely so night prowlers can not possibly get it. She also writes us something about the ducks. For some time before I left, one of my largest flocks could scarcely be driven past a certain point in their canal. Thinking it was a queer notion or whim of theirs I would drive them up and almost push them along past that particular spot—see diagram of their canal on page 255. Well, finally, rather than walk past that particular point they would all take wing and fly over it one after another. I still thought it was just a notion, but was delighted to see them spread their gauzy wings and fly so easily, while it takes such a lot of ponderous machinery with great spread of canvas for humanity to "get up into the air." Well, this letter explains why the ducks were so averse to going past that particular spot where the bushy bank extended a little over the water. I quote as follows from her letter: "Mr. Morgan told me the young ducks seemed to be afraid to pass a certain spot in their path to go down into the water. On careful examination he found a nest of water moccasins. He now lets the ducks of all ages go together; in fact, they have grown so they are all nearly of a size."

I confess I have never seen a "water moccasin" in Florida; and as I have never lost

any ducks except those taken by the alligators, I think the ducks were more scared than hurt, and that was the reason why they would not go past their nest.

THE 48 LAYING HENS, AND WHAT THEY ARE DOING IN THE MONTH OF MAY.

Inasmuch as I have reported in regard to the small chicks and the ducks, I think you had better read the following from neighbor Abbott in regard to the 48 half Leghorns and half Buttercups that I left in his care.

Dear Mr. Root:—Your hens are in the pink of condition—a strong, active lot; but they are mixed up so with mine I can't tell you just what they are doing. Eggs are 20 cts.; wheat, \$2.40; corn, \$2.10; oats, out of sight. It would take far more figures to find the profits than to express it. We had a nice crop of potatoes; dug them in 70 days from planting. We are well, and have no trouble with cold feet. We were down the river the other day. A kingfish (that is, a mammoth mackerel), 4 feet and 3 inches long, jumped on shore, high and dry. I will send you a picture when I write again.

Bradentown, Fla., May 17.

D. W. ABBOTT.

HURRAH FOR THE INDIAN RUNNER DUCKS!

TWO EGGS IN ONE DAY, AND AN EGG
APIECE THE NEXT DAY, ETC.

Mr. A. I. Root:—I read with great interest what you write for your magazine. In the last issue, May 15, I notice that you speak of ducks laying two eggs in one day, and one of which is usually a soft-shelled one. Well, I have a few of the Indian Runner ducks, and will tell you some of my experience which may serve to mix up matters a little worse. I had nine breeding ducks and two drakes along a small ditch. They laid the following for a few days: 10, 9, 9, 12, 8. Your opinion is that, when they lay two eggs in one day, they miss the next; but these seem to have gone one better, and laid the following day. In quite a few other cases they have laid 10 per day. On the 9th of May a raccoon killed one duck, and since then one day I got nine eggs.

Here is something I accidentally found: If your ducks are ever reluctant to lay, try this: Take a pail that has had tar in it, and make ducks drink their water from this. It seems to have helped in my case, and I wish you would see if it is good.

Bryan, O., May 21.

CARLTON OPDYCKE.

Why, my good friend, your letter is one of the most "interesting" I ever got hold of. The information that two Indian Runner ducks laid two eggs each in one day, and then an egg apiece the day after, is a wonderful piece of news; and if such reports can be duplicated we may unite in thanking the great Father above for giving us more eggs, better eggs, and for a smaller sum of money, than the world has ever had before. In regard to the "better" eggs, I for one think I would rather have a fresh egg from an Indian Runner duck that has been "corn fed" than any other egg I ever ate.

INFERTILE EGGS; HOW MUCH HAS AN INCUBATOR TO DO WITH IT?

This matter is discussed on page 147, March 1. On page 256, W. C. Ellerin, of the Cyphers Incubator Co., has something to say in regard to the matter. Now, I am pleased to note that so good an authority as L. E. Keyser, of the *Western Poultry Journal*, backs me up as follows:

It is a fact that a good sitting hen will often hatch eggs that will not start in an incubator. I once placed a number of infertile eggs that had been

tested out of an incubator on the third day under a broody hen, thinking to give them to her for a short time only, and see whether she really meant business or not. I did not receive the eggs I intended to place under the hen, and no more attention was paid to her. What was my surprise when, at the end of about three weeks, she came off with three chicks! There were eight eggs in all, and I at once examined those remaining in the nest. Four were still clear and one rotten, showing that it had started to develop.

The above is a stronger corroboration of the superiority of the sitting hen than I had thought of or expected to get. Once more, what have the venders of incubators to say to it? And in order that this may be further tested, can we not have reports from eggs pronounced infertile by the incubator, say in five days, and afterward submitted to a sitting hen? This once more strongly

suggests the idea of starting all the eggs under a sitting hen and letting the incubator finish the hatch. It would not be so very expensive to put all the sitting hens found on a large poultry-farm in a room by themselves; then give these sitting hens, all at one time, enough eggs to fill the incubator, or rather more - say enough to furnish fertile eggs to the capacity of the incubator. If there should happen to be a few more, let one or more of the hens finish them up; and in this way I think we might easily get a hatch of 90 or even 95 per cent, and probably avoid, at least to a great extent, "dead in the shell." As I have said before, this plan is one of the big secrets in the book "Poultry Secrets," from our good friends of the *Farm Journal*.

FLORIDA LAND SPECULATIONS, ETC.

Our readers are well aware that I have been holding up warnings against the schemes of land speculators for years past, or ever since I have made my winter home in Florida. I have again and again urged that no one should think of investing unless he has been on the spot, seen what he is buying, and made inquiries of old residents not having land for sale. Under the circumstances the following brief letter from an old friend of GLEANINGS comes as a surprise, and I confess it was not altogether a pleasant one:

A. I. Root:—In GLEANINGS for April 15 I find in an advertisement these words: "Low-priced lands. Easy terms. Plenty of water. Healthful climate, in the land of Manatee, on west coast of Florida. Net \$500 to \$1000 per acre." For shame! With all your boasted religion and pretense of a clean life, for the paltry amount you get for this advertisement you can stretch your conscience so as to insert this in GLEANINGS. Do you suppose such an advertisement as this would be inserted in the *Rural New-Yorker*? Never. The net amount stated is a bald lie, and is intended to deceive. Why, if people generally could be made to believe that statement, there would not be an uncultivated acre of land (or, rather, *sand*, for that is what it is) in Florida in a year's time. I have been in Florida, and know just what it is. Take the advertisement out.

White Hall, Ill., April 19.

A. W. FOREMAN.

Permit me to thank you, my good friend, for your interest in the good name of your old friend A. I. R., and GLEANINGS also; but were you not a little hasty when you wrote the above? What you quote comes from the advertisement of the Seaboard Air Line Railway Co., and they have been our regular advertisers for years past; and I can not remember that we have ever before received any objection to the way in which they word their advertisement. In fact, I have many times advised inquirers to get and read their literature. The matter has been so much discussed in the pages of GLEANINGS that I will need to go over it only briefly.

As you say, the greater part of Florida is really sand; but if you will visit my Florida home in Manatee Co., I think I can astonish you by showing you what my neighbor Rood, right across the street from our place, is doing and has been doing for years. He

has some excellent land that was formerly a sort of pond. It is now thoroughly underdrained, and also equipped with an artesian well to furnish water in times of drouth. Furthermore, in addition to neighbor Rood's horses used on his forty acres, he keeps quite a few Jersey cows, and sells milk; and he grows his own hay, and I guess the greater part of his feed for cows and horses. Let me say now right here that these Jersey cows are kept mainly, if I am right, for the manure; and his horses and cattle are kept in stables such as we have here in the North. Besides the stable manure, he buys load after load of commercial fertilizer.

You object to the statement in GLEANINGS of \$500 to \$1000 per acre. Well, Mr. Rood, during the past winter, if I remember correctly, received over \$2000 for the celery grown on a single acre. After the celery was off he planted potatoes; and when I came away he had about as handsome a stand of potatoes as I ever saw. The fertilizer put on to grow the celery was all that was needed for the potatoes. They did not have a cent's worth more. The potatoes will soon be dug, and in their place will be put tomatoes or some other crop. He has been getting three big crops off the same ground year after year. And this is not all. Besides his reclaimed swamp he has some poor sandy land on higher ground. I supposed this pine land would not yield enough to pay, even with his skill and experience; but while I have been living there, and could watch operations, he cleared off that high and dry pine land, got out the stumps, worked it up thoroughly, put in tiles, put down an artesian well, and, much to my surprise and astonishment, he has this year taken off almost as good a crop of celery as from his reclaimed swamp. Of course it has cost a lot of money to do it, and it took a man like Mr. Rood to make a success of it. When I asked him what amount of fertilizer he put on that new land to get such a quick response, he replied smilingly that he put on all he could afford to, and then shut his eyes and put on some more. I ask

ed him if it exceeded three tons, costing about \$40.00 a ton. He said he felt sure it would not be so much. But when buyers from the North came and looked over his crop they offered him something like \$1000 for the celery on that poor unpromising piece of land. (See GLEANINGS page 289, May 1st issue.) You say you have been in Florida. You had better go back there, my good friend Foreman, this present year of 1912, and see what is going on. I think there is plenty of land, perhaps, however, not near to market or transportation, as good as Mr. Rood's, that can be bought for from five to ten dollars an acre; but it needs *means* to develop it, and a live man like Mr. Rood to direct matters. Besides what Mr. Rood is doing, and some others like him, there is a general stampede to Manatee Co., as I have told you before. Houses are being built, and roads and cement pavements being constructed in and around

Bradentown, at a rate almost unprecedented.

Finally, whoever sends for the literature sent out by any railroad company building railways through a new and undeveloped region, should, of course, understand that the railway companies present in their literature the *possibilities* of that region rather than the rule.

Perhaps it would be well to say in closing that there are all the time unfortunate individuals who start in to do as Mr. Rood is doing, and who make a failure of it, and some of them declare that there is more money thrown away in Florida trucking than is ever made out of it. But, my good friend, it is true that this same thing is going on all over the North as well as the South. Where one succeeds, there are many more who make failures, especially if they do not have a genuine love for the business aside from its financial possibilities.

Health Notes

BY A. I. ROOT.

"PREVENTION BETTER THAN CURE."

I think it was the *Scientific American* that said, recently, great progress has been made in recent years in preventing sickness, suffering, and death by means of improved sanitation. Many of us can remember when typhoid fever, diphtheria, scarlet fever, smallpox, etc., had to have their run. Sometimes the "run" took a whole neighborhood or a good-sized village, and not only incurred fearful doctor-bills, but sent a lot of people to the cemetery; and the *Scientific American* added that the greatest achievements in medical science were in the way of prevention by better sanitation. Just now there is a great raid being made on flies. I can remember when we could not eat our dinner in peace without slapping flies right and left; and one glorious part of it is, the children are helping. A good many times they are doing the work. I spoke about the wonderful things the *boys and girls* are doing in the way of raising more and better corn; and I said the same thing might be done with potatoes. Well, it is already done, as I see by the agricultural papers.

Now, all intelligent family physicians are telling us everywhere, not only in the cities but in the country towns and villages, how to prevent disease. They are teaching us modern sanitation. I am ashamed to say that, until about two years ago, I thought bathing every Saturday night was sufficient. Now you could scarcely hire me to go back to that way of living. Every inch of my body has a good wetting, and a good rubbing with a dry towel, every day of my life, either in the morning or before I retire, as is most convenient. Well, it is not only the better health I enjoy, but very much cleaner clothing. The wash-woman's task is lessened (down in Florida the dear wife

does all the washing); my light underclothing at the end of the week is often so clean that, if I get it mixed with the new, I can not tell one from the other. The sheets on our bed are never soiled, even if I have been perspiring freely during the day, for in that case I take my bath before retiring. No matter what your occupation is, nor who you are nor how old you are, if you want to be up with the times keep yourself clean by a daily bath. You do not need a bath-tub. If the room is too cold, strip off to the waist, and when you are thoroughly washed so far, put something over your head and shoulders while you finish the rest of your body. With a little practice you can wash yourself thoroughly all over without making any slop where you stand. I forgot to mention in the proper place my nightgown. This, too, is so clean because I am well washed before it is used, that when Saturday night comes I hardly know it has been used. Now, so much for the body. If you are keeping up with the trend of thought, invention, and discovery, you are sleeping outdoors, or with so many doors and windows open (screened, of course), that you are practically out of doors. While I am about it, let me say, help the good wife to keep your living-room as clean as your body by being very careful to clean your feet whenever you come in to dinner or for any other reason. Wear some sort of overshoes when obliged to go out on ground that might stick to your feet. And, finally, be careful about the cellar. The Cyphers people, in their directions for making and using an incubator cellar, say that the walls and floor should be scrubbed thoroughly every few days, or mold will accumulate that will mean death to the chicks inside of the egg. The cellar should be damp, and this dampness is congenial to the

growth of mold and of injurious bacteria. Have it so made that you can let in some sunlight a part of the day, and then give it a frequent sweeping or scrubbing two or three times during a hatch. Now, if this is good for the chickens, it is also good for humanity; and the Master said, you know, "Ye are of more value than many sparrows." For the sake of the dear ones who live in the rooms above, and for the sake of preventing epidemic and contagious diseases that might harm your neighborhood, keep your cellar as pure and wholesome as you do your body and your dining-room. I am sure the good wife will warmly second your efforts.

If apples or potatoes or other vegetables are rotting in your cellar, overhaul them and remove the decayed ones certainly once a week. I sort over my eating apples every 48 hours; and late in the spring, when the old apples begin to rot badly, I sort them over every day, using every apple just as soon as it shows the *first symptom* of decay. In that way I always have nice ripe mellow apples, and there is almost no loss; and when apples are from 50 cts. to \$1.00 a peck it does not pay to let them spoil.

Now let your wife read this little health talk; and may be it would be a good idea to show it to your neighbors. Tell them I am starting out to be a hundred years old; and I should like to have every (good) man and woman who lives, and all fellowmen, join in with the Century Band. At present our good friend T. B. Terry will make a very good leader.

HYDROPHOBIA, ETC.

Mr. A. I. Root:—I have just read your article, p. 771, Dec. 15, on hydrophobia. I want to thank you, and congratulate you for giving space and publishing that timely article. I only hope that every beekeeper and farmer, as well as dog-fancier, could read your words on a subject that demands our attention. I am going to do all I can here to get the taxes raised on dogs, and a law to compel dog-owners to muzzle their dogs. The loss of human life and valuable domestic farm animals can never be balanced with a pack of worthless dogs.

Just a few days ago I lost an animal in the way of a fine mule—one that \$250 could not buy. The mule, a faithful trusty servant of our household, was bitten in the nostrils by a stray worthless cur that was not worth the powder and lead that were shot at him. Just 34 days from the time the mule was bitten it died in convulsions. Its sufferings were something terrible; and, to make it all the more so, we could do nothing to relieve its suffering, as one convulsion followed another in rapid succession until death relieved it. It suffered somewhere near three hours before death came.

Mr. Root, as soon as I read your article in GLEANINGS I simply had to write you this letter.

SAMUEL M. ANGEL.

Evansville, Ind., Dec. 26.

THE OTTAWA "LUCKY STONE," ETC.

I had fondly hoped that the days were past when people would put their faith in something carried in the pocket to bring "good luck." But just now I am pained to get a lot of printed matter with the heading above. These lucky stones are for sale, of course; and there is a lot of "testimonials" to prove that, if you have this thing in your pocket, all your investments and speculations will turn out profitably. I suppose

that, if you should buy a lottery ticket, it would draw a prize every time, if you are a possessor of that lucky stone. Now, it is a disgrace to the present age, and a slur on the postal department, to permit such things to be carried in the mails, and I am going to carry the matter to the Postoffice Department authorities. In running over some of the testimonials I was wondering what it was that sounded so strangely familiar; and then I recalled that the testimonials in regard to Electropoise and Oxydonor were almost parallel. I wonder if the postal department will also decide that it is not their province to interfere with using the mails for traffic in these lucky stones. The vendors even have the cheek to drag in the names of Lincoln, Grant, Edison, Carnegie, etc.

Just now the price is only the insignificant sum of \$1.00; but owing to the "immense demand" they say the price will soon be boosted up to \$10.00 each.

BIG POTATOES, ETC.

Mr. Root:—I want to ask you if the A B C of Potato Culture says that all potatoes will be big enough if they go only 40 to the bushel for the biggest ones. If so, we got you beat a mile. We grow potatoes as big as 3 lbs., and don't think much about it, although that would make only 20 potatoes to the bushel.

Comfrey, Minn., May 15. C. G. GABRIELSON.

My good friend, the potato book does not make mention of potatoes larger than 40 to a heaping bushel. No doubt we *can* grow them larger if we undertake to do it. But let me tell you of something that happened. My neighbor, James Hilbert, in Northern Michigan, grew, I think, about 1000 bushels that he *could not sell* because they were so large that nobody wanted them. They were Carman No. 3. I told him, when he planted them the usual distance on his extra-good ground, that he would have trouble by having too many of his potatoes too large for market; and I suggested that he should plant them close, and use large pieces for seed so as to make the potatoes small. I think their usual rule up there is 3 ft. apart both ways. The potato book recommends, as you will notice, very much closer planting than this, in order to avoid getting potatoes that weigh 3 lbs. I suppose this present spring of 1912 big potatoes or little potatoes or any other kind will sell without any trouble, and bring a big price at that.

FROM AN 85-YEAR-OLD FRIEND

You did send me one of your catalogs, but I am no more able to tend to bees. I am going on 85 years, but I appreciate very much your sending me that. All I want to know is if, A. I. Root is alive yet. He was one of my best friends. I did deal for many dollars' worth of goods with him. He was an honest man. I am a veteran of the civil war. I was raised in Ohio, in Stark county. I am a Frenchman. Please take a little pains and let me know about Mr. A. I. Root.

Parkville, Mo.

ED LANFELIN.

[My good friend, we are glad to tell you that A. I. R. is just now very much alive, and, through God's providence, he hopes to live to be as old as you are. We send you some of our back numbers in order to let you know how your old friend is busying himself during this year of 1912.]

NO. 12

Editorial

DEATH OF DR. JOHN S. HOWKINS.

DR. JOHN S. HOWKINS, one of the prominent beekeepers of Savannah, Georgia, and for a number of years connected with the beekeepers' supply business under the firm name of Howkins & Rush, at Savannah, died recently. Mr. Howkins was a man who stood high in his profession, was a man of personal magnetism, and had hundreds of friends in Savannah who loved him for his warm, true-hearted nature.

THE BULLETIN ON SWEET CLOVER.

WE are informed that Bulletin 98, Bureau of Entomology, entitled Historical Notes on the Causes of Bee Diseases, and Bulletin 485, from the Department of Agriculture, on the subject of sweet clover, are not for free distribution. Five cents is the price of the former, and ten for the latter. But they are well worth the price—especially the bulletin on sweet clover, which every beekeeper should secure before the supply is exhausted.

100 LBS. OF SECTION HONEY BEFORE MAY 28.

THE following letter received from one of our subscribers will explain:

On May 2, 1912, I had two swarms that clustered together. On May 28 this colony gave me 100 lbs. of fancy section honey. Is that not a good yield for Virginia?

Petersburg, Va.

W. E. FERRELL.

While this, perhaps, is not "breaking the record" by any means, it goes to show that the conditions are going to be right for a honey-flow this year. Reports are looking good for a good old-fashioned flow, where there are bees to gather it.

GLEANINGS UP TO DATE.

PERHAPS our discriminating readers will observe that this issue is printed on a new face of type. More exactly, every issue of this journal from now on will be printed on an entirely new face. Our new \$4000 linotype, which we purchased last December, has been kept busy at work on various pub-

lications sent out by the GLEANINGS publishing house; and it was not until this issue that we were able to catch up enough so that our journal could be set on the machine. Machine composition will, therefore, be used hereafter in our printing rooms. One person is now able to do practically as much work as four or five compositors.

GLEANINGS is being set up and printed on the most up-to-date machinery that it is possible to produce. We are using the most modern appliances for making our photos and engravings, including the very latest new patented "overlay" by which the halftone cuts come out brilliant and clear.

IS THE SPRAYING OF FRUIT TREES WHILE IN BLOOM NECESSARILY INJURIOUS TO EITHER BEES OR BROOD?

SOME question has been raised in this country whether the spraying of fruit-trees while they are in bloom is damaging to the beekeeper, as has been commonly believed. We have always supposed (basing our opinions on reports from all over the country) that such spraying was injurious, particularly because thousands of dead bees have been reported at the entrances of hives in localities at just the time the trees are sprayed when in bloom, and because brood is found dead at about this time. But there are some authorities, however, who believe that the dead brood in most if not all of these cases is due to foul brood rather than to poison. But foul brood does not account for dead bees in front of the entrances; and particularly does it not account for a rapid decimation of the strength of the colony while the trees are in bloom.

We are always willing, however, to give the other side of any question; and from the *Agricultural Gazette*, of New South Wales, for April 2, we learn that Messrs. E. E. Prescott, Principal of the Horticultural School at Burnley, and F. R. Beuhne, a

beekeeper well known to our readers, conducted some experiments to ascertain whether the spraying of fruit trees with poisonous mixtures while in bloom had any effect on either the bees or the brood. The result of their experiments is summarized as follows:

At the Burnley apiary, the beehives are right under the fruit-trees, and at the time of spraying with Bordeaux mixture the ground had not yet been plowed, so that the spray fell not only on any fruit blossoms that were open, but also on the Cape weed then abundantly in bloom.

Neither the spraying with Bordeaux mixture nor the subsequent one with arsenate of lead had any effect whatever upon the bees, the colonies developing normally, and without any checks. There was not at any time dead brood in the hives. There is no doubt that under the atmospheric conditions prevailing at the time the spraying of the trees proved quite harmless to the bees. Observations will, however, be continued in future, to demonstrate whether spraying is injurious to bees at all; or if so, under what conditions.

ROBBER CAGES.

On page 383 of our Heads of Grain department in this issue is an illustration of a portable robber cage mounted on wheels to set over a hive. Practically the same thing without the wheels, and much smaller, or just large enough, to set over an ordinary hive, we find a very serviceable thing to have in the apiary. The advantage of the smaller size is less weight with corresponding greater portability. In the cage shown on p. 383 the operator can be caged with the hive of bees.

We use also a robber cage (large enough for operator and hive) that is very light. It has a cross rail or handles on each side, and a convenient screen door. One can step inside, lift the cage up by its cross-rails, walk over to the hive that needs attention, and set it down.

In our judgment, wheels only add to the weight and to the inconvenience of getting such a cage from one part of the apiary to the other. Our large cages for setting over the hives are made of strips of basswood $\frac{7}{8}$ inch square, and do not weigh over 5 lbs.

WILL IT BE AN OLD-FASHIONED HONEY YEAR?

INDICATIONS in our locality (and we hope it is a fair criterion of what it will be in other clover districts of the North) point to an old-fashioned honey year. While there is, perhaps, not as much white clover out as we have some years, yet what we do have seems to be yielding nectar. Both red and alsike clover are very abundant in our locality, and the growth is luxuriant. Apparently the severe winter did not hurt either very much if at all; and that reminds us that years ago, when we used to have a yield of clover honey every year, we had cold winters. Is it possible that a cold

snappy winter like we have just had causes nectar to be secreted more readily the following summer? In the language of Dr. Miller, we don't know.

Another thing that is encouraging is that basswoods look more promising than they have before in a decade. While the indications are for a good honey-flow, we fear that not every one else will be as well favored with bees as ourselves.

In the mean time there are some reports from California that look rather encouraging. How reliable our information may be we do not know; but several clippings have been sent us that would indicate that there will be 500 carloads of honey in California. We do know this — that many carloads of bees are being sent from the bordering States into California to catch the flow after which they will be sent back to their respective States.

Our representative in Texas wrote us a short time ago, saying that he thought the crop in his State was going to be light. While the early indications were good, the flow did not materialize. We hope it will not turn out this way in our northern States.

THE CAUSE OF EUROPEAN FOUL BROOD.

It will be remembered that Dr. G. F. White, of the Bureau of Entomology, Expert in Bacteriology, and working under the direction of Dr. E. F. Phillips, Apicultural Expert, has been investigating the causes of bee diseases for several years back. After devoting something like a year or more to the special study of American foul brood he definitely located the bacillus responsible for that disease; namely, *Bacillus larvae*. He proved beyond any question that *Bacillus alvei*, supposed to be the cause in former days, had nothing to do with it. But he did find *Bacillus alvei* in samples of European foul brood. It seems that he has been working upon this type of the disease for the last two years; and while he will not as yet make any positive statement it would seem to us that he has come pretty near locating it. He finds among other microbes in the dead brood from the European foul brood, *Bacillus alvei* and *Streptococcus apis*. He also found the old *Bacillus Y*, which he discovered some time ago, and which he at the time suspected might be the cause of European foul brood; but before he could get more evidence he came to no conclusion.

Circular No. 157, by Dr. White, just out, gives some interesting information. Among other bacilli he finds *Bacillus Y*, or *Bacillus pluton*, as he now designates it, and under

conditions that would seem to show to the average layman at least that this bacillus is responsible for the real European foul brood. He has proved beyond any question that the other bacilli mentioned, when fed from pure cultures to healthy brood, do not cause any disease, although they may or may not be present. The *Bacillus plution*, however, is discovered at the very beginning or the first symptoms of the disease, and continues clear on through. Later on, as the disease develops, *Bacillus alvei* and *Streptococcus apis* develop. Whether they have a tendency to modify the form of the disease is not quite clear; but from all the evidence presented it would look as if Dr. White had found the real cause of European foul brood, although he does not definitely claim it even yet. It has taken a long time to do it; but it has been worth while.

Copies of this bulletin can be obtained by applying to the Superintendent of Documents, Government Printing Office, Washington, D. C., enclosing five cents. Stamps will not be accepted.

THE CHEMICAL ANALYSIS AND COMPOSITION OF IMPORTED HONEY FROM CUBA, MEXICO, AND HAITI.

THE foregoing is the title of Bulletin 154, from the Bureau of Chemistry, by A. Hugh Bryan, Chief of the Sugar Laboratory. It is well known that honeys vary slightly, owing to different climatic conditions in localities from which they are gathered. As various honeys are being imported into the United States, it is important to know their exact chemical composition, for comparison with certain other honeys that might be imported, or which are alleged to be imported, but really are an adulterated honey pretending to be what it is not. The results of the examination of honeys from Cuba, Mexico, and Haiti show a "slightly greater moisture content and a somewhat lower percentage of sucrose." Otherwise there is no pronounced difference.

Further particulars can be secured by applying for a copy of this bulletin to the Superintendent of Documents, Washington. It is not stated whether there is any charge for this, but probably it is about five cents. Do not send stamps, as the governmental departments can not use them.

THAT SECOND CARLOAD OF BEES FROM FLORIDA.

THE second car arrived at Medina, with our man in charge, June 1, in record-breaking time, being only five days from the time

of starting from Patrick's Landing, Florida, till it reached Medina, covering a distance of 100 miles by water and 1000 by rail. As in the former case, Mr. Marchant stayed with the bees in a cattle-car night and day, for the bees required almost constant attention. It was necessary to give them water, and keep them sheltered from the direct rays of the sun when at stops. The previous shipment of bees took eight days: this one just in, five days. This difference is due, first, to a shorter route; and, second, to a better knowledge of how to handle railroad men.

The second lot of bees did not come to us in quite as good order as the first, however. The first carload was made up of 500 three-frame nuclei. The second car contained 248 ten-frame colonies, screened top and bottom. In some cases there was a quart or more of dead bees on the bottom of the screens, but in most cases practically none.

Both shipments proved beyond a question the importance of having a man along with the bees, and not only in the same train but in the same car. When weather conditions are fair, a man can travel with a fair degree of comfort. The first carload of bees started when the weather was extremely hot, and landed here in a snowstorm with a temperature nearly down to freezing. The second shipment had extremely hot weather all the way; and this, we think, accounts in part for the larger loss of bees; for on the previous shipment there were almost no dead bees.

Another lesson we have learned is the importance of shipping bees (for so great a distance) in *smaller* packages. A full-sized ten-frame colony will not stand a long shipment as well as a fair-sized three-frame nucleus. It sometimes happens that one lot of bees are more nervous than another. The larger the unit of shipment, the larger will be the relative loss, for the reason that a small lot of bees can not stir up a whole colony. It was noticed that, with both nuclei and full colonies, some of either would be roaring as if in a terrible state of excitement. Wetting them down would aggravate the roar for a moment, when they would quiet down. Excited bees always require more air; and it is such bees, like nervous horses, that wear themselves out long before they get to the end of their journey; hence the importance of a man with a sprinkling can.

This carload of bees is now being distributed around at outyards. From present indications they will gather enough honey to pay the freight; and possibly, if we should have a good shower of honey, their entire cost.

Stray Straws

DR. C. C. MILLER, Marengo Ill.

FRANK E. MILLEN, if you feed sugar to fill the brood-chamber, as suggested on p. 316, please have the first super honey analyzed to see if sugar is in it.

NEARLY 4000 virgins were sent to the 36 mating stations in Switzerland last year, and 87 per cent of them were returned mated.—*Schweiz. Bztg.*, 484. [Some of this might be practiced to good advantage in this country.—ED.]

D. M. MACDONALD, *British B. J.*, p. 103, says spreading brood "is a pitfall — a plunge into which is accompanied with ruinous consequences when practiced by the novice . . . ; even the old hand, for his own good, should be advised to resort to it but seldom." I have some question whether there is *ever* any gain by it.

BERNARD RIETSCHKE, who died lately, had already (in 1896) sent out into Germany and other lands 10,000 comb-foundation presses, and since then the number doubtless has more than doubled. Your thrifty German doesn't like to buy what he can make himself. More than that, German beekeepers are not blest as we are in being able always to buy foundation with the secure feeling that there is no such thing as adulterated foundation upon the market.

ALL LIFE, says John H. Lovell, p. 268, depends upon the existence of leaf-green, or chlorophyll. If I had known that some years ago it would have saved me some trouble. Madame Salleron is a geranium with ornamental foliage, some leaves green, some white. I wanted a plant all white; tried to root branches with all white leaves. All died without rooting. Then I thought I'd make a sure thing by taking rooted plants and cutting out all green leaves. Every plant died. Couldn't live without the green.

I'M GLAD, J. L. Byer, to see you object to using "hybrid" in place of "cross-bred," p. 264. I wasn't on the carpet when it came into use, so had no chance to protest. But I'll stop using it if you will. But you're 'way off in thinking I'll ever be reconciled to "shook swarming." That's such a vicious violation of grammar that it will always cause a shudder except among those people so illiterate as to say "I was took down with fevernager and was nearly shook to pieces." [While the use of the word "hybrid" is not scientifically accurate, because it is not a crossing of species but a crossing of *races*,

it has become established in all our literature. It would be almost impossible to change it now. We say, in common language, the sun rises, when we know that it does not rise. As a matter of fact, we are doing the rising, because our part of the globe is coming to a point in its revolution where all can see the sun. No, we believe it is better for us to continue using the old term—particularly so as it is shorter than "cross-bred," which is more accurate.

GLEANINGS has always held, I think, that if sugar is fed in the brood-chamber there is danger it might later go into supers; but I don't know that there was ever any positive proof. A careful experiment is reported in *Schweiz. Bztg.*, 149, April 6; to one colony invert sugar was fed; to another, cane sugar, each containing a minute quantity of lithium chloride. April 19 the flow began, and the honey-apartments were opened. May 4 samples of surplus from each showed the presence of lithium, and no lithium in the surplus of a neighboring colony. Clearly it is wrong to feed sugar shortly before giving supers. [We have based our opinion and advice in this matter on the testimony of a number of practical beekeepers. One of the most conclusive, as we now remember it, was the case of a correspondent who fed very dark buckwheat honey just before the clover flow. What was his surprise to find that the sections over the colonies fed with buckwheat contained a good deal of dark honey; while colonies not so fed had white section honey. There was so much testimony along these lines, that we believe late sugar feeding should be discouraged. While sugar syrup in section honey would not affect the quality of the best section honey, yet when such goods are put on the market they are likely to subject the seller or producer to the penalties for selling adulterated goods. It is true a very small proportion of sugar syrup might not be detected by the chemist, but a larger amount would. Moreover, we do not believe there is any advantage in late feeding except to prevent actual starvation and the cheeking of brood-rearing. There is no harm in late feeding in any case providing the bees are not fed too much. This whole question was thrashed out when the Boardman plan of feeding sugar syrup clear up to the harvest was advocated some years ago. There are some seasons when the *expert* can practice such feeding without getting sugar syrup into sections.—ED.]

SIFTINGS

J. F. CRANE, Middlebury, Vt.

It seems as though I never knew a spring when bees spread their brood so fast, considering the weather.

The March 15th issue of GLEANINGS ought to be placed in the hands of every fruit-grower in the United States.

Friend Scholl keeps hammering away at "bulk honey." The argument advanced that more can be sold near home in this way is quite true, and of immense value when there is a large crop to be worked off.

Mr. Doolittle's ideas as to what constitutes a well-to-do man are perhaps of more value than any thing else in the number of GLEANINGS for Feb. 15. They will do to carry with us for meditation in our leisure hours.

It is bad enough for a busy man to get letters asking for information without even enclosing a stamp to pay for the postage; but when one gets a letter asking for the whole science of beekeeping, on a postal card, it caps the climax.

Mr. Chadwick, page 155, March 15, gives us some interesting reading, much of it as applicable to this side of the continent as the other. The fact that one man who put up bulk comb honey for only one season created a permanent demand for it is very significant.

I was very much interested in reading Mr. E. H. Shattuck's article on the tobacco industry in the Connecticut Valley, p. 162, March 15. I visited some of those fields under canvas last year, and found the bees working on the flowers. It is a pleasure to know that something as good as honey can come from this plant.

"Never too old to learn" is as true as old; and that photo of baby Curt Lundgren, that has been fed on milk and honey from its earliest infancy, teaches us one thing more about honey—that it is good for babies. We might have surmised as much; but we are so stupid as not to think. The land that in ancient times flowed with milk and honey has produced some of the noblest men the world has known, and one of the most virile of all nations—one that no amount of persecution or injustice has been

able to destroy—whose moral ideals have helped to lift humanity higher than any other. Hurrah for "milk and honey!"

How often we come across something that seems to upset all our fine-spun theories! I found a hive this morning with an entrance large enough to suit our friend Latham or Arthur C. Miller, and it was among my best ones too. Seven large combs of brood before a single apple-blossom appeared.

Travel where one may, through the length and breadth of the land, the banishment of the saloon seems to be a live question everywhere, and of more moral and economic importance than any other now before the American people. Some day this generation will surely be the object of ridicule for the silly and stupid methods of regulation now in vogue.

The early spring shows that bees have wintered very badly in Vermont. Where they were able to get a fair amount of honey last year, or where they gathered some the latter part of summer, they have wintered fairly well; but all colonies that were short of honey during most of the season have come through in bad shape, which to me shows very conclusively that the wintering problem depends a good deal on the previous season.

A good deal is being said about the folly of carrying all one's eggs in one basket. This is especially true of the South. One man raises all pineapples, another oranges, another celery, another tomatoes, another lettuce, and another bees; but it is risky. One man near where I boarded for a time said he made more money playing poker the week after he joined the church than in all his life before. Some one chided him for his unseemly conduct; but he said he could not see that it was any worse to bet on cards than on a crop of vegetables. If the season is favorable, and markets good, you win; if not, you lose. And do we not often tempt Providence when we attempt to carry all our eggs in one basket? If the poultry business can be made to fit into beekeeping as neatly and successfully as it is illustrated in GLEANINGS for Feb. 15, we beekeepers need not carry all of the eggs in one basket, but have two baskets and enough to fill both.

Beekeeping in the Southwest

LOUIS SCHOLL, New Braunfels, Texas.

THE CONFUSION IN REGARD TO PROPORTION OF COMB AND EXTRACTED HONEY IN A PACKAGE OF BULK COMB HONEY.

There exists a great difference of opinion among beekeepers, even in Texas, the home of bulk comb honey, as to the exact way this product should be put up for the market. Although the packages used almost universally are standard, and especially adapted to the purpose, the mode of filling these varies with different beekeepers. The result is that occasional complaints are made by honey-buyers, caused by receiving packages which have not been uniformly packed, due to the fact that the purchases have been made from more than one producer. A first purchase may consist of packages containing more comb honey in proportion to extracted than is ordinarily put in. The next purchase may be made up of less comb honey and more extracted. The producers in each case have, perhaps, tried to be honest, and have been willing to furnish the best that could be supplied. The first tried to give "full value" in putting in as much comb honey as possible; but by so doing found it impossible to make up the required weight of the package. Comb honey being lighter in weight than extracted, it naturally follows that the more of it that is placed in a package the less the weight will be. So while giving full value by putting in more comb honey there must be loss in weight of the entire package.

The other beekeeper, then, tries to give full value by giving full weight. To do this it is necessary to make the quantity of comb honey smaller and the extracted honey larger until the proper weight is obtained. Just what the proportion should be is the question that should be decided upon by producers and purchasers alike, so that a standardized method of packing may be adopted.

No grading rules exist governing bulk comb honey, and it is doubtful whether such are necessary under present conditions. A general rule, understood by all honest producers and buyers, is that the honey must be of good quality and flavor. This means that both the comb and extracted honey, which constitute the product known as bulk comb honey, must give satisfaction so far as quality and flavor are concerned. Rather less attention, perhaps, is given to the color of the honey.

While it is generally understood by many producers as well as honey-buyers that the

gross weight including the package is figured in the price of the honey, there are many who do not know this. This causes much confusion. If prices are quoted on two 60-pound cans to a case, that would mean 120 pounds at so much per pound. Since the regular or standard 60-pound cans do not hold this in net weight, some buyers complain because of the shortage of the contents. This is especially so with retailers who sell honey in small quantities and find that a 60-pound can, for which a certain price a pound has been paid, falls from 1½ to 2 pounds short in weight. It is a matter that should receive immediate attention, and should be adjusted so as to meet the demands of all concerned, as far as possible, before the active shipping season begins.

In this connection the pure-food laws should be considered. It may be well to think over the question of the tags used on the shipping cases. For example, a doubt may arise over the meaning of a tag marked "One case two 60-pound honey," whether it be extracted or bulk comb. The point in question would be whether the label ought to indicate 120 pounds net or gross weight, especially since the case of honey is figured at 120 lbs. at so much per pound. It is very rarely that honey-packages are labeled by the Texas producers; but the cases containing them for shipment usually bear the above-mentioned wording on the shipping-tag. Besides this the price lists quote the various sizes in regular order, "Two 60-pound cans to a case at — cents per pound;" "ten 12-pound friction-top pails at — cents per pound, etc.," which may give the impression that this is intended for the net weight of honey, while it ought to cover the gross weight, because the regular standard cans do not hold the full weight.

We want to hear at once from all who are interested in this matter, as to what steps should be taken toward standardizing the packing of bulk-comb-honey packages, as well as extracted honey, and the proper labeling of the same, to prevent confusion and the possibility of violating the pure-food laws.

Your opinions are greatly desired, and will be appreciated; so, let me hear from you immediately. A few lines on a postal will suffice if there is no time for a letter; but a more lengthy discussion by letter would be preferable.

Conversations with Doolittle

At Borodino, New York.

SECURING WORKER COMB WITHOUT USING FULL SHEETS OF FOUNDATION.

"I wish to know how to have my bees build worker comb without foundation."

"Why do you wish to get along without foundation? Most beekeepers use it in the frames, and get the nicest worker combs."

"Well, I had to spend all the bees brought in, and some besides, to buy sugar to feed for winter stores, and I do not want to run in debt if I can make the increase I wish from combs built by the bees. Then I read the other day in an old bee paper that when bees are storing honey a certain amount of comb may be built at practically no expense, as the bees then secrete wax that would otherwise go to waste."

"Well, there is a grain of truth in such a statement; and if you have no money to invest in comb foundation it may be a wise thing for you to try having the bees build their own comb. But at this season of the year they are likely to build drone comb."

"That is the reason I came over to see you. I want you to tell me just what conditions are favorable for building worker comb, and how I may manage my colonies in such a way as to avoid drone comb."

"I used to let my bees build most of their combs, and at first inserted a frame having a starter of worker comb between two full ones; but finding that the bees would almost invariably build only drone comb, this was given up with the average or stronger colonies of bees."

"Is it true that weak colonies always build worker comb?"

"In a certain sense, yes. But colonies which are considered weak in May often become so far advanced that, when this time of the year comes, they are as determined to swarm as any, even though they may not have more than half the number of bees that a good swarm should. Such colonies will build only drone comb if the frames are spread apart and a frame having only a starter in it is inserted. But take such a colony as this, and deprive it of all its combs save one of honey and one of brood, then insert a frame having a starter in it between these two combs left in the hive, the bees will, forty-nine times out of fifty, fill that frame with worker comb, and then it will resemble any comb built from foundation under the most favorable circumstances. When I want the bees of such colonies to build worker combs I take frames of brood from the weaker colonies

I may have at the beginning of the nectar-flow—those too weak to work in sections to advantage—and give this brood to the weaker of the colonies I have set apart for section honey, and then set the weak colonies thus treated to building comb as I have explained. In this way I really make a gain in section honey, as this brood brings the colonies having it to the point where they can take advantage of the harvest; while if it had not been given such colonies would hardly have entered the sections before the flow of nectar was on the wane. If the brood had remained where it was, that colony would not have become strong enough for the sections until the time of the buckwheat yield, and thus little white honey would have been secured from either colony. But with the three or four frames of brood given to the one that would have done very little in the sections, the results will equal those of any of the colonies which were stronger in the spring."

"Is there any way of making the new swarms build worker combs?"

"Yes, if such swarms have a good prolific queen. If you have a ten-frame Langstroth hive, hive the new swarm on the whole ten frames, each having a starter of worker foundation in it. At the time of hiving, put on a super of sections, each row in the super having a bait section, using a queen-excluder between the hive and super. These baits allow the bees to store their first-gather honey, and that which was taken from the old hive, so that comb-building in the frames is only for brood. Two or three days after hiving the swarm, take out five of the frames having the least comb in them, closing up with dummies the space left vacant. The bulk of the bees are thus thrown into the sections, into which goes all the honey not required by the bees and brood, thus keeping storing going on to the fullest capacity, while the queen keeps up with her eggs as fast as combs are built below. In this way five worker combs will be built to perfection, and a good yield will be secured from each swarm."

"You do not try to winter the swarm on five combs, do you?"

"No. When the clover flow begins to draw toward a close, five combs, built by the manipulated weak colonies, are given to the swarm, and in this way the hive is filled out for winter, with *all* worker comb, while the bees always have an abundance of stores unless the season is unusually poor."

SHIFTING THE HALVES OF A DOUBLE BROOD-CHAMBER TO PREVENT SWARMING

Forcing all the Honey into the Supers by Interchanging the "Laying" and "Hatching" Brood-nests; Separating the Queen from all Brood Every Ten Days Without Making her Stop Laying or Causing the Loss of any Brood

BY J. H. YEOMANS

For a few years I have been experimenting to perfect a "system" of handling bees for the production of comb honey when the beekeeper can not be at home during the day. I have received many ideas from other beekeepers, and have read many others; but usually there are some details that I do not like; hence I should like to submit the following, subject to the suggestions and criticisms of my fellow beekeepers.

My first aim was to have a "hatching story." In the spring, when the hive showed signs of becoming crowded, I added a second story. This delays swarming if added early enough. Then as soon as a honey-flow promised some surplus I raised this top story, putting supers between the two stories with a solid wire screen on top of the supers and below the hatching story. Then I found the frame with the queen and put her into the lower story, shaking the bees from about half of the frames with her. Then in about three days I shook half of the frames again, and in three days I repeated the operation. On the tenth day I cut all queen-cells that I found, and put the "hatching story" on the bottom and the brood-nest on top, and repeated the process.

While performing these operations I noticed that all dead bees were being put in the *lowest depression* of the wire screen. This made me think the bees were trying to carry out the dead ones, and so I hit on the idea of putting a bee escape at the lowest point. This works well except that for the first few days it is apt to be clogged with dead bees. After a few days, when old bees are gone from the hatching story, there is little trouble. I would advocate building a screen with several bee escapes.

My theory is to provide the queen with ample laying room, and to hatch all the eggs she lays up to a certain date, which should be decided by each beekeeper. I think that, where the fall flow is not profitable, it does not pay to raise a lot of bees to feed during a period of no surplus. With me most of my surplus comes in June and July; so I plan to stop my "switching of

stories" about June 1. Then I leave the queen in the lower story and let the upper story hatch out *entirely*. Then I put the upper story away until fall. When I take off all supers my colonies are so strong that for the past two years I have had to winter them in two-story hives.

I have no difficulty in making 100 pounds per colony with Danzenbaker hives. On one colony last season I had 128 sections at one time between the "hatching story" and brood-nest. No matter how cold the nights (our nights in Washington are nearly always cool), the bees will start work immediately in the sections between stories. Each year my system has been improved, I think, in some particulars. By making the bee-escape partition of wire screen, it allows the heat of the brood-nest and supers free access to the "hatching story." I have examined closely on the ninth day, and have found the bees capping larvæ, the eggs of which must have been laid the day I made the switch. Furthermore, I have left the hatching story on in June until every cell had hatched out, proving that no eggs or larvæ are destroyed, and that all sealed brood will hatch.

THE IMPROVED PLAN USED NOW.

My present practice is as follows:

1. In early spring I put on a second brood-chamber.
2. As soon as the queen has laid some eggs in both stories, and it is time to put on supers, I raise the upper story and put supers between them with the escape screen on top of the supers and below the hatching story.
3. I make sure the queen is in the lower brood-nest, or *laying brood-nest*. The top brood-nest is the *hatching brood-nest*. I keep the queen in the laying brood-nest all the time, except that I have found it saves time to wait 24 hours after making each ten-day switch before hunting her in the top story. This gives the field bees time to go down through the escape screen, and they are out of the way, making it easier to find the queen.
4. Ten days later I switch the laying brood-nest to the top of the colony, above the escape screen, and, after cutting out queen-cells, I put the hatching story at the bottom of the colony and make it the laying story for the next ten days.
5. I repeat this every ten days as long as I desire to increase the colony strength. I begin switching about May, and continue the practice every ten days until perhaps June 10. I introduce a young queen to

the hatching story; kill the old queen, and force the bees into the supers for the rest of the season. (A laying queen may be kept in each brood story, but one will have to switch stories as usual or the top story will run out of its supply of honey and pollen.) This system separates the queen from all brood every ten days, without stopping her laying, and without the loss of any brood.

I watch the bee escape to keep it clear for passage of the bees that wish to get out. They go to the fields for honey, come back, and find their *storage* in the usual place relative to the hive entrance. The field bees and those of age of first flight are the first to go below, and they increase the field force just as wanted. The nurse bees are left with the eggs and larvæ, just where they are wanted. They use the honey and pollen stored in the hatching story, which cleans up and makes room for the queen to lay at the next switch. This system separates the queen from all brood every ten days without stopping her from laying, or causing the loss of any brood.

I put on an old comb, badly clogged with pollen, in the hatching story (for an experiment) with the rest of the combs, mostly new, and with little pollen in them. The bees cleaned the comb in fine shape, and raised all the brood.

On the tenth day, when I cut out all queen-cells in the hatching story, and put it below, ample room is provided for the queen to lay, and more added daily by those hatching. In fact, the daily hatching in the brood-nest for the ten-day period the queen occupies it will keep her busy a good part of her time. I have no trouble whatever from the bees clogging the brood-nest with honey. So far I have had to feed every fall, as all the honey, or nearly all, goes into supers.

INTRODUCING QUEENS.

This system is the finest one I know of to introduce queens. Twenty-four or thirty-six hours after you switch stories, introduce your new queen to the top story. As this is occupied only by young bees, they will readily accept her. I have never lost one. If young queens can be obtained early enough, one can be introduced above, and both queens allowed to lay for a week or two, and then the old one destroyed—that is, I let both lay up to the date that the bees will hatch, so as to be of use during the honey-flow. I never use both queens until there are so many bees that they will eat all of the surplus. I did that one year on a colony that promised me 250 pounds. They were so strong all summer that it took two full-sized brood-nests to hold them in

the fall, and my crop was only about 125 pounds. This was a colony from which I had planned to extract in the fall, and had it seven stories high, with bees working in every story.

Swarming has been eliminated in my apiary entirely. A few minutes per colony once or twice a week, at morning or evening, will be sufficient to handle this plan quite satisfactorily. The screen between supers and top story should allow bees to go down and not up. Several bee escapes should be arranged so as to make egress easy.

Spokane, Wash.

AN OUTSIDER IN COLORADO

BY DR. E. F. PHILLIPS

GLEANINGS maintains a department conducted by the Colorado State Inspector of Apiaries; but it may be of interest to mention a few points which came to notice during a recent hurried trip which I had the pleasure of taking through the State. Mr. Foster, who also went with me on this trip, naturally sends items which will appeal more especially to the Colorado beekeepers; but those outside may desire to get some idea of conditions in the State which he might not think of giving. There are some things which may be mentioned which have such an obvious moral that the reader will possibly conclude that these descriptions are being given solely to air personal views. This is not always the case; but the adverse criticism (if it is such) will be accepted gracefully. Another advantage in discussing Colorado beekeeping after a brief visit is that it gives Colorado beekeepers, and especially Mr. Foster, such a glorious opportunity to correct errors which are almost sure to appear. If any such are detected, no person wants to know it more than I; for naturally some conclusions were necessarily drawn from small accumulations of data.

DISEASES.

Since my trip was particularly for the purpose of studying the brood-disease situation it may be as well to say something of that first. American foul brood has been prevalent in Colorado for many years, and is now present in nearly every beekeeping location in the State. In Boulder County, for example, where the beekeepers have had years of experience with the disease they have lost their fear of it, and never allow it to cause much loss. On the western slope, however, where it is seemingly of more recent introduction, the beekeepers are not yet so well informed, or perhaps less con-

fidant on this subject, and, as a natural result, the disease is causing greater loss. This is an exact duplicate of the experience of beekeepers in many other localities; and it may be accepted as proven, that, where a means of educating beekeepers in diagnosis and treatment is provided for a period of years, either disease loses much of its power for harm. The means of education is usually a system of apiary inspection. Without such means, however, disease practically wipes out the industry, as it already has done in many localities in the United States.

However, the beekeepers on the western slope are fast getting in line, and most of the more extensive beekeepers are now in condition to cope with the trouble. They are now organizing county associations, having new inspectors appointed where needed, and are co-operating in a gratifying manner in the work. It is reported that from 5000 to 7000 colonies died of disease in one county in two years, due to unsatisfactory inspection; but this will not be repeated in that county at least.

It does one good to meet a crowd of beekeepers who, when asked how many colonies they have, give their answers in hundreds. We of the East too often confine our beekeeping efforts to five, twenty, or fifty colonies. Wherever the "hundreds" beekeepers are found in abundance it may safely be concluded that bee diseases will soon be controlled; but where the average is five, the problem of control is literally multiplied by thousands. It is also gratifying to hear the crop discussed in earload lots; for while the crop this year is light, the unit of measure is not changed.

I found in different parts of the State a number of beekeepers who were fearful that European foul brood would cause them serious losses. In one place a prominent beekeeper stated that he doubted whether there was a colony in the county which did not show some European foul brood during the season. In view of the fact that we had never had a single sample of European foul brood from Colorado, this was a surprising statement. I found on inquiry that, several years ago, a sample of discolored brood had been sent to an "expert" for examination, and he had pronounced it "black brood." This was before the name European foul brood was in use. Since the same condition is now widespread, and since the beekeepers were led to accept the expert's (?) dictum as gospel, the natural conclusion was that the disease now called European foul brood was widely distributed. The condition referred to is the so-called "pickled brood." No colonies have died of

the disease, which is enough to cause one to doubt the accuracy of the diagnosis; and when the symptoms of the prevailing trouble were described they did not at all resemble European foul brood. Such expert advice can not be considered as of extraordinary value to the industry. "To err is human," but before expressing an opinion in such matters one should consider the anxiety and expense that may follow the receipt of the reply. European foul brood may exist somewhere in Colorado, but no samples have so far been received from there by the Bureau of Entomology, and it seems probable that we should have received some intimation of the disease if it were present to any extent.

Several years ago the beekeepers of the State were instrumental in having a law passed providing for a county system of inspection, the inspector to be appointed by the county judge on petition of the beekeepers. County inspection is usually far from perfect, in that the inspectors in the individual counties do not co-operate. It is, too, not always possible to get a good man in each county to take the position, even if the various judges or other appointing officials were always anxious to appoint the best. It would be easy to offer other objections; but the same criticisms, or others just as weighty, might be offered against almost any system.

At the last session the State Legislature passed a bill providing for State inspection under the supervision of the State Entomologist. This is similar to the plan in several other States; and in such cases the results are highly gratifying. This has been the recommendation of the writer for several years; and it is pleasant to know that, in several States and Territories, the beekeepers have been and are of the same opinion as to the desirability of the plan, and that in seventeen cases it is in force to-day. It may be mentioned parenthetically, that in 1906 there were but two such laws.

Prof. C. P. Gillette, the State Entomologist, has for several years been interested in bees, and has written several bulletins of value to beekeepers. This is an increased assurance that his supervision will be for the best interests of the beekeepers. His deputy in the work is Mr. Wesley C. Foster, of Boulder, who comes of good beekeeping stock, and who counts his colonies in hundreds. Since Mr. Foster is so well known to GLEANINGS readers no further introduction is needed. Not being a lawyer, an expression of opinion is somewhat risky; but it looks from the road as if both laws were still in force, for the new law seems not to repeal the old. This is work-

ing out in a satisfactory manner in that the county inspectors are still at work, but the State Inspector can guide and direct the work in a harmonious manner, and step in to help where he's most needed. In fact, the State Inspector has declared his intention of working only in counties where county inspection is maintained. The State work could not be begun until August; but Mr. Foster has already made a careful study of conditions all over the State, and has spent several weeks in harness. It is too early to report on results, but it seems easy to predict that they will be good.

SOURCES OF HONEY.

Colorado is justly noted for its alfalfa honey. As is, of course, well known, alfalfa is grown in Colorado only under irrigation, and usually three crops are cut each season. If the alfalfa-growers would only cut their alfalfa to suit the beekeepers, Colorado would lead the country in honey crops; but the hay is usually cut just as it comes into bloom, except, of course, where a seed crop is desired. The increase now being made in the irrigated areas is naturally offering new locations for beekeeping; and if alfalfa remains a leading crop by the time the total irrigable area of Colorado has water on it we may look for train-load crops of honey. With the increase in the price of alfalfa hay, however, there is a marked tendency to cut earlier, and this has already hurt the honey crops. Cleaner cultivation and better care of irrigation ditches have already in some localities decreased the amount of sweet clover, which is a valuable addition to the honey resources. If Colorado irrigation water comes to be carried largely through pipes, as it is in parts of the West, the amount of sweet clover will be reduced with serious results to beekeeping. These factors are said to be largely responsible for the recent failures of the honey crops in northern Colorado, which have resulted in the shipping of several carloads of bees to new fields in Idaho, Texas, and elsewhere.

Every one knows that Colorado is celebrated for its deciduous fruits. This brings to the beekeeper a bountiful supply of early nectar; but colonies are usually not in shape to store any surplus, any more than they are in the East; so that, as elsewhere, the fruit-grower profits more by the work of the bee than does the beekeeper.

The Rocky Mountain bee plant (*Cleome*) is abundant; but at the places visited little mention was made of its being a main source of honey.

COMB HONEY.

Probably the majority of the beekeepers I met in Colorado are producers of comb

honey. Alfalfa honey is beautifully white, and the comb honey is certainly choice-looking. As an objection to the production of comb honey in an alfalfa region may be mentioned the fact that the honey granulates quickly. This is, I understand, true mainly after it is extracted, however. Furthermore the honey-flow is not excessively rapid, rarely exceeding a gain of five pounds per day, while three pounds would probably be a good average in a good season. The flow extends intermittently from some time in June nearly or quite to September 1, extending over the periods of the three cuttings of alfalfa. Such conditions would not appear ideal for comb-honey production to an eastern comb-honey man. However, the demands of the market seem to indicate that comb honey is more profitable than extracted, and most beekeepers seem to prefer it. There are exceptions to this general rule, so that Colorado differs not at all from the East in having arguments as to the desirability of each kind of honey production. There seems to be no hope of settling this question on this side of the Styx, so I refrain from starting an argument on the subject.

Washington, D. C.

To be continued July 15

THE RED FLOWERS OF NORTH AMERICA

BY JOHN H. LOVELL.

There are only 257 red flowers in our northern flora. Their hue is due to a soluble red pigment called anthocyan, dissolved in the cell sap. It is also of frequent occurrence in the stems and leaves of herbaceous plants, as well as on the under side of aquatic leaves and of radical leaves growing in rosettes, as in the mustard family. It is particularly abundant in early spring and late fall, and at alpine heights. It probably serves to convert light rays into heat, and thus aids the plant in its growth under cold skies.

Red anthocyan is always acid; for instance, when a red rose is dipped in a weak alkaline solution (ammonia) it becomes blue; but if it is then treated with a weak acid its red hue returns. In this way its color may be changed repeatedly. Red coloration is much more common in foliage than blue, because the cell sap is usually acid. We have undoubtedly here the explanation of the difficulty florists experience in their endeavors to produce a blue rose. The rose family exhibits a marked tendency in stem, leaf, bud, flower, and fruit to develop red coloring—a tendency due to the strong acidity of the cell sap. Of

the 148 flowers in eastern America, 4 are green, 82 white, 39 yellow, 19 red, and 4 dull purple; but blue does not occur at all. A blue rose will be produced only when a flower is obtained in which the cell sap changes from acid to alkaline. This actually happens in the common borage, the corolla of which is at first red but later turns blue.

It was long believed that the same species could not produce yellow, red, and blue flowers. But this doctrine, to use the words of Dr. Lindley, "must now be laid up in the limbo of pleasant dreams." This supposed law is contradicted by the hyacinth, pansy, cardinal larkspur, and many other plants. Though both red and blue coloring never occur among the wild roses, a hyacinth has been seen to produce a perfectly pink and a perfectly blue blossom on the same truss; another truss had blue flowers on one side and red flowers on the other, and several of the flowers were striped longitudinally red and blue. In the sweet-scented violet (*Viola odorata*) blue cells may occur above and red cells beneath.

It is a very common occurrence for white flowers to change to red, and every stage of this transition is placed before us by the rose family. White and red roses may occur on the same root, and white and pink flowers have also been seen on a single plant of the snapdragon. Several kinds of pinks are at first white, but later change to red. This change of color may be brought about by a strong stimulus, as when lowland white flowers are grown under the intense light of alpine heights, or are stung by gall-flies. When a white flower of the common thorn-bush is stung by a gall-fly, all the organs become bright red, and increase in size.

Mr. A. I. Root has already called attention in GLEANINGS to the violet-blue rose offered for sale by florists for the first time during the season of 1911.

There are a number of families in our flora in which red flowers are common, but blue is wholly absent. The buckwheat family contains 11, the orchis family 22, the rose family 19, the mallow family 13, the evening-primrose family 10, the heath family 10, and huckleberry family 11 red-flowered species; but there are no blue flowers in any of these families. While this is primarily due to the acidity of the cell sap, it will be noticed that most of the flowers are regular in form and but little modified. In other families, such as the pea, gentian, and mint families, both red and blue flowers are common.

There are many red lilies, orchids, and pinks, which are great favorites of butter-

flies; and, therefore, it was long thought that butterflies, at least the fire-red kinds, preferred red hues. But further proof seems desirable. Red flowers are most abundant in the pink family, which contains 22 species. The pinks exhibit a wonderful variety of red shades, varying through rose, pink, and deep red to scarlet and crimson. The petals may be dotted or marbled with white, and they are often notched or fringed, and surmounted with a corona of scales. The scent is aromatic, and the nectar lies at the bottom of a slender tube where it is often inaccessible to all insects except butterflies.

Trees with red flowers are rare, but shrubs are common. Of trees, the peach, red buckeye, and red maple are the best-known examples. There are many red-flowered shrubs in the rose, heath, and huckleberry families. Undoubtedly the two handsomest North American shrubs belong to the heath family. The are *Rhododendron maximum* and *Kalmia latifolia*, or the mountain laurel. Asa Gray says that in North Carolina they adorn the valleys and mountains in immense abundance and profuse blossoming of every hue from deep rose to white.

It is rather remarkable that, among the 571 species of *Compositae*, there are only nine red flowers. On the other hand, 13 species, or one-half of the mallow family, have pink or red blossoms. In the buckwheat family the petals are wanting, and the flowers are small; but the calyx is often red, and sometimes the seed-vessels, stems, and leaves. In the poppy family the flowers are crimson, scarlet, and yellow, and the sap is also yellow or red. The wild columbine (*Aquilegia canadensis*) produces scarlet flowers which are yellow inside but rarely all over. There are two other species in our northern flora which exhibit similar coloring. They are the trumpet honeysuckle and the Maryland pinkroot. The former is sometimes yellow throughout. All three of these flowers are visited by hummingbirds. Another hummingbird flower, the cardinal flower, is unsurpassed in the brilliancy of its coloring by any other red flower.

The number of red flowers which are valuable to the beekeeper is much smaller than those which are white or yellow. The most important are the peach, huckleberry, red and crimson clovers, and the great willow herb, or *Epilobium angustifolium*. In New Zealand thousands of acres of waste land are covered by New Zealand flax (*Phormium tenax*), which produces a beautiful red flower and yields a most delicious honey.

Waldoboro, Me.

FIG. 1.—Owl Creek apiary of A. B. Marchant, near Sumatra, Fla. But for some hard work in raising the hives up on empty supers this yard would have been lost. It was intended to fill the carload order for bees from this yard; but water made this impossible.

SHIPPING BEES BY THE CARLOAD FROM THE SOUTH TO THE NORTH

Migratory Beekeeping

BY E. R. ROOT

While I was at Mr. Marchant's in Florida, I engaged his son Ernest, who was his father's lightning operator at extracting, to come and work in our yards. The demand for bees last year was usually heavy—so much so that our colonies were comparatively weak—especially for so severe a winter. Along the last of February we sent Mr. Marchant down to his father's to bring back a carload of bees in three-frame nuclei. We had figured that we could put 500 such boxes of bees in an ordinary car. Nucleus boxes, including the queens, were shipped in the flat by freight, nailed up in Florida, and after the bees got to breeding well the boxes were filled with bees and brood. On the 6th of May the bees were loaded on to the boat at Patrick's Landing, and then carried up the river to Bainbridge, where they were put in a car for Medina.

Unfortunately for Mr. Marchant there were heavy rains and floods throughout the entire South, particularly in the Appalachicola region. The Owl Creek yard, from which the senior Mr. Marchant expected to make up this order of 500 nuclei, came near being drowned out as will be evident from Fig. 1, which view was taken when the water was at its greatest height. A. B. Marchant is seen at the left, and Ernest Marchant is at the right. It appears that

they had a strenuous fight in saving the bees. This they did by raising the hives up on supers to keep them out of the water, for the hives were already on hive-stands that raised them 18 inches off the ground. The water kept rising until the gasoline launch was called into play to help out. It was impossible to make any general landing, and hence our order for nuclei was filled from another yard. The first carload arrived on the 13th of May, being just a week on the road. The bees were loaded into an open cattle car, one tier being placed on a framework just above the floor to secure bottom ventilation, and another tier about four feet above the first tier. In the center of the car was a little space for a cot, some bedding, a barrel of water, a bee smoker, several sizes of big nails, and a heavy hammer. Mr. Marchant was supposed to ride in the caboose; but the weather was so changeable that he took up his headquarters in the car with the bees.

When the bees started it was insufferably hot, and they needed sprinkling. Then it rained; and when the car almost reached its destination a fall of snow came on. The result was that Mr. Marchant was kept busy in shading the bees from the sun with strips of muslin which he carried with him; next changing the muslin to cut off the wind and the rain, and finally throwing the muslin over the tops of the hives, including all his bedding, to keep out the snow and cold. He had all conditions of temperature from 100 in the shade down to freezing; and as he relates his experience he says the common cattle car, to put it mildly, is no "Pull-

FIG. 2.—Empty three-frame nucleus shipping boxes that were used for the carload. Note that the boxes are made of light thin stuff, and screened top and bottom.

man." I said to him, "Why didn't you ride in the caboose, Mr. Marchant?"

"I did not dare to," he said. "The railroad people gave me an old rickety cattle car that I was really afraid would fall down on me."

Whenever he saw it was beginning to give way in places he put in additional braces and plugged in more nails. Next the bees would need water. Then they had to be screened from the cold winds at night. The result was he had to be up and doing almost night and day.

"No, sir," said he, "carrying 500 nuclei in an open cattle car 1400 miles is no snap. One has to secure his dinner on the run, grabbing up a sandwich or pie between stops. When the car was changed from one division to another I had to beg and almost threaten the conductor and his crew to get them to take my carload of precious freight in the next train that pulled out. They would tell me that the car could wait till the next day—that they were too busy, etc. I told one conductor he *had* to take the bees or there would be trouble."

FIG. 3.—Three-frame nucleus shipping boxes filled with bees. The screen tops (with the convenient cross-rail for a handle) are secured to the nucleus box proper with two screws at each end. Such boxes are very handy for moving bees, either for shipping or carrying from one part of the yard to the other. They are also very handy for carrying combs.

FIG. 4.—Wagonload of 91 nuclei *en route* to the Basswood yard. A low-wheel wide-tired wagon is just right for loading and unloading, and for carrying bees from one yard to the other. The wide tires make it possible to get over soft sod when the ground is wet. We use this wagon with the team. We also have a light spring wagon and a horse for small loads.

While railroad men are used to handling perishable freight, they seem to think bees can lie over awhile and cool off, and that it would be better for them.

In spite of the extremely hot weather, in spite of the cool nights, and in spite of the snow, rain, and hail, the bees came through in splendid order. Not a particle of brood was destroyed, and, so far as we can discover, all the unsealed brood was left intact. More remarkable still, the queens kept on laying in spite of the bumps and jolts and the changes in temperature. When the bees were unloaded at Medina we found young brood in all stages, and eggs, while a good part of the sealed brood had been hatched; for it is a well-known principle in shipping bees that it is always advisable to send only *sealed* brood. Unless the bees are watered they will lick up every particle of unsealed brood.

But Mr. Marchant prevented this by watering the bees three or four times a day. This was done with a watering-pot, spraying water right on the wire cloth. The frequent sprayings, he thinks, prevented the bees from destroying their unsealed brood, as they usually do when sent by express in the usual way. Not only did the bees continue to rear brood, but some of

the queenless nuclei kept on cell-building; and when they arrived there were several that had virgins running loose; and when they had no opportunity to fly, there seemed to be no disposition on their part to fight, on the principle of the survival of the fittest.

Still again, there were several nuclei that had caged queens; and in every one of these the queens were released, and in some cases had laid eggs. All together, I think this was one of the most successful shipments of bees ever made. Briefly stated, the secret of that success was in giving the bees plenty of water as often as they needed it, ventilation top and bottom, and protecting them from the hot sun, and, I might say, from the wintry blast at the latter end of the journey; for it will be remembered that considerable snow fell here on the 12th and 13th of May.

Let us now take a look at the nucleus boxes themselves; for no small part of the success was due to the style of the carrier. The reason we decided on three-frame nuclei was to get a large number of queens and frames of bees and brood with as little weight as possible. In Fig. 2 the construction of the carrying-box will be apparent. The ends are made of 7-16 lumber, while

FIG. 5.—Taking the bees out of the nucleus boxes and putting into the hive. These boxes of bees are just right for strengthening up weak colonies in the apiary.

the sides are 3-16 and nailed on to the ends. The ends of the top-bars of the frames rest on notched cleats. The bottoms of the end-bars are held by similar notched cleats nailed crosswise near the bottom on the inside of the ends. The under side of the nucleus is covered with wire cloth, and below this, about half an inch, is a false bottom of wood. The top of the nucleus is made with gable ends with a cross-cleat, that is used as a handle in picking up the nucleus boxes. Besides the hand cleats are two strips of 3-16 lumber that hold the wire cloth. A couple of cleats at each end securely fastened to the cover hold the frames in place; and when this cover is secured it is impossible for the frames to shuck up and down or against each other.

In Fig. 3 we show the nuclei filled with bees, ready to load on the car or wagon.

Fig. 4 shows 91 nuclei loaded on to a wagon with small wheels and wide tires. This was the first load out of the car, *en route* for one of our outyards. The advantage of *low wide-tired* wheels in loading and going over soft ground in going to the beeyard in the back lot will be apparent.

On arrival at the yard one nucleus box was placed by the side of each one of the empty hives. Then the boys went around,

opened up the hives, lifted out the frames of bees, and put them in a hive on their permanent location. This was followed up two days later with frames of empty combs for queens to lay in.

This shipment of bees arrived just before the opening of fruit bloom, so that they were able to gather honey that amounted to nearly the cost of the freight on the bees; for honey from natural sources will do more to stimulate the rearing of brood than any thing that can be done in the way or artificial feeding.

So successful was this shipment of bees that we sent back this same man, Mr. Marchant, to his father's place for another carload; and a telegram just received informs us that they started to-day, May 27.

We expect this carload of bees to reach us in time to catch our northern clover and basswood. If we have any kind of flow, the honey secured should go a long way toward paying for the cost of the bees, and at the same time leave us the bees and the queens to supply hundreds of beekeepers who have lost heavily during the winter.

The first shipment of bees was loaded on to a boat after the main honey-flow from tupelo was over. The idea was to utilize the bees in Florida until the flow, and then

Mr. Beaudin's residence, with apiary in the background.

ship them north to catch another flow. The first car was to reach the fruit bloom, and the second car, if nothing unusual happens, will be here in ample time to get in good shape to catch the basswood and clover.

MIGRATORY BEEKEEPING.

Migratory beekeeping has not been practiced to any extent in the United States. One difficulty is that our distances are so great, and the freight is so high, that most beekeepers lack the nerve to try it. Quite a few beekeepers in Northern Michigan have managed, however, to catch their clover and basswood, and then move northward by car to catch raspberry and fireweed. It is my opinion that migratory beekeeping might be practiced to more advantage than it has been.

Just now the beekeepers in some western States are moving their bees by the carload, after they secure one crop, into California to catch the alfalfa or sage that comes on later. At this writing, May 27, it is stirring up a hornets' nest, or, rather, a bees' nest, among the California beekeepers, who fear the introduction of disease, and who complain that their territory is already overstocked. The fight is on, and how it will be settled remains to be seen.

A SUCCESSFUL FRENCH CANADIAN BEEKEEPER

BY A. L. BEAUDIN

In April, 1893, I bought my first colonies of bees, a copy of the A B C of Bee Culture, and Dadant's Langstroth. Since then I have bought many colonies as well as a large quantity of honey. In 1910 I increased from 180 colonies in the spring to 256 good colonies in the fall, and took 26,000 pounds of extracted honey and 256 pounds of wax from cappings. All of the bees were in one apiary, and in nine-frame Lang-

stroth hives. I have one capping melter and one six-frame automatic honeyextractor with a one-horse-power gasoline engine for driving it. I am much pleased with the outfit.

In the fall of 1911 I took 10,000 pounds

A. L. Beaudin, the French Canadian who increased from 180 colonies to 256, and extracted 26,000 pounds of honey.

A. L. Beaudin's 250-colony apiary at St. Chrysostome, Quebec, Canada.

of extracted honey from 170 colonies, and 120 pounds of wax from cappings.

The Universal Simplicity feeder, which I invented, is a feeder *par excellence*, as it can be adapted to all styles of hives, and one person can feed 200 colonies with it in 30 minutes, without disturbing the bees. The size is 6x12 inches, and 5-16 high, with capacity of about 10 ounces. This feeder is made of tin, and in order to secure the best results it should be exactly plumb. I have used it about 12 years without adapting it until recently to different sizes of hives.

St. Chrysostome, Que.

BOOK-KEEPING NECESSARY

A Book for Each Kind of Record to be Kept, Better than One Unwieldy Volume

BY LEO ELLIS GATELY

In any successful business, operations must be mathematically evolved and systematically conducted. It should, therefore, be apparent that, if the apiary is to be put upon such a basis, no hit-and-miss practices can be tolerated in record-keeping.

In both books and publications on bee culture, this matter appears to draw forth scant discussion; and what is found seems intended more to arouse interest in the sub-

ject than to outline any formulated plans or up-to-date methods. If an improved method is given, the chances are that its supposed superiority will be based chiefly upon the doubtful grounds of ease and rapidity, with an utter disregard of the more essential features of accuracy and permanency. Would it not be far better to devote considerably more time and patience to a precise and comprehensive system?

In an endeavor to keep a complete record of all that transpired in our apiaries we struggled for years through oceans of marks, tags, and memoranda, testing about every scheme in existence. This labor would, in fact, often assume such proportions as seemingly to overshadow all other duties. There are, no doubt, plenty of others now making a similar mistake.

When unimportant details keep one until so late at night that the big things get put off till some future time, there is room for improvement in that system of accounts. Neither it is always neglect that tangles balances and reports. Instead of one bulky volume in which to enter tiresome memoranda, an endless amount of bookkeeping drudgery will be eliminated if a complete set of small ones is kept, divided and subdivided into all necessary departments. These may bear such distinctions as:

Day-book; weekly queen-rearing; month-

ly bought and sold; annual colony-record, and such others as the requirements may demand. The pages of these are ruled off, and in the separate spaces headed according to the character of the record being kept. The annual colony-record will, for instance, be headed at the top of each page, something like this:

Date; number of colony; kind of hive; queen—age; supers, given—removed; honey—lbs.; feed, cost; variety of bee; gentleness; swarming; supersedure; capping; rating; colonies on hand.

With such a set of books it requires but a moment to enter *permanently* the full details of any operation or transaction; and it is then possible, for all years to come, to know at a glance exactly what each colony has done or is doing. While it is well to use some system of temporary hive-index, with tags or their equivalent, records are lost with each change that may be a daily occurrence, and can never become more than a minor part of any well-regulated recording system.

As the majority of beekeepers are now beginning to take great pains in making careful selections for breeding stock, it is now, as never before, becoming necessary not only to watch the progress of the hatching cells, but to make some definite and lasting record of the yield and general char-

acteristics of individual colonies; for otherwise there will be no possible means of determining which are really superior, as the colony that last year did so splendidly may this season prove an utter failure, or the reverse. The importance of keeping such records in permanent form should, therefore, be obvious, as it is an established fact that one summer is wholly insufficient to prove the true value of any queen.

Ft. Smith, Ark.

ORTON'S HOME-MADE SAW

Further Particulars Regarding it

BY PERCY ORTON

Ever since you published the description of my home-made foot-power saws, p. 627, Oct. 15, 1911, I have been besieged with letters asking about the details of their construction. The two illustrations of the better-working saw of the two I made give dimensions, etc. Many refrain from making a start with bees on account of the high price of factory-made hives. Those who are ingenious, and have plenty of good pine lumber, and a cheap home-made buzz-saw, can easily make good hives.

The frame is 3x3 hard wood, 32 inches high, 34 wide, 39 long. The 30-inch drive-

Detail of construction of Orton's home-made foot-power saw.

The table raised, showing saw and mandrel beneath.

wheel should be of iron, with either a three or four-inch face. It may be a plain wheel or an old mowing-machine wheel "trued up" by a machinist. The ball-bearing hangers are from an old grindstone.

The 8-inch saws should have a hole for a one-inch shaft, and should be very thin, like those used on the Sears & Roebuck foot-power saws.

My mandrel came from Sears & Roebuck. The length of the 1 1-16 shaft is $16\frac{1}{2}$ inches; the diameter of pulley, $2\frac{1}{2}$; face, $3\frac{1}{2}$. The whole mandrel, including the pulley in the center, cost me \$3.53. I use a canvas belt; but any belt $1\frac{1}{2}$ to 2 inches wide is suitable.

The table was made from the leaves of an old extension table. It is hinged at the back, and raised and lowered by the screws in front of the drive-wheel.

This is a homely machine, but it runs easier than a No. 4 Barnes saw that I own,

or a Sears & Roebuck that a neighbor of mine has to do carpenter work with.

Northampton, N. Y.

ADVOCATING A STEP BACKWARD IN BEE-KEEPING

BY WALTER S. POWDER.

In all the different branches of agriculture there is none quite so interesting and fascinating as beekeeping; and thousands are making their first efforts for a start annually; but when we follow them in their trials and hopes we find a very large part of failures which should not happen. Just as long as this condition exists we know that there must be something lacking in our books and magazines, and in the teachings that are being followed. I have met with hundreds of instances where extravagant outfits of supplies were secured, a

year or two of pleasure and hope, and then all were discarded as a failure, while the same amount of money invested in honey would have supplied the family for years. Just as long as these conditions exist we are forced to admit that there is something wrong with our industry. There is a demand for simplicity, and safer promises for returns from investments; and we have drifted into a system of manipulating hives that has become standard and yet not up to requirements.

The beginner has the impression that he must secure the very latest equipments described in the catalogs, believing them necessary because in general use, and it seems that all of us have reached this same conclusion. We discarded the two-pound section long ago to adopt a standard pound (?) section to meet commercial demands; but to-day we have no section of comb honey weighing, uniformly, a pound to the section. We admit that bees stored more honey in the larger section; but we sacrificed it for the smaller, it being most in demand; but it is still a question whether the quantity produced would not have increased the profits for the producer. We all *think* we must use separators or fences in producing comb honey, and yet we know that any plan that divides the cluster during comb building retards the progress greatly. Our seasons for surplus honey are short at the best; and how disappointing to close the season with a few small unfinished sections between separators, when, with different and more simple equipment, results might have been more satisfactory! I sometimes think that the beekeeper known as the "old-fogy type" is ahead of his "up-to-date" competitor when I see the results. For instance, the man who produces comb honey in shallow frames or full-size brood-frames, and then cuts it out, adds some extracted honey, and puts it up in a neat container with his label. He would not consider sections or separators, has less swarming during the flow, his product is always in demand, and the method paves the way for safe winter preparation.

The demand for broken comb honey or bulk comb honey is excessive, and is increasing. One can produce both comb and extracted in the same yard; and with the same equipment the quantity of comb produced on this plan will be much greater than what could be secured in sections where clusters of bees are divided. Some will say that the objection would be granulation when put up. Comb honey that has not been bruised in shipping will keep a long time without granulating, and packages could be put up as required, always fresh

and clear; and even if some did granulate we begin to know that granulated honey is not to be snubbed. There is a most excellent illustration of this method in Texas. Texas is a large producer of very fine honey, and yet we do not hear of Texas honey on our overstocked markets. The reason is, they have learned how to create a home demand for their product; they have a good thing, and they use it themselves. I am informed that every family, rich or poor, has a can of broken or chunk honey in the house. It reminds me of the story of the traveler at a hotel. He ordered an extra-tender porterhouse steak and accessories; but the waiter halted him with the remark that, if the boss had a steak like that in the house, he would eat it himself.

Beginners become confused about hives as to wintering qualities, and should be impressed through books that a strong colony with an abundance of stores will survive in almost any kind of hive. The severe losses of the past winter can almost be traced to lack of stores—bees simply starved to death, but often in the midst of plenty. If bees were overfed in fall it would add much to their safety in winter, and they would produce surplus earlier the next season if the brood-chamber were well supplied.

Indianapolis, Ind.

SWARM PREVENTION

Three Methods for Effecting it by the Use of Large Hives

BY GARRISON H. ADAMS

There are several good methods of keeping bees from swarming. The best is one which I have used to a great extent for 25 years. Others are using it upon my recommendation, and find it a great success. It is simple, and easy to carry out, with very little work. The hive must be the right size. The one which I use I call my non-swarming hive. First, the beestand is made 18 inches wide and 28 long, of two pieces of 2x4 hemlock studding. The stand boards are nailed to these at its ends. The whole thing is then placed on four bricks which make it nearly 7 inches high.

The hive, outside measure, is 13 inches high, 14 wide, and 25 long. The brood part contains 16 frames about the same size as the Gallup. All of the frames must be used for the brood, and a good queen will fill nearly all of them early in the season.

The frames are made very easily and cheaply from $\frac{7}{8}$ white-pine lumber. The top and bottom bars are one-half inch thick. The sides are the same width, but

made one-fourth inch thick. The projections of the top-bars are eight-penny wire finishing nails. Frames made in this way are more durable. The bees do not stick them fast, and they cost less. The frames run crosswise of the hive. I make the hives so that there is one-half inch above the frames, and a little more than an inch below in the brood part. In the upper hives there is $\frac{1}{2}$ inch above the frames and $\frac{1}{2}$ inch below. The entrance is made in one of the ends of the brood part.

The comb-honey super has wide frames the same size as the brood-frames, except that they are two inches wide, and they are made in the same way with two wooden separators 5-16 inch thick and 4 inches wide, nailed to one side of the wide frame.

The sections are $1\frac{7}{8}$ inches wide on all four sides. A wide frame will hold 6 one-pound sections when well filled with honey. The sections will be longer up and down than they will be the other way. One super will hold 10 wide frames with 60 sections, or 12 extracting combs.

As a rule I have used the hive three stories high, and have not had a swarm from them in 25 years. During that time I have had but one swarm from two-story hives.

It is quite an easy matter to coax the bees to work in the sections in this hive by placing an extracting comb in the center of the comb-honey super. Comb and extracted honey can be easily produced in a hive of this kind at the same time. A section of honey can be removed as soon as sealed before the bees soil it by running over it. I have often had the two upper stories filled solid with sealed honey, and yet the bees did not swarm.

This hive should be ventilated at the bottom, when the bees are out of the hive, by putting a piece of thick lath under each front corner of the hive. This will give the bees a two-inch alighting-board on three sides. Shade the hives if they stand in the sun.

BY INTRODUCING YOUNG QUEENS.

In order to prevent swarming when small hives are used, all that is necessary is to remove the old queens and introduce young ones that have just commenced to lay. These small hives can be packed with sealed brood, and the bees will not swarm during the whole season, whether running for comb or extracted honey. These queens, too, as a rule, lay better than older ones. I prefer to raise the queens myself, and then I know surely that they are young, as this makes all the difference in the world. It is quite an easy matter to have a lot of choice and vigorous young queens reared by the time the swarming season begins. If the bees

have been properly wintered they should with good spring management be strong and vigorous in early spring, and the young queens reared from such colonies will be prolific. I have never had a swarm when I have used this plan. If the bees cluster out on the front of the hive, raise the hive and put a piece of thick lath under each of the front corners, and give more surplus room above, and shade from the sun. I keep plenty of thick spruce lath in my apiaries, and find it useful for many purposes.

Perhaps some one may wonder what I do with the old queens that are to be removed from the colonies. If the queens are good layers a place can be found for them. For instance, the old queen and two of the poorest combs of brood in the hive may be removed, together with a few bees, and put in another hive of the same color. The queenless part can be moved to a new stand some distance away. Put the hive containing the old queen and the two combs of brood with a little honey in the two combs on the old stand, and fill out with empty worker combs or frames of full sheets of worker foundation. All the field bees will return here; and by buckwheat time this part of the colony will be ready to gather surplus from this source if the season is a good one, provided they have been given proper summer management.

After two days, fill out the queenless part with large combs of brood about ready to hatch, and introduce a young queen that has just begun to lay. She will be gladly received by the bees. If honey is coming in, put on the super for either comb or extracted honey. The colony will not swarm that season; but extra ventilation may be necessary at the bottom.

BY REPLACING COMBS OF BROOD WITH EMPTY COMBS.

At the swarming season, when the bees are very strong and seem ready to swarm, open the hives and remove from each four or five of the best combs of brood almost ready to hatch, and destroy all queen-cells which are not needed elsewhere. Shake off all the bees from the combs into the hives. Care should be taken not to lose the queen. Fill out the hives, from which the brood was taken, with empty worker comb or frames of full sheets of worker comb foundation, alternating until the hive is full. Ventilate the hives at the bottom by putting a thick piece of lath under each corner at the front, and give plenty of surplus room at the top. Any colonies treated in this way will not be likely to swarm. Shade the hives if they stand in the sun.

The combs of brood taken can be given

to colonies having young queens just commencing to lay. Colonies having young fertile queens can be given a large amount of brood. You can fairly pack it in, and they will not swarm—at least this has been my experience for the last 34 years of continuous beekeeping.

This last method, combined with the second one, will keep bees in small hives from swarming, and both should be employed at the same time, as they are dependent on each other.

Troy, N. Y., March 26.

SHALLOW DUMMIES IN TEN-FRAME HIVES

Contracting the Brood-nest without Causing Swarming

BY LEON C. MILLER.

I have been using slatted dummies in my ten-frame hives the last two seasons, and find them a decided help. I have not tried to use them with the idea of stopping swarming entirely, but mainly to contract the brood-nest without causing the bees to swarm. I used them quite extensively this way last summer.

When the time comes to put on the comb-honey supers I go to the hive and remove any empty combs there may be (by empty ones I mean those not fairly well filled with either brood or honey). There will seldom be more than one or two, and many times none of these in the hive; but what there are I don't want left in there to furnish a place for the bees to store the honey that I want in the comb-honey supers. These I replace with the slatted dummies, and I find that bees so treated are no more inclined to swarm than those that are allowed to have their full amount of combs. On the other hand, if I put the ordinary solid dummies in the place of one or two combs it makes the hive just that much smaller, and just in that proportion has an effect in the tendency of the bees to swarm. Later, if I find it necessary to shake a colony I put the bees on about six frames of foundation, and fill the rest of the hive with these slatted dummies. A comb-honey super, filled with full-sheet foundation and bottom starters, *a la* Miller, or, better still, if there is one already partly filled from the colony before shaking, will make the work go on apace.

I think I shall try a few colonies this summer with two hive bodies, the frames alternating with the slatted dummies as described by Mr. Small on page 278, 279, May 1. I am not very enthusiastic about it, however, as I am of the opinion that bees work-

ed on that plan will not go above as readily as they should. I know they will not in a hive arranged that way without the dummies, for I have tried it. I experimented with a few hives that way one year; and when they had two stories fairly well filled I put on the supers; but instead of going right into it, as I expected them to do, they seemed to think they had honey enough, so they rested on their oars; and the consequence was I got very little honey those I worked on that plan. It may be that, with the slatted dummies, the queen will keep the frames better filled with brood instead of allowing them to be filled up with honey as they did for me, and this will have a tendency to force them up into the sections more. At least it is worth a trial, as I have plenty of the dummies on hand, and will not have to go to any extra expense.

I don't think it would pay any one to go into this plan of mine on a large scale, even though it might be a success, for I think it would be cheaper and much more satisfactory to buy the Aspinwall hive complete. But sometimes one might have the other equipment, and would not like to buy a whole new outfit, but would still like to make use of this principle. In this case I think it would pay very well either to make up or to hire made some of the slatted dummies to be used according to the plan I have outlined here, or as Mr. Small uses them.

Barryton, Mich.

FELLOWSHIP AMONG BEEKEEPERS THROUGH ORGANIZATION

BY HENRY REDDERT.

I received a letter from a beekeeper in Oklahoma in which he says, among other things: "I understand, after only two years' experience, that beekeepers are good brothers. I should like to get deeper into their fellowship." It sounds good. He is welcome. The first thing to do is to organize a beekeepers' association in his vicinity. Here is where good fellowship begins. Every county in every State where beekeepers dwell should have an association. Here is where they can make themselves at home, and a good home is the seat of good fellowship. Questions pertaining to beekeeping in all its phases may here be discussed at leisure. Good humor should prevail at all times.

In every country and clime where good men and women keep bees, good fellowship exists. This is an unwritten law. In a small town there is no need of a public hall to meet in. Halls are expensive. As little expense as possible should be incurred at

the beginning. In time if the association grows, which no doubt it will if managed properly, larger quarters may be obtained. At present any one's home will be a good place to hold a meeting, especially in small towns where everybody knows every one else. One meeting at one house, then in another, and so on as often as preferred, until each beekeeper's home has had a meeting, then starting again at the first one, works well.

Forage should be one of the chief topics discussed. Bee diseases, climatic conditions, the number of hives to be accommodated in a certain district, the different clovers best adapted to a given locality; honey-bearing trees, shrubs yielding nectar, various kinds of grapes, raspberry, blackberry, and honey-producing vines for shading porticos, laws governing the industry, and sweet clover sown in waste places, are all topics which should be considered. Each member should pay monthly dues for the maintenance of the association. A president, vice-president, and secretary-treasurer should be elected by the beekeepers; also an executive committee consisting of four or five members. Articles from bee journals may here be read and analyzed. The secretary is the business agent of the association. Through his energy and good will, many new additions can be made from time to time. From the president down, each one should do his part in booming good fellowship. Petty jealousies should be laid aside, and mutual assistance should be the slogan. With this in mind, good fellowship eventually will rule the beekeeping world. Cincinnati, Ohio.

SEVERAL INSTANCES WHERE STINGS RELIEVED RHEUMATISM

BY S. S. TALBERT.

I have read with interest the arguments, pro and con, in regard to the cure of rheumatism by stings. While I have never had any experience of my own, I have kept bees in a small way for a number of years, and have observed the effects of stings administered to others.

In the spring of 1909 a friend of mine was so badly afflicted that he could hardly walk, taking not more than about six inches at a step. His fingers and toes were badly drawn out of shape, and he was a good subject to work on. He had heard something about the bee-sting remedy, and asked me to apply it; so one morning I caught a number of bees, and we went to the office of Dr. Smith, of this place, and I applied stings to the patient in the places indicated

by the doctor (he keeping at a safe distance). We applied 24 stings on his feet, knees, shoulders, and hands. It made him very sick for a while; but on the Wednesday following, to every one's astonishment he could *run*, and went to his work that same day. He was perfectly cured, and remained so for two years, when it became necessary to repeat the treatment. We again used the same remedy, only we gave him a larger dose. As soon as the soreness from the stings was gone the rheumatism was gone with it. This man, Mr. Homer Parker, offered a number of times to write a testimonial to any one wanting it, but on January 28, 1912, he died of heart failure, following a bad siege of rheumatic fever.

The cashier of the Brownsburg State Bank had been suffering from rheumatism for 20 years. Two years ago last winter he got his *nerve* and *will power* screwed up to where he thought he could try the stings; so one day, when the bees were flying, I caught some and applied about 20. It made him very sick; but when the effects wore off, his rheumatism was gone.

I don't think any one should apply the stings except when there is an attending physician, as it seems to have a depressing effect on the heart; but I think any one taking this treatment should take enough to get a good heroic dose of it. I have never known any beneficial results to follow an application of two or three stings.

Another case that I have happened to know about where the pain was more localized than the ones I have just described, was a resident of this place. He was affected in the knees and ankles. I applied six or seven stings to his knees and ankles. It relieved him within a few days' time.

No. 4, another man of this place, had rheumatism in his feet. I applied five stings to each foot. After the inflammation from the stings was gone, the rheumatism had disappeared.

For the benefit of any one wanting to try the cure, I will say the best way I have found to handle the bees is to drop them into a basin of water; then with the thumb and fore finger you can pick them up by the wing, and your finger and thumb nail will protect you from the sting.

Brownsburg, Ind.

[We wish to repeat the caution given by our correspondent in regard to the importance of applying the stings to the patient when a physician is present; for it is a well-known fact that certain persons are so constituted that it would be dangerous to get as many as twenty stings at once.—Ed.]

Heads of Grain from Different Fields

A Bee-tent on Wheels

As I read Mr. Byer's article on finding queens, Oct. 15, p. 619, I fully sympathized with him in the task of examining 280 hives, finding five queens per hour—56 hours' work under a tent and on his knees. He and perhaps others may like to know how they may work more comfortably. I built a tent for this purpose, upon the axle of a pair of old buggy wheels, using a light frame covered with wire screen. The wheels carry the weight of the tent, so that I made it 3½ ft. wide, 6 ft. long, and high enough to enable me to stand upright in it. I fitted a wide shelf at the wheel end of the cage for tools, supers, etc.

At the door end, opposite the wheels, I hung curtains which could be fastened together while at work, or opened for the purpose of drawing the cage over a hive. The size of the tent gives ample room for work, and requires no getting on one's knees, creeping under the tent, depending on some one else to pass in tools or supplies, as every thing needed can be carried on the shelf.

I made the tent tight at first, but found trouble from the gathering of bees from different hives; so I made escapes by prying the wire cloth from the frame at intervals along the top, inserting pieces of lath to hold it open. The bees readily find these openings, while robbers busy themselves only around the sides, near the level of the tops of the hives, where they can obtain no entrance. A few get in at the doorway when the wind blows the curtains open; but finding themselves imprisoned they are more anxious to get out than to create disturbance.

The frame of the tent is about 8 inches from the ground, in order to clear clumps of grass or other small obstructions. The first season I thought I had to hang a curtain around the bottom, reaching to the ground. I have not found it necessary this year, although robbers have been on the *qui vive* for any point exposed.

Nearly every blacksmith shop and many farms have old buggy wheels and axles which may be obtained for this purpose. The framework need be only of 1x2-inch lumber, and screen wire is reasonably cheap, so that such a cage or wheeled tent is inexpensive, and the comfort of being able to stand upright while at work is worth all the labor and expense of making. Then when coming out of the tent the operator is not in the midst of the robbers, but several feet behind the hive, with his

head elevated above their line of attack, and not so liable to be punished for his doings.

The tent stands ready for use at all times, and I find it convenient in queen-raising to be able to go into it for operations which otherwise would have to be performed in the workshop. A waterproof cover would make it still more convenient in times of sudden showers.

How to Ship Bees; Water and Stores En Route

What is your experience in shipping colonies of bees long distances by water, Mediterranean ports to New York, for instance? Should they be supplied with candy or with honey? Are losses of bees likely to be heavy? Will sealed brood prove any disadvantage? In theory I believe that the frames should be filled with candy instead of comb and honey, and that they should be supplied with water; but I have had no experience along that line.

Lansing, Mich., May 20.

A. M. CLARK.

[Bees can be shipped by water as well as by rail with this difference: Transportation by the former is very much slower. Usually bees can be shipped by boat for very much less, for a given distance, than they can be sent by car; and where bees are not to be put out longer than a week or ten days we would ship by water, providing there was any object in the freight rates.

Sealed stores are very much better for shipping bees than any form of candy that you can use. We have tested out the candy very thoroughly, and our experience in shipping thousands of nuclei all over the United States shows most conclusively that natural stores of the bees (or, rather, sealed stores of sugar syrup or honey) are to be preferred to any candy that was ever devised.

Yes, it is very important that bees be given plenty of water on the route, but usually it is impractical to give it unless they go in a carload with a man accompanying. It would be unwise to ask the ordinary expressman to water the bees, as he would overdo the job and probably kill them. When bees go by express they have to depend upon the stores they get in their regular combs, unless they are shipped in pound and half-pound packages. In that case we necessarily have to give them candy.

In shipping bees it is very important to put in the hives only sealed brood. The unsealed, unless

the bees are frequently watered, would be destroyed, as they will take up any moisture in the combs in lieu of water. We give quite full particulars on shipping bees in our June 15th issue, page 422.—Ed.]

A Device for Stopping Robbing Immediately

No device or method that will stop active robbing instantly and satisfactorily has been introduced to the beekeeping world. The spread of foul brood increases the danger of robbing, multiplies its hazard, and makes the need of a good combatant or anti-robbor device more urgent than ever.

Years ago I gave this matter attention. Time, with occasional experiences, has gradually unfolded to me a simple and effective remedy.

The device stops warring colonies immediately, and prevents the usual killing of bees. It neither encumbers the combatants by contracting the entrance nor by sprinkling with nauseous or poisonous liquid. Under such excitement bees need plenty of fresh air.

The entrance is to be placed against the entrance of the hive, and the other open end projects over and outside of the bottom-board. I fasten mine in case of robbing with screws or nails to the hive; but of course this method could be improved.

In a case where many bees rob a colony, and can not get in because of the device, they will soon go underneath at the end of the bottom-board, and with persistent efforts will press up and bulge in the wire gauze from beneath; and, if not securely fastened, the whole thing will be lifted up and give them access to the inside. But no matter how many bees are robbing inside, they will and must all pass through the device in order to go outside, and they will do it—in a hurry too. Then in three or four minutes the rightful inmates will be masters of the field, and will again guard the entrance. As soon as peace and order are established, the device is, of course, removed, and the entrance may be contracted if necessary; for, although bees never leave their home while the battle is going on, they soon resume their flying afterward, and then the device would prevent their return.

Escondido, Cal.

L. F. LEONARD.

A Stampede for the Pollen of Wild Carrots

Of our common roadside plants the wild carrot is only occasionally visited by bees. I do not remember ever having found a bee searching for nectar over the broad white umbels, and usually the yield of pollen is rather scant. Its apicultural value is, therefore, slight in this part of the country. It is not to this which I wish to call attention, but rather to that well-known trait of the bee, the habit of confining its labors to some one particular species, to the exclusion of every thing else for the time being, though there may be other plants in bloom at the same time, apparently just as attractive. An illustration of this came under my observation the past season.

About August 20 I found that my bees had run a line to the north of the yard; and, being too early for buckwheat, I was uncertain as to what the attraction could be. I found the line headed for a good-sized field covered with a dense mass of white bloom. Getting closer the blossoms proved to be those of wild carrots. The plants had all come up after having been mowed previously in the haying. Each cut-off stem had sent out a number of branches all about the same height from the ground; and

these in turn had each borne a small cluster of blooms.

It was a field of carrots to the exclusion of every thing else. The bees were there by the thousand. They were apparently getting pollen only. In doing this they scampered in a lively way among the florets, flitting from one cluster to another until the greenish-white pellets were completed and the start for home was made.

Scattered along the roadsides and in old fields elsewhere, innumerable wild carrots were growing, the flower clusters on which were uniformly much larger than those to be found in this field of perhaps ten acres. It rarely happened that a bee would be found on one of the plants outside of the field in question. There were no aphides in sight, and nothing to indicate the presence of honey dew. Apparently the ease with which the pollen could be gathered, from the close massing of so many blossoms, would naturally seem to be the best explanation for the general behavior of the bees.

At the time of the preference for the carrots, the bees had been visiting five species of mints besides climbing hempweed, jewelweed, and two species of *Eupatorium*—plants all regularly visited. These, however, were all abandoned in the stampede for the wild carrots.

Aiken, Md.

J. FORD SEMPERS.

Can Bees Recognize Playing-cards?

It may not be known generally that a deck of playing-cards would play an important part in mating young queens, so here goes the kink. I take any card in the deck, except the pictures, and tack it close above the contracted entrance of a nucleus for a sign-board; and when the queen takes her wedding trip she notes that particular sign, and never fails to return to the right hive.

Monterey, Cal.

WM. A. SEDDING.

[While bees undoubtedly do recognize colors to some extent, we doubt very much whether they would be able to recognize one playing-card from another. They might distinguish a card that had all red on it from one all black; but as to whether they would be able to count the spots or to distinguish diamonds from hearts—well, we have our doubts. Bees are pretty smart creatures; but we can't believe they are able to distinguish cards.—Ed.]

How to Locate Quickly the End-spacing Staples

Perhaps some may be interested in my short cut for putting the end-spacing staples in place. I took the hard-wood block supplied with the frames, and cut one of the saw-kerfs 1½ inches long; then with a chip of section box, whittled thin, I stopped up all but 5-16 inch of the slit, leaving a hole for the staple. Then on the under side of the block I nailed, with ½-inch nails, a piece of bottom-bar, coming within ⅜ inch of the gauge hole.

I place a pile of end-bars on the table right in front of me, a saucer of staples, and a two-ounce hammer at my right; then I am ready for business. With the left hand I lay an end-bar in front of me, top to the right, bevel next to me, and lay the gauge on it with the stop piece, cut from a bottom-bar, in the notch. It fits loosely. The thumb and middle finger hold the end-bar steady, and the middle finger slides the stop into the notch and holds it there. With the right hand I pick up a staple, slip it into the gauge hole, hit it twice with the hammer, lift off the block, and throw the finished end-bar into a receptacle large enough to hold the whole season's supply.

It works like shelling peas. I soon wearied of handling both ends of a frame and maneuvering in an awkward corner; and, without thinking of the convenience of the bees, I saw that the staple would do better a little lower.

Our Homes

A. I. ROOT.

The Lord gave, and the Lord hath taken away. Blessed be the name of the Lord.—JOB 1:21.

Buy the truth, and sell it not; yea, wisdom and instruction and understanding.—PROV. 23:23.

He will not always chide; neither will he keep his anger for ever.—PSALM 103:9.

DEATH OF WILBUR WRIGHT, THE OLDER OF THE WRIGHT BROTHERS, OF DAYTON, OHIO.

For the past half-dozen years or so the whole wide world has been discussing and reading in regard to the Wright brothers (and their flying-machines) more than, perhaps, any other two people on the face of the earth. In every clime and in every language people have been eager to learn all about the two young men who have succeeded for the first time in human history in making a machine that would fly, and carry passengers, purely by mechanical means without the aid of a balloon or any thing of the sort. In the March 1st issue of GLEANINGS for 1904 I first made mention of the two men, Orville and Wilbur Wright. It was in the fall and winter of 1903 that they first succeeded in applying a gasoline-engine to a gliding machine they had been experimenting with. In the summer of 1904 I wrote the Wrights, asking permission to pay them a visit and witness some of their experiments. This permission was kindly granted; but they preferred that I should make no mention through our journal of what I might see until later on. I made many visits to the field just outside of Dayton, where they were experimenting during the summer of 1904; and finally, in our issue for Jan. 1, 1905, I was given permission to write up what I had witnessed, this being the first detailed account, if I am correct, given in any periodical in the world of the experiments and final success of the Wright brothers.

It was my privilege to be present when they made their first flight of a mile or more, and turned a circle and came down to the place of starting. My write-up of the event was so astonishing that many people thought it was a piece of fiction to advertise our journal; and even so good an authority as the *Scientific American* did not see fit to credit my account, although afterward they apologized for their want of faith at first, in my plain and simple story.

In times past it has been my good fortune to become more or less intimately acquainted with some of God's noble men and women; and I shall always regard it as one of the privileges of my life that I was permit-

ted to become intimately acquainted with these two great characters (and I might say *benefactors*) of the human race. Wilbur Wright, the elder, was a little peculiar. Usually he was rather quiet and taciturn; but when he got agoing he was quite a talker. There was a peculiar twinkle in his eye, and an expressive working of the muscles of his face when a new idea occurred to him or when he had something pleasant to tell. While the two men worked together in perfect harmony, they often had lively discussions. Sometimes, one would think these discussions were becoming pretty nearly heated ones; but all of a sudden they would both stop and pitch into the work, and perhaps in a little while demonstrate *who* was right and *who* was wrong.

As Wilbur was the older of the two, for a time he seemed to do rather more flying than his brother Orville. I once asked their assistant mechanic which one of the two, in his opinion, was the more expert. He said he could not tell—sometimes one and sometimes the other. They first made quite a good many experiments by simply flying ahead in a straight line. Then the machine at that stage of the invention had to be wheeled back to the starting-place by hand. One day I came on the ground just as they had succeeded in making it turn a curve so as to fly at right angles to its course. They were getting ready to make another attempt; but a thunder cloud loomed up in the west, and they were about to abandon the experiment for the time being. As every thing was all ready for another flight I took the liberty of suggesting that they would have plenty of time to get around and get the machine safely housed before the blow would come up. In thinking of it since, I have considered that it was rather presuming on my part for me, an outsider, to offer such advice. Finally Wilbur, who was, I think, rather more venturesome than his brother, said *he* was ready to try it, and accordingly they started off rather hurriedly. Wilbur turned the curve at the end of the field, as before, and turned still another curve, and came around to the starting-place, where we expected him to alight; but to our great surprise and astonishment he went right on, over our heads, and was heading for a lot of telephone wires, thorn trees, etc. The other brother, the mechanic, and myself, were greatly alarmed. It was so long ago that I can not exactly recall the details; but for a time it seemed to us he

turned the rudder with the apparent intention of going over the obstacles and out of the field; but when he had sailed high enough to clear every thing the engine stopped, and the machine gradually slid back on the air, and alighted as safely and as gently as a feather, in their own field. We all rushed up to where he stopped, to see what was the matter. As I was considerably older than the other two, I did not get there in time to see what started the "discussion," but Wilbur was evidently considerably stirred up, and he and his brother were disputing rather hotly as to whose fault it was that he could not get the engine *stopped* when he came back to the starting-place. I finally interrupted the discussion by putting my hand on Wilbur's shoulder and remarking, "Why, my good friend, can't you stop long enough to look pleasant, and thank God for having permitted you *just now* to make the first flight since the world began, turning corners, and coming around to the stopping-place?" He looked at first a little vexed at the interruption, but finally his countenance softened, and that peculiar—I might almost say bewitching—smile spread over his countenance as he put out his hand and said, so far as I can recall, "Why, Mr. Root, I guess you are right; and I *am* glad and thankful that I succeeded, even if I could not get my engine stopped when I wanted it to stop."

I do not remember now what it was that made the engine keep going after the switch was turned off. I only remember that he put the blame on Orville, and I suppose it came about on account of the excitement of the moment in consequence of the thunder cloud, that caused the accident.

Later, after they succeeded in getting the machine to make circles in the air as long as they wanted to stay up, I made them a visit and happened to be there at the same time as Mr. Chanute, a man who had made experiments with gliding machines before the Wright brothers ever took it up. I believe he is still living, and that he is also, perhaps, one of the best authorities in the world on aeronautics. They were discussing finances. Mr. Chanute thought a *million of dollars* would be needed to put the invention on a sound financial footing. I remember I noticed the peculiar twinkle on Wilbur's face as he said something as follows:

"Mr. Chanute, I have no ambition to be a millionaire. So far as I am concerned, I think a hundred thousand dollars would be all I should ever have use for in this world."

And this was characteristic of the man.* When he crossed the water and went over to England, France, and Germany with their invention, crowds followed them everywhere—not only common people but the nobility, crowned heads, kings, and queens came to recognize and do homage to the Wright brothers of Dayton, Ohio. Well, in some foreign lands, as you may know, where they do not know or *care* when Sunday comes, Wilbur always paid respect to God's holy sabbath day, and several times the nobility (and, I think, once or twice members of the royal family, great lords and ladies) wanted to see the Americans and the American flying-machine on Sunday. Now, here comes a true test of courage and of fearless manhood. I use the word "manhood" in the best sense of the word. Wilbur Wright said gently but firmly that they had been taught to "remember the sabbath day to keep it holy," and kindly asked to be excused, not only from making any flight, but from exhibiting the machine on the generally recognized Sunday of the world. He added that, as soon as the day was passed, he and his brother would gladly and cheerfully be at their service. This has been heralded world-wide; and, no matter what *opinions* people may have in regard to sabbath desecration, I think one and all, good and bad, reverence and respect the memory of Wilbur Wright for standing up and living up to his honest convictions. I do not mean that his brother Orville was any less conspicuous in this matter than Wilbur; but Wilbur, being the elder, generally took the responsibility of being spokesman.

During my first visit, and while the Wrights were making application for a patent on their invention, there were certain things I was asked to avoid mentioning in print. On my last visit, Wilbur invited me to go over and see their great factory. This was described on p. 602, Sept. 15, 1910. On starting out I asked if I might be permitted to describe in our journal what I saw. Wilbur replied with that

*In connection with the above I may mention that the Wright brothers were many times offered considerable sums of money if they would exhibit their machine at State fairs or great expositions; but their invariable reply has been, "Gentlemen, we are not in the show business." The years they labored in perfecting their invention were not for the purpose of making money. It was to bless humanity. I suppose they recognized full well that an advertisement saying the Wright brothers would be present with their flying-machine would draw a bigger crowd than the mention of any other two men on the face of the earth. But they have never been and are not now catering to the curiosity of the crowds that frequent great fairs, expositions, etc. They felt and now feel, as I have tried to express it, that God was calling them in another direction.

same expressive twinkle, "Mr. Root, tell any thing you like, providing you *tell the truth*, and only the truth." How many proprietors of our American establishments nowadays would instruct a reporter of a magazine (who is writing it up) to avoid exaggeration or overstatement in his relation of what he saw? I mentioned this incident in my talk to our Bradentown Sunday-school, in Florida, and urged the youngsters, who were listening to my account of the flying-machine, in the language of our last text, to "*buy the truth and sell it not.*"

One day we were all out in the field with the machine while there was a cool north-west wind. Wilbur was in his shirtsleeves while I, if I remember correctly, had on my fur cap and overcoat. I urged him to put on his coat lest he "catch cold." He looked up to me with one of those smiles I have mentioned, and said, "Mr. Root, I shall not catch cold out here in this breeze. That is not the way people catch cold as a rule. They 'catch cold,' as you express it, by keeping themselves shut up in hot and poorly ventilated rooms; and perhaps they may take cold by going out from such places warmed by artificial heat; but people who live outdoors, as God intended they should live, do not take cold, even if they get to feeling a little chilly."

I believe this was his rule of life. A great strong man, full of life, blood, and energy, has been cut off by typhoid fever; and at least a part of the responsibility rests on you and me. "God will not always chide."

It was my pleasure several times to share their noonday lunches put up by that good sister Katherine. May God bless and sustain her in this great affliction. Well, their food was always plain, wholesome, and in keeping with their ideas about the importance of open air, etc. *Why* should he have been permitted to die when the world needs *such* men so much? "The Lord gave, and the Lord hath taken away."

I suppose the whole world knows that, while I write on this 31st day of May, 1912, Wilbur Wright is no more. He died on the early morning of Decoration day; but before the day was fairly closed, messages of condolence and regret came from those same foreign nations where they censured him but a few months ago, because he so firmly, as they put it, refused to fly on Sunday. May God be praised that such a man as Wilbur Wright has lived for 46 years to bless the world. His sad, sudden, and untimely death came from typhoid fever; and almost at the very time when the sad news reached us I had in my hand a little bulletin sent out by the Department of Agricul-

ture a few months ago, entitled, "How to Prevent Typhoid Fever."* As nearly as I can make out at this early date, he caught the fever while absent from his own beautiful sanitary home in Dayton.

In a recent issue I spoke of the way the Titanic disaster had taught us a lesson that the world could not be taught, perhaps, *without* such a loss of life. It has long been recognized, I believe, that typhoid fever is the result of ignoring well-known and sanitary laws. Is it possible that the loss of this good man, of so much value to the world at just this moment, is a part of God's plan to teach us not only to banish the *flies* that carry contagion, but to banish the filth that is feeding the flies even around farmers' homes, enabling them to increase and multiply? This bulletin I have been speaking of, says typhoid fever is more to be dreaded than smallpox; and may God help us to learn from this lesson what he is striving to teach us. When these government bulletins are furnished free, and when our farm papers, daily papers, and magazines are exhorting us, and we *still* sit down with folded hands, shall we not consider out text, "He will not always chide"?

*Another recent bulletin is on my desk entitled, "House Flies," and it has considerable to say in regard to the "typhoid fly," and the way in which the common house fly carries the typhoid germs. In fact, Prof. L. O. Howard says:

The insect we now call the "house fly" should in the future be termed the "typhoid fly," in order to call direct attention to the danger of allowing it to continue to breed unchecked.

"THE TITANIC DISASTER."—HAD GOD ANY THING TO DO WITH IT?

A. I. Root:—I have just reread your last *Homes*, and want to thank you for your brave strong words. Surely some of your conclusions regarding the Titanic disaster are worthy of world-wide notice. Some Bible-reading people have said, "God had nothing to do with that calamity." Strange to me is the fact that a great ship going swiftly *west* should meet an iceberg going south at just the right moment, at the exact danger-point, with a smooth sea, near the midnight hour, where the water is two miles deep. Could men or angels or even *demons* be more skillful? The mystery seems to be unraveled when we read the various bits of testimony you have gathered. It was a terrible lesson to the world—*yes*, a *costly* lesson; but we may conclude that God does not undertake wealth as of much importance when he undertakes to teach the nations of earth a lesson.

I want to bid you Godspeed in your efforts as a writer. I think I can understand your interest in the *important* things of life. I have felt a tendency that way for some time; and a few lines of verse, written years ago for the *Day Star*, have come to mind with seemingly greater force and deeper meaning as the years slip by faster and faster; and many things seem now of less value than formerly.

OUR GREATEST NEED.

We want the power to choose the proper word—
Power to make our whispers heard:
Indeed, we covet, we desire
A pen of flame like torch of fire
To carry light and blaze and heat
To every soul we chance to meet—
Power to shield our youth from sin;
Power a *million* souls to win
To Christ, the Savior, Prince of Peace,
Whose reign begins when wars shall cease,

For power these principles to teach
To every soul we chance to reach.
Dear friends, when next in prayer you plead,
Remember this—our greatest need.

I was pleased to note what you have to say about voting for men in public place who wish to guide the great ship of state. Surely 'tis time to draw the line. See the Roosevelt edition of *Clean Politics*; and editorials in the *Outlook*. For myself I deem T. R. one of the most dangerous men before our

people. His military sentiments and cowboy cruelty will leave a great stain on the churches of the world that will not soon be removed.

Well, cry aloud and spare not. The old prophets are not any more popular than they used to be; but I am glad to believe they have *still* a message, and a goodly number are willing to hear and heed it, and some of the prophets will bring forth their *best* fruit in old age.

May the Holy Spirit lead you ever.

Boulder, Colo., May 23.

CHUFAS, OR EARTH ALMONDS.

Perhaps some of the friends will wonder if my enthusiasm has all evaporated in regard to the above ground nut. Not at all; but my enthusiasm for 100 bushels an acre has received a severe shock. Down in Florida, I had a yield in spots that might have been thirty or forty bushels to the acre. Here in Medina (see picture, page 598, Oct. 1, 1911) the fine stand I had was frozen out during the past severe winter. The reason I did not dig them before I went to Florida was on account of the prevailing wet weather. We dug a few; but the task of picking and washing them out of the mud was, I decided, more than they were worth, even if they did bring \$4.50 a bushel. And by the way, there is one drawback in growing chufas; and that is the difficulty of harvesting them. Suppose you had a lot of white beans scattered all through the ground like potatoes. How could you harvest them? how much would it cost? In the Florida sand it is quite a little easier; but even then they have to be hand-picked, so far as I can see, in order to have a clean crop.

Well, I am just as fond of roasted chufas as I ever was. There is no nut to compare them with for myself. We had a good many that were self-sown, or "volunteered," as some would call it, in Florida; but the moles or mice, or something else, ate up a great part of them before we got around. Now, in view of the above, imagine my surprise to see the following in Hastings' (Atlanta, Ga.) seed catalog:

The South buys more than a hundred million dollars' worth of meat every year. How many of your dollars help swell that enormous meat-bill? With chufas and peanuts you can grow meat just as cheaply as the Western farmer. Chufas can be planted as late as June 15, and make anywhere from 200 to 1000 bushels per acre, maturing in the fall, and can be left in the ground until you are ready to turn the hogs in on them. Highly recommended by the experiment stations of Alabama, Florida, Louisiana, and Arkansas. Exceptionally plump, sound, re-cleaned seed. Pound, 35 cents postpaid; peck, \$1.25; bushel (44 lbs.) \$4.50.

What do you think of the above—1000 bushels per acre? If they were all sold at \$4.50 they would bring \$4500. Surely that amount would pay for fertilizer *ad libitum*,

the best kind of underdrained and irrigated soil, and plenty of labor. Will the readers of GLEANINGS please tell me if they ever saw, not 1000 bushels, but even 100 bushels grown on one acre? The above advertisement is clipped from the *Southern Rural*. They recommend chufas for producing pork cheaply. Of course the hogs would do the "harvesting," so all the farmer would have to do would be to raise the crop. I did not know but they might stand freezing like artichokes, so they could be dug in the spring. I know they sometimes winter over in the ground here in the North, because I have seen them coming up the following spring where they were grown the year before. I am going to write Hastings and ask if the printers did not put in one cipher too much in the above estimate.

SWEET CLOVER FOR INOCULATING SOIL WHERE
EITHER RED CLOVER OR ALFALFA IS TO

BE GROWN.

Mr. Root:—I have just read about sweet clover in your May 15th issue. Nothing was said concerning inoculation of the soil with bacteria suitable to sweet clover. Several years ago I sowed red-clover seed in the corn in July, and got a fine stand. A strange plant (strange to me then) showed itself quite plentifully among the clover plants. This plant proved to be alfalfa, and came because in some way the dealer from whom I purchased the seed had gotten the two kinds of seed badly mixed. The alfalfa grew and thrived best near the road. The further away from the road, the less alfalfa. The road alongside the field has grown wonderful crops of sweet clover for a very long time. A young neighbor, who has lately taken a short agricultural course at Champaign, Ill., told me the reason the alfalfa grew best near the road is because the dust from the road blew into the field and inoculated the soil best near the road; and the further away from the road, the less inoculation. The soil bacteria for alfalfa and sweet clover is one and the same.

Peru, Ill., May 21.

E. H. WHITAKER.

Friend W., you have furnished us a highly important fact. Our Ohio experiment station at Wooster has for some time recommended getting soils from the roadsides where sweet clover grows, to inoculate fields for alfalfa. I have just been looking at about the finest stand of sweet clover I ever saw. It is on a piece of ground near our largest warehouse, where hard yellow clay was spread, that was taken out in excavating a basement. This hard yellow clay would ordinarily not grow any thing at all,

unless, indeed, a heavy dressing of stable manure was worked into it. But without any dressing whatever it is just covered with about the rankest growth of sweet clover I ever saw. The clover is now about three feet high (May 30). We propose to cut it with a scythe for our horses and cattle. I thought at first some member of our firm had directed the sowing of sweet-clover seed; but they all say they did nothing of the kind. Sweet clover, however, has been growing for years along the bank of a railway cut, a few yards away. The wind probably scattered the seed more or less over this freshly moved hard clay soil. The seed must have come up and made some growth last fall, but it was not noticed. Now, this hard, impervious clay was just the place where the sweet clover could clinch its roots preparatory to pushing straight down that heavy thick tap root. See page 323, May 15. Just here I am reminded of something funny that happened several years ago.

JADOO FIBER FOR GROWING POTTED STRAWBERRY PLANTS; WHY WAS IT GIVEN UP?

Many of our readers will remember that several years ago I was enthusiastic about growing strawberries in little pots filled with jadoo fiber. This fiber is so light that it can be readily sent by mail, with sufficient moisture to keep the plants in excellent condition in transit. You may recall that we did quite a little business one fall in mailing these potted plants in jadoo.

I felt sure it was going to be a great invention. What was the trouble? It was this: We planted out several hundred in our own fields, and they started off so finely I expected a great crop from them. Imagine my surprise and chagrin, however, to find in the spring every potted plant set in jadoo out on top of the ground, and winter-killed, while those potted in clay or common garden soil stood the winter all right. The jadoo is so soft and yielding that the roots could get no hold on the soil, and every plant was thrown out by the frost. Had the jadoo been all washed off from the plant when first put in the open ground, so the roots could get a new and firm hold in ordinary soil, they would, perhaps, have held their own. Now, this illustrates exactly what happens when sweet clover is sown in good mellow fertile soil—that is, soil good for other crops. But when the seeds are dropped on the hard roadside or in a brickyard or on a railroad bank of hard unfertile clay, so it can get hold and push down that tap root, then it winters all right. The hardest, most unpromising, and impervious soil seems to have stood it the best.

Just a word more about jadoo fiber. Several have inquired lately why it is not now

manufactured and in the market. I believe that florists ceased using it first, because it was too expensive; and, second, because the plants seem to need, sooner or later, a stronger and more compact soil to grow in. I still think, however, that where plants are to be sent by mail, and have them reach the purchaser in good order, it is the best thing ever invented for the purpose.

POKEWEED FOR GREENS; GOLDEN BANTAM SWEET CORN.

Mr. Root:—I have just read of your latest new discovery, i. e., that pokeweed makes good greens, and believe you should, if possible, add a word of warning in your next issue. There is considerable poison in the root of poke, and in gathering it one should be careful to break the young shoot an inch or so above the root to avoid the possibility of getting any of the toxic properties. Some have been poisoned by carelessness in this matter. Poke was common in my former home in western Ohio, and used for greens by many farmers' families, but was not generally liked when cooked alone, being too soft and slippery. But when used with dandelions, dock, chard, liveforever, turnip-tops, etc., it was quite popular. Please tell us more definitely how to cook it as was done by your Florida neighbor. This may be the new discovery.

In my old home in Ohio, what was called poke was a large weed, one to two inches in diameter at the base, three to five feet high, and with berries in clusters like currants in late fall, and into the winter if not eaten by birds. This was eaten as greens only when the shoots were young, never when more than about eight inches high. Here a very different plant is poke, one which grows in boggy places in company with skunk cabbage, only a foot or two high, leafy like cos lettuce, and claimed to be very poisonous. What is called poke in Ohio (and Florida, I presume) is here called "skoke." The berries are often called pigeon berries. Now, if your statement on page 288, that poke, a supposed poisonous plant, is delicious when served as asparagus induces any one to eat this Log plant it may result in serious sickness or even death, and, if possible, a correction should be made in your May 15th issue.

It is quite odd how plants and things generally are called by different names in different sections of our country. What is called dog-fennel in Ohio is here called Mayweed; lambquarter is called pigweed; hickory trees or nuts are called walnuts; shafts are thills; singletree is whiffletree; doubletree is evenier; but about the most peculiar provincialism here is calling a wagon a team.

Is it possible you have not learned that Golden Bantam sweet corn is much the hardiest, and may safely be planted while the ground is far too cold and wet for any of the white sweet corns? If so, you surely do not read your seed catalogs carefully. I am sending herewith leaves from some of the 1912 catalogs, on which I have marked the statements about the hardness of this variety.

Packer, Conn.

E. P. ROBINSON.

Thanks for corrections, friend R. The pokeweeds that we gathered in Florida were simply snapped off like asparagus, usually several inches above the surface of the ground. It is cooked exactly like dandelion greens. I supposed, without making inquiry, that they were simply boiled in water.*

You are probably correct in regard to the Bantam sweet corn, and I take pleasure in submitting to our readers the following extract from Burpee's catalog. I be-

*In consulting our dictionaries and encyclopedias of recent date I find pokeweed, but no mention of pokeweed, although it is true here in Ohio we have always been in the habit of calling it skokeweed.

lieve most seed-dealers now usually carry the Bantam in stock.

This corn is becoming each year more firmly fixed in popular favor because of its *extremely early character, vigorous growth, and surpassingly delicious flavor*. We have had hundreds of most enthusiastic letters from customers, giving it the highest praise as the *finest extra-early sweet corn* they have ever grown. Although the dry grain is entirely free from any flinty glaze, it is exceptionally hard and firm, hence can be planted *earlier* than any other *true sweet corn*. The stalks are dwarf and sturdy in habit, growing to a height of four feet. They bear two and three fool ears, which are set well above the ground. The ears, five to seven inches in length, have eight rows of broad yellow grains, extending to the extreme rounded tip.

We first grew this Golden Bantam in northern Michigan, close by the "cabin in the woods." Since then we have grown it every season, and recommended it to the rest of the Roots and our neighbors; and we all agree with what is said in the above extract. By the way, I think we owe a vote of thanks to that enterprising seedsman, W. Atlee Burpee, not only for the Bantam corn, but for the many other good things he has given us.

POKEWEED "GREENS;" STILL MORE ABOUT IT.

My father tells me that fifty or sixty years ago he remembers eating pokeroot cooked as greens, but is under the impression that, if gathered in certain seasons, it is unfit for food.

My wife tells me that when a girl her mother cooked pokeroot. The earliest shoots alone were used, the shoots being peeled and parboiled to extract the poison, and afterward cooked and eaten as asparagus.

Mrs. Hamlin thinks that, if left too long before gathering, poke is poisonous. This is as explained to her by her father. I have not felt like having my family use the plant, not knowing enough about it, and I should be pleased if GLEANINGS would tell us how it is cooked for the table, when it is best to gather it, etc.

Pittston, Pa., May 8. P. M. C. HAMLIN.

Later.—I just now find the following in the *Rural New-Yorker*:

FALSE HELLEBORE.

This has very bright green stemless plaited leaves, coming up in thick tufts in spring. It is very distinct, but is occasionally gathered with marsh marigold, and boiled for spring greens, with fatal results. The plant, botanically, *Veratrum viride*, is also called Indian poke, wolfsbane, devil's bite, and bear corn. It must be remembered that vegetable poisons are very variable in character, and individuals also differ in degree of immunity. The deadly upas of Java may be handled with impunity by a person who would be blistered by an innocent little Himalayan primrose.

From the above I gather, as I before intimated, that there *is* some plant (may be Indian poke) resembling pokeweed; and this plant is probably responsible for the poison.

TOBACCO-GROWING IN OHIO; SHALL WE ENCOURAGE OUR BOYS TO ENGAGE IN THE INDUSTRY?

As a rule, I feel happy to get a new farmers' bulletin—especially one that emanates from our Ohio Experiment Station; but just now I am greatly pained to receive a nicely written and printed pamphlet, purporting to come from our Ohio Experiment Station at Wooster, with the heading, "To-

bacco-growing in Ohio." I have carefully scanned each of its nearly hundred pages to see if I could find a single sentence even remotely touching on the benefits of tobacco-growing to the people of the State of Ohio, especially to our boys and girls. This bulletin holds out no incentive to the industry except the *money* there is in it; and, if I am correct, the summing-up does not show that the profit is any more than that from growing corn, wheat, and potatoes, if as much. I happen to know (may God be praised) that the experiments with the tobacco plant are not conducted on the great farms at Wooster. When the Board of Management wished to have tobacco included in a list of farm products, there were at least two farm professors, and I do not know how many more, who objected; therefore the tobacco industry is conducted at some of the sub-stations in different parts of the State. I could not discover from the bulletin just where. It is a grand and glorious thing, this matter of introducing, even in our public schools, lessons in agriculture, and teaching our boys and girls to be expert in growing good and wholesome food for a hungry world; but (God help me while I say it, to have nothing but love and charity in my heart) who is there that *dares* to stand before our people in public or in print, urging that progress in growing tobacco will be a benefit to the coming generation of boys and girls? Of course, tobacco culture would include as a side issue the manufacture and sale of cigarettes. Let me give you a clipping right here from that grand little monthly, the *Philadelphia Farm Journal*:

STAMP IT OUT!

Judge Burke, of Chicago, has stated, "Our laws and times would not tolerate for one single moment the cigarette evil if the desolation which it works could be fully realized."

The *New York Journal* recently printed the following facts:

It is estimated that from 1200 to 1500 boys begin smoking every day.

Bad habits are the starting-point of criminal careers. Crime is keeping pace with the cigarette habit. Ninety per cent of youthful offenders are cigarette-smokers.

Students' mental and physical efficiency is lowered by smoking.

Tuberculosis fatalities are greatest among cigarette-smokers.

The cigarette is considered a key to the insane asylum.

Most school dullards and truants are cigarette-smokers.

The cigarette torch imperils life and property everywhere.

Eleven States have prohibited the manufacture and sale of cigarettes. Prohibitory laws are upheld by the United States Supreme Court.

All right-thinking people demand the extermination of this pest of society. Will you, boys, do *your* part in helping to stamp out the evil?

And, by the way, may the Lord be praised that our agricultural periodicals, almost if not quite without exception, are holding up a high standard of morals for these same "coming boys and girls."

POULTRY DEPARTMENT

A. I. Root

"NATURAL-HEN INCUBATORS," ETC.

Below are two advertisements that I clipped from poultry journals, and which I have decided to insert here without charge.

MARVELOUS! INCUBATOR WITHOUT LAMPS; USES NO OIL—BIG HATCHES.

A 200-egg size *Natural Hen Incubator* for \$3. Most successful for 10 years. Patented in U. S. and foreign countries. Hen herself controls heating, turns and airs eggs—does everything. No expense of heating. *Agents wanted.* Write for catalog to-day. Big money.

Natural Hen Incubator Co., 1349 Constance St., Dept. 4, Los Angeles, Ca.

200-EGG HATCHER, \$3.00.

Why pay \$20 or \$25 for a 200-egg hatcher with only a five-year guarantee, when you can now get one for \$3 guaranteed to hatch every hatchable egg and last for 50 years! This wonderful invention is called the PARADISE HATCHERY, which is pronounced by all to be the greatest hatcher for producing strong livable chicks ever invented. You'll say the same after you see and use one, and you'll wonder how you ever got along without it. Do you want to eliminate all your hatching troubles, and experience a successful hatching season? My free circular contains information that will put you right. Write at once.

Elmer S. West, box 30, Ewing, Ky.

Please notice that each one of them offers a 200-egg incubator at \$3.00. Well, on investigation you will find that both parties have no incubator at all to sell, and never did have. What they have to sell is a single sheet of paper, and you are to pay \$1.00 for this sheet of paper when you ought to have for the money a good-sized book, at least fairly well illustrated, of their invention. The first one of the two, hailing now from California, has been running this business for perhaps a dozen years past; and although I have shown the parties up through GLEANINGS every year or so, yet it seems they still succeed in raking in sufficient dollars from the innocent and unsuspecting to keep on advertising. I have remonstrated with the poultry journals; but many of them seem to think that, as long as they get *pay* from the advertisers, nothing more is required. What these fellows have to sell is a description of an apparatus to hold a dozen sitting hens or a smaller number. A hen's nest, with a little doorway attached to keep the hen from straying away, or from being annoyed, is as old as the hills; and a group of these nests, with their little dooryard of poultry-netting or lathwork, is almost as old. It has been described and pictured in our farm journals time and again in years past. Very likely the venders have some sort of patent right on some detail of the construction of their apparatus. In years gone by, I have sent a dollar for it every little while to see whether any improvement was being made—that is, for the California machine. I

admit they have some satisfied customers, because there are many people who have never seen the arrangement and do not know that it has been for years before the public. The latter one of the two advertisements, coming from Louisville, Ky., is a copy, as I take it, of the California arrangement, notwithstanding he says in his advertisement:

HAVE NOT BORROWED.

Don't imagine for a moment that my invention is like other inventions or "poultry secrets" that are now being advertised and exploited in poultry journals throughout the country; for it is *entirely* original, and unlike any hatching device thus far produced; and I control the sole right of this wonderful invention; and all persons infringing on my rights will be vigorously prosecuted.

Once more, the second man says:

SIMPLICITY AND PRACTICABILITY.

The Paradise hatcher is so simple in its construction that any person who can drive a nail and saw a plank can, by following our simple written form of instructions and descriptions, together with the plain illustrations, easily construct a hatchery in a few minutes' time, at a very small cost.

Now, notwithstanding he says any person who can "drive a nail or saw a plank" can make the thing "in a few minutes," I do not believe that the average carpenter can make one in a whole day—that is, if he has to saw out the stuff and nail it together. In fact, I am not sure he could make one at all with the meager diagrams furnished, without the assistance of some poultryman; for although I have spent considerable time in trying to cipher it out, I am not sure I could tell how to make one at all from the directions.

The directions that were sent me for my dollar were evidently *printed* wrong. The figures are marked out, and different ones put in with pen and ink. Once more, you will see by the advertisement that he sells the 200-egg hatcher for \$3.00. Now, the bill for lumber and material *alone*, according to his own figuring in plain printed instructions, is \$4.00 for a 200-egg 12-hen hatcher, to say nothing about nailing up and painting. Once more, both parties make a big point of no expense for lamp, oil, etc. But how about the expense of a dozen sitting hens, keeping them from throwing up their jobs, watching the eggs when they happen to break them, keeping out vermin, etc.? If this sort of advertising is not using the mails for fraudulent purposes, then I am mistaken.

Just one thing more about the natural-hen incubator. Even after you have read their "spread-eagle" advertisements you

may not be tempted to send a dollar right off, but wait a while. In about ten days you will get something additional, saying that, for some special reason, they have concluded to cut down the price to 75 cts. But if you still delay, a little later comes an offer for the small sum of 50 cents for a "full individual right," and a lot of valuable recipes thrown in; and I think, although I have not now the documents on hand, that still later they come down to 25 cents. And this is a fair illustration of a lot of schemes to get your money by some hook or crook. Whenever any advertiser, after a few days, begins to cut down his prices, look out for him. See what I have said about the "memory school" on page 23, advertising pages, May 1.

Since dictating the above, the *American Poultry Journal* for June has come to hand, and in it as good an authority as Prince T. Woods, M. D., describes and pictures an incubator which is substantially the same thing as mentioned above. Below is the opening paragraph:

Would you like to build an open-air incubator, one that can be run out of doors from the middle of March until late in the fall, one that costs only about \$1.50 per 150-egg capacity, labor included, one that hatches by the natural method, and will hatch every hatchable egg that a good sitter can hatch? If so, build and try a Wozelma open-air natural incubator, ten-hen capacity.

You can easily build one from waste lumber, a little wire netting and roofing fabric, by following dimensions here given, and using the illustrations from photographs for a guide. Ours holds 150 eggs, fifteen under each hen, ten compartments, a sitting hen in each compartment. It costs about 75 cents for material and less than two hours' labor.

The description of how to make it occupies something more than a full page, including four excellent photos of the sitting-hen incubator in actual use. Please notice what I have said about the sitting hen giving larger fertility than the average incubator, or perhaps any incubator. There is no question that these things are a success if properly made and handled. But think of charging a dollar for the crude directions, few or no illustrations, on a single sheet of paper, when the whole thing is given by an able writer and an expert poultry-keeper in one of our poultry journals!

Still later.—In the *Poultry Tribune* for June our good friend Mrs. Mattie Webster writes as follows:

I think the most convenient and greatest labor-saving device is the "hatcher," where each hen may have her individual run where she may exercise, and there have placed food, water, and grit. We have one of thirteen nests and runs, and you may be sure the first thirteen broody hens are always set in this hatcher.

Still further, I just now discover that in the frontispiece in that valuable little book, "Poultry Secrets," is a collection of nests for sitting hens with a latticed dooryard for each hen.

BLOOD-STREAKED EGGS, ETC.

I should very much appreciate having you request your poultry department to advise me of a remedy as well as suggest the cause of the following affliction which seems to affect a few of my hens. Occasionally a hen will appear to be suffering from an internal hemorrhage which lasts for two or three weeks, and which is evidenced in the form of bloody piles. Perhaps it is due to the food, or some germ of disease.

Chicago, Ill., May 30.

C. F. CHILDS.

My good friend, I regret that I am not able to suggest a remedy; but very likely some one who reads GLEANINGS may be able to give us help. I had one hen in Florida whose eggs were streaked with blood more or less. On examination I found about the same conditions you mention. I put her off by herself, and gave her a diet principally of bread and milk, and she recovered. Whether the treatment had any thing to do with the recovery or not I am unable to tell. Where a large number of fowls are kept I believe it is often the case that there will be occasionally an egg that has marks of blood on it as I have described.

INDIAN RUNNER DUCKS.

The May number of the *Pacific Poultryman*, Seattle, Wash., is a "duck number," and principally devoted to the Indian Runner duck. There is a large number of contributions from those having tried the Indian Runners, and every one gives a favorable report in regard to them. I am not surprised to see a special number of this poultry magazine devoted to the Runner ducks; and I shall not be much surprised to see a journal started very soon, all devoted to the raising of Runner ducks. The objection has been raised that the Runners are large eaters. Here is what one of the writers in the above journal says in regard to it; and the statement accords most emphatically with my own experience.

They are large eaters; yes, but they make every bite they eat count to good advantage. Besides, they eat cheap food, for one half their feed may be green feed.

Give them plenty of green food that they like, such as lettuce, mustard, dandelion, or even good fresh grass, and you will save half the grain needed, or more.

THE SITTING HEN AHEAD OF ANY INCUBATOR FOR STARTING FERTILITY.

I make two clippings from the *Poultryman* in regard to this matter.

I am convinced that no incubator will start all the fertile duck eggs.

The hen is the best incubator, and, if possible, eggs should be given to hens for a week or ten days before placing them in the incubator.

Will not our experiment stations test this matter thoroughly with our best incubators? It is certainly an important matter to be settled, and the experiment stations of our different States, being unbiased, are the proper ones to settle it.

NO. 13

Editorial

PLEASE send in postal-card reports, of one or two sentences, telling what the prospects for honey are this season in order that we may make up a general report for the entire country.

OUR cover picture for this special issue represents an extracting apiary toward the close of the honey-flow, with the full supers stacked up four and five high. Talk about a refreshing sight for tired eyes! Is there any sight that is grander, to a beekeeper, than a nicely kept apiary of "sky-scraper hives"? This picture was made from one of Mr. Hutchinson's old negatives. We have now used ten of them in all, as cover pictures for the following numbers—December 15, January 15, February 1, February 15, March 1, March 15, April 15, May 15, June 1, and July 1.

PROSPECTS FOR THE HONEY CROP THIS SEASON.

If it had not been for the terrible losses of the bees over the country last winter and spring, indications are that this would have been one of the best honey years ever known. As it is, in many parts of the country, especially the clover districts of the North, bees are booming. Tons of nectar will go to waste this year because there are not enough bees to gather it. In the vicinity of Medina, at least, we are having one of the old-fashioned heavy yields from clover; and at this date, June 25, we are having to extract in our queen-rearing apiaries—something that we are almost never obliged to do. We have five outyards besides the home yard. All hands are busy giving room and extracting. With white and alsike clover in their prime, and basswood just beginning to bloom, and with a greater abundance of sweet clover than we have ever known, the prospect certainly looks very bright for honey at Medina. We have learned not to be too hopeful, however, for "there is many a slip 'twixt cup and lip."

FIVE-BANDED OR GOLDEN-TO-THE-TIP YELLOW BEES; DO SUCH BEES ACTUALLY EXIST?

THERE has been considerable correspondence between the breeders of extra-yellow bees and this office as to what constitutes five-banded stock. Some breeders, evidently, have been counting the dark segments as well as the yellow ones to make up the five bands. Others say there is no such thing as an all-five-banded colony, and that they have never advertised such bees. Others say that it is impossible to breed *bees* that will show yellow to the tip—that is, bees having abdomens entirely yellow without any black showing at all. We are inclined to believe that this statement is entirely true. It is an easy matter, comparatively, to produce *queens* which will have abdomens that are entirely yellow, and it is comparatively easy to produce *queens* that will produce *drones* that are yellow all over; but we have yet to see any queen that will produce yellow-all-over *bees* to the extent of ninety to ninety-five or even one hundred per cent of the entire bees of the colony. It is our opinion that, where a breeder advertises five-banded bees, he should furnish exactly that kind of stock—that is to say, queens that will produce five-banded to the extent of ninety per cent of the whole colony. Queens that will produce bees ten per cent five-banded, fifty per cent four-banded, and forty per cent three-banded, do not come up to the standard by a long way, if we are any judge. We do not think there is one of our queen-breeders who has a desire to misrepresent in his advertising in the least. A part of this confusion in advertising has come about through a misunderstanding as to what constitutes yellow-to-the-tip bees or five-banded bees. An advertiser can advertise truthfully yellow-all-over queens or queens that will produce yellow-all-over *drones*. The public should understand, however, that not the color of the *drones* nor the color of the queen constitutes the color of the bees themselves. A

queen may be yellow all over, and produce perfectly black bees. Conversely, a queen that is almost black may produce bees that are very yellow. We have seen this time and time again. The color of the queen is no criterion of what the color of the bees will be, although as a rule an extra-yellow queen, if she mates with an extra-yellow drone, will produce her kind. But an extra-yellow queen, if she mates with a dark drone, will produce all colors of bees ranging from dark to very light yellow; or she may produce miserable-looking hybrids because the bees take after their father. As is well known, all offspring, whether insects or animals, will resemble the father or look like the mother, and sometimes both.

Again, we find that there is some confusion as to what the term "golden" means. One breeder takes the view that it implies "yellow-to-the-tip." Others seem to give it a more flexible scope, meaning four and five-banded bees, or bees that are much more yellow than ordinary three-banded stock. When we refer to a "golden sunset" we may mean a beautiful ball of fire fringed with red and white with a predominance of golden yellow. In the same way we would say that "golden Italians" are nothing more than extra-yellow Italians—bright pretty bees with three, four, and five bands all in the same hive. In other words, a colony of goldens should show much more yellow than the ordinary stock.

THE NEW COLORADO COMB-HONEY GRADING RULES.

ALONG last December the Colorado Beekeepers' Association, one of the most influential organizations in the United States, adopted a new set of grading rules that in many respects are a decided advance over any thing that has been proposed heretofore. Not only the rules but the general suggestions on grading are worthy of careful reading by our Eastern beekeepers as well as those of the West. Here are the rules, together with the suggestions for grading:

NEW HONEY GRADING RULES ADOPTED BY THE COLORADO STATE BEEKEEPERS' ASSOCIATION, DECEMBER 13, 1911.

FANCY WHITE.—Sections to be well filled, comb firmly attached on all sides and evenly capped, except the outside row next to the wood. Honey, combs, and cappings white, and not projecting beyond wood; wood to be well cleaned; no section in this grade to weigh less than 13½ ounces.

No. 1.—Sections to be well filled, combs firmly attached on all sides and evenly capped, except the outside row next to the wood; honey white or very light amber; comb and cappings from white to slightly off color; comb not projecting beyond the wood; wood to be well cleaned; no section in this grade to weigh less than 13½ ounces.

CHOICE.—Sections to be well filled, combs firmly attached, not projecting beyond the wood, and entirely capped, except the outside row next to the wood; honey, comb, and cappings from white to am-

ber, but not dark. Wood to be well cleaned; no section in this grade to weigh less than twelve ounces.

No. 2.—This grade is composed of sections that are entirely capped, except row next to the wood, weighing from ten to twelve ounces; also of such sections that weigh 12 ounces or more and have not more than 50 uncapped cells all together, which must be filled; combs and cappings from white to amber in color but not dark; wood to be well cleaned.

EXTRACTED HONEY.—Must be thoroughly ripened, weigh 12 pounds per gallon. It must be well strained, and packed in new cans. It is classed as white, light amber, and amber.

STRAINED HONEY.—This is honey obtained from combs by all other means except the centrifugal extractors, and is classed as white, light amber, amber, and dark; it must be thoroughly ripened, and well strained. It may be put up in cans that previously have contained honey.

GRADING INSTRUCTIONS.—The aim of establishing grading rules is to secure uniformity in the methods of packing and grading, and thereby make it possible to put on the market a product of such excellence that careful buyers will pay top prices for it.

A few brief directions are deemed necessary to the parties doing the actual work of preparing, grading, and packing.

In removing filled supers the smoker must be kept well filled so no ashes will spot the cappings. Robber bees must be kept from them; and when piling supers up in the honey-house, one or several sheets of newspaper should be used between supers, to catch any possible drip and keep out dust and ants.

The shipping case adopted as the standard by the Colorado State Beekeepers' Association is the double-tier case with glass front, holding twenty-four sections, 4¼ x 1¼ x 1½ inches each. Use slim cement coated flat-head nails one inch long for nailing cases, put the best-looking side of grooved front strips to the outside, and select the best and smoothest finished boards for covers. If bottoms or cover boards should project, they must be planed off. This is necessary for proper loading. A sheet of plain paper goes into the bottom of the case, forming a tray; on top of this belongs a sheet of corrugated cardboard, corrugations up. On top of the lower tier of sections goes another paper tray and cardboard. Generally a sheet of corrugated cardboard is also furnished to lay on the top tier of sections. If this is not the case, and plain paper is used, it must not be permitted to stick out of the case.

The mark of the grade of honey must be put into both handholes of each case, as follows:

Fancy white must be marked XX in handholes.

Number one must be marked X in handholes.

Choice must be marked in handholes.

Number two must be marked II in handholes.

Sections must be well scraped. This means that all propolis (bee-glue) and beeswax must be removed from the edges and outside of all sections of honey. Some use a short and very sharp butcher-knife with broken point; others prefer a smaller knife with a square edge, kept square by the frequent use of a file. Sections that are badly mildewed must be put into the cull honey.

The cleaning and grading of honey must be done in a well-lighted place, but not in the direct rays of the sunlight. A well-ventilated and screened room with one or several large north windows is the ideal. No grading should be done by artificial light, because neither artificial light nor strong sunlight will enable a person to grade comb honey properly, owing to its transparency. A large bench or table is needed to give plenty of room for the work and the placing of shipping cases to pack the various grades in. Except for the fancy white it is necessary to have several cases for each grade on the bench so that honey of the same shade and finish will be cased together. Even in the No. 2 grade the packing of various shades of color in one case is bad work.

To avoid errors in casing, each grade should always have the same space on the bench, and cases should be marked with grade before covers are nailed on.

If possible one person only, with a good eye for color, should be entrusted with the work of grading the crop. The other work may be done by any number of persons. This plan secures uniformity of grading, and places the responsibility for this most important work on one person. The grader should be provided with a copy of the grading rules and

specimen sections, two or three of each grade, the poorest that are to go into each grade, have these specimens properly marked, and kept before the grader at all times, with instructions not to put any thing into a grade poorer than the specimens; and if in doubt about a section, to put it into the next lower grade.

A sensitive spring scales, with large dial, plainly indicating $\frac{1}{2}$ ounces, is needed for weighing doubtful sections. A scales especially adapted for the work can be bought for \$1.50. After using the scales for a short time most graders will find that but a small part of the crop needs to be weighed, as they soon get very efficient in judging weights.

The front sections of honey in a case must be alike in color and finish, and a true representation of the contents.

COMB HONEY NOT PERMITTED IN SHIPPING GRADES.

Honey packed in second-hand cases.

Honey in badly stained sections.

Honey showing signs of granulation.

Leaking, injured, or patched-up sections.

Sections containing honeydew.

Sections with more than 50 uncapped cells, or a less number of empty cells.

Sections weighing less than the required weight.

Such honey may be sold around home or rendered.

Don't put off. Case comb honey as soon as taken from the hives, and market while weather is warm. The early market is usually the best.

Don't haul without springs, and don't allow cases to get soiled or dusty.

Don't ship comb honey in less than car lots unless packed in carrier crates holding 8 cases each, with straw in bottom.

Don't ship by express, except very short distances. Freight is cheaper and just as safe.

Notice.—As practically all beekeepers are now using separators between each row of sections, no provisions are made in the grading rules for half and non-separated honey.

TO EXTRACTED-HONEY PRODUCERS.—Do not get honey contaminated by excessive use of smoke.

Be sure honey is thoroughly ripened and well strained before putting into cans.

Put sixty pounds net in each five-gallon can.

Adopt the plan of marketing each extracting with a different number or letter, as there is usually a variation of color and flavor in the different extractings. If a good-sized sample is kept of each lot with the mark and number of cans in lot on it, it is easy to satisfy an intending purchaser as to quality and color.

Cases should be nailed with 7-penny cement-coated box nails; and for long-distance local shipment the ends should be strapped with band iron or wire.

The grading of any article, honey not excluded, is a simple matter if the person doing the grading will follow the golden rule and put himself in the place of the buyer.

We note that the foregoing rules differ from former ones in the following particulars: They now provide for a "fancy white." The old rules did not go further than No. 1 white. They also provide for another grade—namely, "choice," as an intermediate grading between 1 and 2. Grading "fancy white" and "No. 1" provides for combs being attached to all four sides of the section. This is a most excellent requirement, and will do much to avert trouble between the producer and the buyer. No comb should be considered fancy or No. 1 unless it is attached to all four sides. And, again, we notice that the new rules as well as the old ones place a limit as to weight. The old rules provided for the limit on the case itself. The new rules provide a limit on the individual sections themselves. A little consideration will show that this is a decided improvement. In the first

place, a limit on the sections practically throws out all unseparated or half-separated honey. It renders it absolutely necessary, in order to get a grading of fancy and No. 1 and choice, that all supers on the hives be separated. Any producer who will attempt to go along the old lines in the production of honey without separators or half separators will find his product barred by the Colorado rules as now revised. The individual limit set on the sections as to weight will shut him out, because he can not afford to put into his cases a 15, 16, or 17 ounce section and get a credit of only $13\frac{1}{2}$ ounces. The underweight sections—those under $13\frac{1}{2}$ ounces—will not be accepted at all. Under the old grading rules a ten-ounce section and a fifteen-ounce section could both go into the same case, providing the whole case of 24 sections weighed not less than 22 lbs. net. Clearly the unseparated man is out-classed and ruled out. No more will the "average" be accepted. Hereafter every section in the case must come up to a certain limit; and not only that, combs must not project beyond the wood. They may weigh more than $13\frac{1}{2}$ ounces, but must not weigh less.

Another very important suggestion is that for scraping the sections. It should have been incorporated in the rules, for it is very important. It would raise the standard of the goods put on the market and shut out the slovenly beekeeper who will not take the pains to put his goods up in proper shape.

We are not sure but Eastern beekeepers, with some slight modifications, perhaps, could adopt these rules to advantage. In our judgment it would be an excellent idea for a committee of representative beekeepers and a committee of representative buyers to meet in Chicago and agree on some uniform system of grading. Both committees should be made up of Eastern and Western men as well as representatives from the South. It will be impossible for the producers to adopt a set of rules unless the large buyers are willing to accept them. There should be friendly co-operation, to the end that there may be a uniformity of product and a clear understanding of what is meant by a "fancy," a No. 1, a "choice," and a No. 2. This will avoid a great deal of misunderstanding, lawsuits, and put the business of comb-honey production on a safe and sane basis. GLEANINGS will be glad to co-operate with any intelligent movement toward bringing about a uniform system of grading; and we suggest that the Colorado rules be used as a basis.

Stray Straws

DR. C. C. MILLER, Marengo, Ill.

JUNE 14, instead of supers being now filled, no supers are on, and bees are not getting their daily bread.

QUEEN CULTURE is the poetry of bee culture; and he who is not a queen-rearer has not yet enjoyed the beauties of beekeeping. *Deutsche Bzcht.* [Very true.—Ed.]

NOSEMA APIS has not been taken very seriously on this side the water, although it has in Germany; and now comes a report of investigations by Dr. Graham-Smith, G. W. Bullamore, and others, that points strongly to nosema as the cause of the Isle-of-Wight disease.

DR. G. F. WHITE has finally cornered the culprit that causes European foul brood, and christened him *Bacillus pluton*. We now know that our old acquaintance, *Bacillus alvei*, is innocent of causing any bee disease, that *Bacillus larvae* is responsible for American foul brood, and I suppose Dr. White is hot foot after the fellow that gets up pickled brood. [See editorial comment on his bulletin last issue, page 360.—Ed.]

WALTER S. POWDER, you seem to think Texas beekeepers will not ship bulk comb honey out of the State. I wonder, now, if you should advertise for a carload how long you would have to wait for it, and after you got it I wonder how much of it you could sell. A grand success in Texas may not succeed everywhere. [As a matter of fact, Texas bulk honey does not come up to the North. Northern consumers would not buy it, for the simple reason that they are not "educated" to it. If we can imagine that 50 or 75 per cent of the Texas population were to move up into New York, it is very probable that there would be a carload, or several of them, of Texas bulk honey shipped into York State.—Ed.]

FRANK-KLEIST colored the thorax of some 80 bees. He found them scattered all over the apiary, only a few remaining at their own home. More than that, a neighbor found two of the marked bees making themselves at home in his apiary an eighth of a mile distant.—*Leipzig. Bztg.*, 66. One may be easily deceived into thinking that an Italian queen is impurely mated because dark bees are found in the hive. Look on the combs for the downy little fellows that have just hatched. If they're all right the older ones don't count. [We have known that the bees of neighboring colonies will intermingle to some extent. Where young bees by mistake

get into the wrong hive they are accepted without any hesitation; and it may be that old bees would be received in like manner. It is because of this intermingling that we have always advised treating the colonies neighboring to as well as the one affected with foul brood. Years ago, when we had disease in one of our yards, we would be pretty certain that the two or three colonies facing in the same direction, and right near the affected ones, would show up the disease sooner or later, simply because the bees of the diseased hive would carry the infection into the hives near by.—Ed.]
